Background and aims: Pigment epithelium-derived factor (PEDF) is recently identified as an adipokine of obese mice to induce insulin resistance (IR), the regulation of its own expression is largely unknown. Our previous studies suggest that early insulin therapy in type 2 diabetes mellitus subjects improve IR and decrease free fatty acids in the circulation. In this study, we aims to investigate the effects and underlying mechanisms of early insulin therapy on PEDF expression in white adipose tissue (WAT) of high fat diet and Streptozotocin (STZ)-induced diabetic Sprague-Dawley rats.

Materials and methods: We examined PEDF expression in fat tissue of STZ-induced diabetic rats before and after Neutral protamine Hagedorn insulin administration and in 3T3-L1 cell models after TNF- α and dexamethasone (DEX) treatments.

Results: Compared with normal ones, PEDF mRNA and protein expressions of WAT of untreated diabetic rats were increased by 9.2 and 4.1 fold, respec-

tively ($P<0.01$). After insulin administration, PEDF decreased significantly. Serum PEDF level was higher in diabetic rats, and inverted after insulin administration. Interestingly, the expressions of TNF- α , IL-6, iK κ B in WAT were up-regulated in untreated diabetic rats. They were down-regulated by the insulin treatment. Treatment of 3T3-L1 cells with TNF- α induce IR at the level of insulin-stimulated glucose uptake ability, which is paralleled by increased PEDF secretion and expression ($P<0.01$). This increase was also attenuated by insulin treatment. Time course study in vitro indicate that insulin decrease PEDF mRNA expression from 15min, 30min, 60min, while has no effects on PEDF expression after treatment for 2h. Using specific inhibitors, we found that PEDF expression was inhibited by insulin through PI3K-Akt signaling pathway, and NF-KB inhibitors PDTC can inhibit PEDF expression induced by TNF- α . PEDF expression was also increased by DEX ($P<0.05$) in fully differentiated 3T3-L1 cells in a time and dose dependent manner, which was attenuated by combination of Dex and insulin together.

Conclusion: PEDF level is elevated in both WAT of diabetic rats and 3T3-L1 cells with IR, which might through inflammatory factor NF- κ B signaling pathway. Insulin therapy might improve the insulin sensitivity by inhibiting PEDF expression.

Impact of Apo-CIII and Apo-E on insulin sensitivity: data from the RISC study

S. Baldi¹, C. Morgantini¹, M. Laville², F. Bonnet², E. Ferrannini¹, A. Natali¹, RISC investigators;

¹Department of Internal Medicine, University of Pisa, Italy; ²Service d'Endocrinologie-Diabétologie, Centre de Recherche en Nutrition Humaine, Rhône-Alpes, France.

Background and aims: Apolipoproteins may affect insulin sensitivity in opposite directions. ApoCIII knock-out mice develop insulin resistance and diet-induced obesity, while ApoE knock-out mice are protected. By inhibiting lipoprotein lipase, Apo-CIII might reduce tissue non-esterified fatty acids (NEFA) availability, whereas ApoE may induce lipid infiltration by promote lipoproteins transfer to extravascular tissues. We undertook to verify whether, and to what extent, Apo-CIII and ApoE modulate the impact of lipids on insulin sensitivity in man.

Materials and methods: In 1,017 non-diabetic subjects from RISC cohort (556 women and 461 men, age 44 ± 8 years, BMI 25.3 ± 3.8 kg/m²), we measured insulin sensitivity (euglycaemic clamp), physical activity (accelerometry), lifestyle habits (questionnaire), blood pressure (Omron), body composition (Tanita), lipid profile and apolipoproteins CIII and E (Multiplex suspension array technology, Luminex).

Results: HDL-cholesterol and triglyceride levels were related to insulin sensitivity, with similar strength but opposite sign ($r=+0.32$ and -0.30 , $p<0.001$ for both). In univariate analysis, ApoE and ApoCIII were only weakly associated with insulin sensitivity ($r=-0.14$ and -0.07 , respectively, $p<0.05$) despite their strong correlation with triglycerides ($r=+0.42$ and $r=+0.54$, $p<0.001$ for both). After adjusting for triglycerides, the association with insulin sensitivity was lost for ApoE (partial $r=-0.01$), while it became positive and stronger for ApoCIII (partial $r=+0.13$, $p<0.001$). The impact (standardised β coefficient) of the triglycerides adjusted ApoCIII on insulin sensitivity ($+9.5\pm 2.3$ $\mu\text{mol}\cdot\text{min}^{-1}\cdot\text{kg}_{\text{f}}^{-1}$, $p<0.0001$) was still positive and statistically significant ($+8.6\pm 2.9$ $\mu\text{mol}\cdot\text{min}^{-1}\cdot\text{kg}_{\text{f}}^{-1}$, $p<0.003$) after further adjusting for centre, age, sex, waist, blood pressure, smoking, physical activity and alcohol consumption. Interestingly, the removal of ApoCIII from the above mentioned model attenuated the negative impact of triglycerides on insulin sensitivity changing their standardized β coefficient from -19.9 ± 3.5 to -13.1 ± 2.2 to $\mu\text{mol}\cdot\text{min}^{-1}\cdot\text{kg}_{\text{f}}^{-1}$ ($p<0.05$). The ratio of serum NEFA to serum triglycerides (an index of intravascular lipolysis) showed a progressive decline through ApoCIII quartiles, however both ApoCIII and triglycerides, although attenuated, remained significant and opposite predictors of insulin sensitivity after adjusting also for serum NEFA.

Conclusion: The negative association of Apo-E with insulin sensitivity appears to be mediated through triglycerides levels. In contrast, Apo-CIII exerts an independent and positive effect on insulin action by attenuating the negative metabolic impact of triglycerides. ApoCIII inhibition of intravascular lipolysis of triglyceride-rich lipoproteins may at least in part explain this association.

Plasma levels of N ϵ -(carboxymethyl)lysine (CML) are lower in impaired glucose metabolism and type 2 diabetes and this is partly explained by obesity: the Hoorn and CODAM studies

L. Engelen^{1,2}, I. Ferreira^{1,2}, K.H.J. Gaens^{1,2}, J.M. Dekker³, G. Nijpels³, M.M.J. van Greevenbroek^{1,2}, C.J.H. van der Kallen^{1,2}, E.J.M. Feskens⁴, C.D.A. Stehouwer^{1,2}, C.G. Schalkwijk^{1,2};

¹Department of Internal Medicine, Maastricht University Medical Centre,

²Cardiovascular Research Institute Maastricht (CARIM), ³EMGO Institute, VU University Medical Center, Amsterdam, ⁴Division of Human Nutrition, Wageningen University, Netherlands.

Background and aims: Increased formation of advanced glycation endproducts (AGEs) constitutes a potential mechanism by which hyperglycaemia and its immediate biochemical sequelae induce micro- and macrovascular complications in diabetes. In type 1 diabetes, circulating levels of AGEs, including the major AGE N ϵ -(carboxymethyl)lysine (CML), have been shown to be increased and associated with the development of cardiovascular risk. In contrast, the exact role of circulating CML in type 2 diabetes (T2DM) remains unclear, because remarkably, so far no consistent data on levels of plasma CML have been described in individuals with vs. without T2DM. We have therefore investigated: 1) the extent to which levels of CML residues in plasma protein differed across different levels of impaired glucose metabolism and 2) the role of T2DM-related risk factors herein.

Materials and methods: We measured levels of CML residues in plasma protein, with the use of HPLC-tandem MS, in 1265 (568 women) individuals from two large population-based cohort studies in the Netherlands; subjects mean age was 64 ± 8 years, 46% of whom had normal glucose metabolism (NGM), 23% had impaired glucose metabolism (IGM) and 31% had T2DM. Data were analysed with multiple linear regression models.

Results: After adjustment for age, sex, prior CVD, HbA1c and use of glucose-lowering treatment, levels of CML were progressively lower in individuals with IGM and T2DM as compared with those with NGM (p -value for trend <0.001 ; Figure-model 1). These differences were significantly attenuated by about 50 and 47%, respectively, when further adjusted for waist circumference (Figure-model 2). Further adjustment for other risk factors (i.e. blood pressure, total:HDL cholesterol ratio, triglycerides, smoking and eGFR) and use of anti-hypertensive or lipid-lowering treatment did not materially change these differences, however (Figure-model 3). Similar results were found when analyses were stratified according to study population.

Conclusion: Levels of CML residues in plasma protein decrease with increasing levels of impaired glucose metabolism and this seems to be partly explained by the increasing levels of central obesity in these individuals. The underlying mechanisms explaining these observations and the role of (central) obesity herein require further investigation.

Figure. Differences between IGM or T2DM vs. NGM in plasma CML.

Model 1 is adjusted for age, sex, prior CVD, HbA1c and use of glucose-lowering treatment; model 2 is additionally adjusted for waist circumference; model 3 is the fully adjusted model (i.e. additionally adjusted for blood pressure, total:HDL cholesterol ratio, triglycerides, smoking, eGFR and use of anti-hypertensive or lipid-lowering treatment).

Divergent effects of μ -opioid antagonism on insulin secretion from human islets and efficacy in type 2 diabetic patients

K. Bokvist, F. Zhang, M.A. Statnick, M.E. Christe, C.H. Mitch, W. Shen, X. Peng, H.-R. Qian, J.K. Leohr, J.W. Miller;
Lilly Research Laboratories, Indianapolis, USA

Background and aims: Opioid receptors have been implicated in both weight and glycaemic control in rodents and humans. Recently, μ opioid receptor knock-out mouse data and early clinical data with naloxone suggest that antagonizing opioid receptors may improve islet function and insulin secretion in humans. We have therefore evaluated 1) what are the opioid receptor subtypes expressed in human islets; 2) what is the direct effect of opioid receptor activation and blockade on insulin secretion in isolated human islets; and 3) to what extent opioid receptor blockade acutely improves islet function and glycaemic control in a pilot study in a cohort of type 2 diabetic patients.

Material and methods: Rat islets were prepared from Sprague-Dawley rats and used the day after isolation for insulin secretion. Human islets were procured from cadaver donors that had volunteered for organ donor programs and allowed to recover in culture overnight prior to secretion experiments or RNA extraction. In the human study, which ran in Singapore, patients were evaluated using a blinded randomized cross-over design where post-prandial blood glucose and insulin following a test meal were measured in each patient. All patients received placebo, naloxone, methylnaltrexone or repaglinide in a random order.

Results: In human islets the μ -opioid receptor was the predominantly expressed opioid receptor with no detectable transcripts of other opioid receptors (δ , κ & λ). Human islets furthermore expressed the POMC gene that may be processed to the opioid receptor ligand endorphin. No detectable levels of the PENK gene (enkephalin) were found. The opioid receptor agonist loperamide (1 μ M) suppressed insulin secretion from rat islets by $\approx 75\%$. In human islets 10 μ M loperamide suppressed insulin secretion by $\approx 50\%$. An opioid receptor antagonist was able to reverse the inhibition seen with loperamide. In a cohort of type 2 diabetics, who were randomized in a cross-over study design to placebo, repaglinide, naloxone or the peripherally restricted opioid antagonist methylnaltrexone, we failed to observe any improvements in post-prandial insulin or C-peptide levels over placebo following a test meal with naloxone or methylnaltrexone treatment. In contrast, repaglinide treatment (the positive control) significantly enhanced plasma insulin and C-peptide levels by 72% and 40%, respectively ($P < 0.002$).

Conclusion: Our data suggests that μ opioid receptors are expressed in human islets. As μ -opioid receptors are known to couple through an inhibitory G protein, this is the likely mechanism by which loperamide suppresses insulin secretion *in vitro*. However, in a clinical setting, it appears unlikely that inhibiting the islet opioid receptor pool with an opioid receptor antagonist acutely enhances glycaemic control in type 2 diabetic patients.

Autocrine inhibitory effects of proinsulin C-peptide and insulin on insulin secretion and pancreatic beta cell function

A.M. McKillop, M.T. Ng, P.R. Flatt, Y.H.A. Abdel-Wahab;
School of Biomedical Sciences, University of Ulster, Coleraine, UK.

Background and aims: C-peptide and insulin are released from pancreatic islets in equimolar amounts after proinsulin is processed by prohormone convertases and carboxypeptidase E. Many regulatory peptides are known to have a feedback mechanism however there is a lack of consistent evidence demonstrating the intra-islet effects of C-peptide and insulin. The present study was undertaken to explore the actions of proinsulin C-peptide and insulin on pancreatic beta cell function.

Materials and methods: Insulin releasing activity of C-peptide (human, rat-1 and rat-2) and insulin were studied in pancreatic islets isolated from normal Swiss TO mice ($n=5$) and results confirmed using the clonal pancreatic cell line, BRIN-BD11. Acute insulin secretion studies were performed at 5.6mM and 16.7mM glucose. A range of C-peptide and insulin concentrations were tested with various insulin secretagogues. Insulin and C-peptide release were both measured by radioimmunoassays. *In vivo* glucose and insulin responses were assessed in fasted Swiss TO mice following i.p. glucose (18mmol/kg) and C-peptide (25nmol/kg) or insulin (25nmol/kg).

Results: Acute exposure of isolated islets to insulin resulted in inhibition of alanine(10mM)-stimulated C-peptide release at 5.6mM glucose (10^{-9} - 10^{-6} M, $p < 0.05$ - $p < 0.001$) and IBMX (200 μ M)-stimulated C-peptide release at 16.7mM glucose (10^{-10} - 10^{-6} M, $p < 0.05$ - $p < 0.001$). Inhibition of C-peptide secretion in the presence of insulin (3×10^{-7} M) was accompanied by suppression of the insulin-secretory response to alanine (10mM, $p < 0.05$) and GLP-1 (10^{-8} M, $p < 0.05$) at 5.6mM glucose, and IBMX (200 μ M, $p < 0.001$) at 16.7mM glucose. Like insulin, in isolated islets, C-peptide (3×10^{-7} M) inhibited insulin secretion at 5.6mM ($p < 0.001$) and 16.7mM ($p < 0.001$) glucose. Inhibition of glucose-induced insulin secretion with C-peptide (3×10^{-7} M) was accompanied by suppression of the insulin-secretory responses to alanine (10mM, $p < 0.01$), GIP (10^{-8} M, $p < 0.01$) and tolbutamide (200 μ M, $p < 0.01$) at 5.6mM glucose. Likewise, C-peptide (3×10^{-7} M) inhibited insulin release induced by IBMX (200 μ M, $p < 0.05$) at 16.7mM glucose. Similar results were found using clonal beta cells and the observations made with human C-peptide were reproduced using rat C-peptide-1/-2. Insulin (3×10^{-7} M) reduced cAMP production in the presence of glucose (16.7mM, $p < 0.001$), GLP-1 ($p < 0.01$) and forskolin ($p < 0.001$) whereas C-peptide (3×10^{-7} M) had no effect. Acute exposure of clonal beta cells to insulin resulted in a decrease in insulin mRNA expression in the presence of alanine at 5.6mM ($p < 0.01$) and 11.1mM ($p < 0.01$) glucose. Human C-peptide (3×10^{-7} M) had no effect. In mice, administration of insulin together with glucose decreased plasma glucose at 15min ($p < 0.001$), 30min ($p < 0.001$) and 60min ($p < 0.001$), compared to glucose alone. Area under the curve (AUC) confirmed reduced plasma glucose ($p < 0.001$) and C-peptide ($p < 0.01$). Similarly, the glycaemic response was impaired by administration of C-peptide (1.3-fold, $p < 0.001$). AUC analysis revealed a decreased insulin response following administration of C-peptide ($p < 0.001$).

Conclusion: This study provides evidence that insulin and C-peptide exert inhibitory effects on pancreatic beta cell function and glucose-stimulated insulin release mediated through intracellular signalling pathways, contributing to the multifactorial regulation of the pancreatic beta cell.

632

Insulin-induced stimulation of insulin secretion, its relation to insulin sensitivity and impact on impaired glucose regulation

A. Mari¹, A. Tura¹, A. Natali², B. Balkau³, N.M. Lalic⁴, M. Walker⁵, E. Ferrannini², RISC Investigators;

¹Institute of Biomedical Engineering, National Research Council, Padova, ²Department of Medicine, University of Pisa, Italy, ³INSERM U 258, Villejuif, France, ⁴Institute for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, ⁵Department of Medicine, University of Newcastle upon Tyne, UK.

Background and aims: In islets of mice with selective knock out of beta-cell insulin receptors, glucose-induced insulin release is impaired. Recent work has shown that insulin stimulates its own secretion in humans and has suggested that insulin resistance in the beta cell could be an important cause of beta-cell dysfunction. We have analysed the RISC study database to test whether insulin exposure and insulin sensitivity modulate beta-cell function in subjects with normal glucose tolerance (NGT) and contribute to the dysglycaemia of subjects with impaired glucose regulation (IGR, impaired fasting glycaemia and/or impaired glucose tolerance).

Materials and methods: Insulin sensitivity (M, by euglycaemic insulin clamp), endogenous insulin release during the clamp (as C-peptide concentration percent change from basal; positive change = stimulation, negative = suppression) and beta-cell glucose sensitivity (β GS, by modelling of the C-peptide response during the OGTT) were measured in 1151 NGT and 163 IGR men and women.

Results: In NGT, insulin-induced suppression of C-peptide was strongly inversely related to both M and the steady-state plasma insulin concentration during the clamp. In a multivariate model controlling for centre, sex, age, BMI and steady-state plasma glucose levels, each standard-deviation increment in plasma insulin and M was associated with a 5% and 23% increase in the C-peptide response, respectively ($p=0.008$ and $p<0.0001$). The C-peptide response was positively, if weakly, related to β GS ($r=0.16$, $p<0.0001$). Both the C-peptide response ($-16 \pm 5\%$ vs $9 \pm 2\%$, $p<0.0001$) and β GS (81 ± 7 vs 139 ± 3 pmol min⁻¹ m⁻² mM⁻¹, $p<0.0001$) were decreased in IGR in comparison with NGT. After adjustment for confounders, M and β GS were the major determinants of mean OGTT glucose levels in both NGT and IGR; however, the contribution of the latter was significantly ($p<0.05$) greater in IGR than NGT (59% vs 38% for each standard-deviation decrement in β GS), with a minor role of the C-peptide response. In a multivariate logistic model, IGR was predicted by β GS (odds ratio = 4.84 [95% CI = 2.89-8.09]) and M (odds ratio =

3.06 [95% CI = 2.19–4.27]) but not by the C-peptide response (odds ratio = 1.11 [95% CI = 0.77–1.61]).

Conclusions: Pre-exposure to physiological hyperinsulinaemia stimulates insulin secretion to a degree that is strongly dependent on insulin sensitivity. However, this phenomenon has limited impact on beta-cell dysfunction and dysglycaemia.

***In vivo* activation of PKA in beta cells rescues glucose intolerance by enhancement of insulin secretion with no effect on beta cell mass**

K.A. Kaihara, L.M. Dickson, C.M. Orr, B.L. Wicksteed;
Medicine, The University of Chicago, USA.

Background and aims: β -cell dysfunction and insulin resistance contribute to impaired glucose tolerance (IGT) and precede the onset of type 2 diabetes mellitus (T2DM). Potential for β -cell based therapies have focused upon increasing insulin secretion pharmacologically or expanding β -cell mass. However, certain diabetic therapies that target the β -cell, such as sulfonylurea treatment, raise the risk of hypoglycemia and lose efficacy over time, while expanding β -cell mass in mice leads to hyperinsulinemia and β -cell tumorigenesis. Here a mouse model (β -caPKA mice) of tamoxifen inducible, β -cell specific constitutive protein kinase A (PKA) activity exhibited improved and sustainable β -cell function through enhanced insulin secretion with unaltered β -cell mass.

Materials and methods: Tamoxifen was i.p. injected into β -caPKA mice and three littermate control lines to activate the constitutively active PKA transgene in β -caPKA mice. IPGTTs were assessed using 1 g/kg body weight in overnight fasted mice and sampling from the tail vein. β -cell mass was determined in histological sections by quantifying insulin positive versus total pancreas area, and total pancreatic insulin content was measured.

Results: Intraperitoneal glucose tolerance tests (IPGTT) after tamoxifen administration revealed an increase in plasma insulin levels in β -caPKA mice versus wildtype controls at 2 (2251 ± 547 pg/ml vs. 658 ± 190 pg/ml; $p < .05$) and 5 (1507 ± 377 pg/ml vs. 635 ± 184 pg/ml; $p < .05$) minutes with no differences observed at later timepoints. This enhancement in glucose-stimulated insulin secretion in β -caPKA mice resulted in a statistically significant decrease in blood glucose levels from 10–60 minutes versus controls, indicating improved glucose tolerance. These effects were sustainable up to 52-weeks of age with no indications of hyperinsulinemia, hypoglycemia, beta-cell exhaustion, or the development of insulinomas. To determine whether enhanced insulin secretion could overcome pre-existing glucose intolerance, β -caPKA mice and wildtype controls were placed on a 45% high fat diet (HFD) for 16 weeks after which tamoxifen was administered. IPGTTs administered 4 weeks later after continual high fat feeding revealed increased insulin secretion at the 2 (4844 ± 1828 pg/ml vs. 951 ± 388 pg/ml; $p < .05$) and 5 (3438 ± 1297 pg/ml vs. 1073 ± 438 pg/ml; $p < .05$) minute timepoints in β -caPKA mice versus wildtype controls with no differences at later timepoints. This enhancement of insulin secretion improved glucose tolerance in 34-week old, high fat fed β -caPKA mice (177 ± 72 mg/dl at 20 minutes) versus wildtype controls (411 ± 168 mg/dl at 20 minutes), and remarkably restored glucose tolerance to the same level observed in 9-week old, chow fed β -caPKA mice (246 ± 82 mg/dl at 20 minutes). β -cell mass increased after high fat feeding but was not different between β -caPKA mice and wildtype controls.

Conclusions: Increasing PKA activity in the β -cell leads to enhanced insulin secretion *in vivo* and was achieved without indications of hyperinsulinemia of hypoglycemia, β -cell exhaustion or the development of insulinomas. Glucose intolerance induced by HFD was fully reversed following tamoxifen induction of the increased β -cell PKA activity in β -caPKA mice, with no differences on β -cell mass between wildtype controls. Thus therapies that solely target β -cell function can fully reverse glucose intolerance without the adverse consequences associated with other treatment strategies.

Analysis of glucose homeostasis in p66-ko mice reveal a major role of p66shc in nutrient sensing

G. Sorice¹, G. Muscogiuri¹, C. Baracaa², A. Giaccari¹, G. Pani²;

¹Endocrinology, ²General Pathology, Catholic University, Rome, Italy.

Background and aim: The longevity determinant p66shc has a role in insulin signaling and contributes to peripheral insulin desensitization and to the establishment of type 2 diabetes in obese mice. Although the recently discovered biochemical linkage with the mammalian Target of Rapamycin (mTOR) and its downstream nutrient sensitive effector S6 kinase (S6K) suggest the involvement of p66 also in “normal” glucose metabolism and in glucose sensing and insulin secretion by pancreatic beta cells, these possibilities still need to be verified.

Methods and aims: In order to investigate the relevance of p66shc to glucose homeostasis in healthy animals, lean WT and p66KO mice were subduced to a) euglycemic/hyperinsulinemic clamp and b) to hyperglycemic clamp, the two “gold standard” assays for, respectively, peripheral insulin sensitivity and pancreatic beta cell secretory response.

Results: Peripheral response to Insulin was significantly upregulated in p66KO mice compared to wild type controls (glucose uptake: 141.9 ± 62.3 versus 56.1 ± 23.4 mg/Kg⁻¹/min⁻¹, $p < 0.02$), a finding also corroborated by a significant reduction in the level of basal fasting glycemia (85 ± 7.9 mg/dl versus 108.5 ± 9.8 mg/dl) in the presence of comparable plasma insulin, in this strain. Interestingly, under hyperglycemic stress, a clear tendency to a reduced insulinemic response, both in the early (15') and late phase (50–90') of the curve, was observed in p66-deficient mice, consistent with a blunted response of beta cells to glucose load.

Conclusion: If confirmed in larger numbers of animals, this complex phenotype, that strikingly mirrors that of mice harboring defects in the mTOR/S6K signaling cascade, suggests that p66shc, by interfering with nutrient sensing, regulates both tissue response to insulin and glucose-induced insulin secretion. These findings have major implications for the genetics and treatment of type 2 diabetes.

Deletion of beta-arrestin-2 impaired glucose induced insulin secretion from pancreatic islet cells

C. Wang^{1,2}, M. Zhang^{1,2}, L. Li^{1,2}, Y. Zhu^{1,2}, J. Zhao³, W. Jia^{1,2};

¹Department of Endocrinology and Metabolism, Shanghai Jiao Tong

University Affiliated Sixth People's Hospital, ²Shanghai Diabetes Institute,

³Laboratory of Molecular Cell Biology, Institute of Biochemistry and Cell Biology, Shanghai, China.

Background and aims: Beta-arrestin-2 is an adaptor protein with multiple functions. Deficiency of beta-arrestin-2 in mice has been reported to induce glucose intolerance by disturbance of insulin signaling. Since beta-arrestin-2 is also expressed in pancreatic beta-cells, the aim of the study was to determine the effect of beta-arrestin-2 on function of pancreatic beta-cells.

Materials and methods: Beta-arrestin-2 knockout (KO) and littermate wild-type (WT) mice were used for the present study. Hyperglycemic clamps were performed over a 90-min period as previously described on 6h-fasted mice to evaluate the beta-cell function *in vivo*. The targeted glucose levels were 16–18 mmol/L. Islets from beta-arrestin-2 KO mice were isolated to measure glucose and forskolin (FK) induced insulin release.

Results: Beta-arrestin-2 protein expression increased in pancreatic islet cells from high fat diet mice. As previous reported glucose intolerance was observed in beta-arrestin-2 deficient mice compared with WT although the 6h-fasting insulin level was comparable between KO and WT mice. Hyperglycemic clamp test showed that both the acute phase ($AUC_{0-20min}$) and late phase insulin secretion ($AUC_{20-90min}$) decreased from KO mice (acute phase: 4.17 ± 0.63 ug/L; late phase: 11.08 ± 1.71 ug/L) compared with those from WT mice (acute phase: 11.69 ± 2.80 ug/L; late phase: 29.61 ± 5.31 ug/L) (all $p < 0.01$, $n = 7-12$). No difference could be found in insulin content from pancreas between KO and WT mice. To understand the role of beta-arrestin-2 on beta cell function, islets from beta-arrestin-2 KO mice were isolated and cultured at low (G6.1) and high glucose (G20) concentrations overnight. Consistent with the finding *in vivo*, glucose induced insulin release decreased ($p < 0.05$, $n = 6$) in beta-arrestin-2 KO mice (53.73 ± 10.08 ug/mg protein) compared with wild type littermates (28.34 ± 6.66 ug/mg protein). Moreover, insulin secretion induced by FK was blunted from KO islets (42.37 ± 9.01 ug/mg protein) compared with that from WT islets (75.61 ± 15.62 ug/mg protein) ($p < 0.02$, $n = 5$).

Conclusion: The results indicated that beta-arrestin-2 was involved in insulin secretion stimulated by glucose.

Toxic consequences of the atypical maturation and disposal process of proinsulin in the *Ins2^{+/-Akita}* beta cells

Q. Yuan^{1,2}, W. Tang^{1,2}, X. Zhang¹, K. Osei¹, J. Wang¹;

¹Division of Endocrinology, Diabetes, and Metabolism, The Ohio State University, Columbus, USA, ²Division of Endocrinology, The First Affiliated Hospital of Nanjing Medical University, China.

Background and aims: Proinsulin is the most abundant insulin precursor made in β -cells. The processing of proinsulin molecules involves a complex process of “folding.” Until recently, this was felt to occur very rapidly, resulting in formation of mature insulin molecules. We recently reported that proinsulin preserves an aggregation-prone nature and a low relative folding rate that result in production of abundant non-natively folded non-monomer (i.e., aggregate) forms. Thus, proinsulin maintains a homeostatic balance of natively and non-natively folded states (i.e., proinsulin homeostasis, PIHO) in normal β -cells as a result of the integration of disposal and maturation processes. We have also revealed the susceptibility of PIHO to various (non)genetic factors. Based on our accumulated evidence, we have suggested that PIHO, an early post-translational regulation mechanism in insulin biosynthesis, may critically link to diabetes. To provide supporting evidence for this hypothesis, in this study we characterized what cytotoxic consequences result from the primarily disturbed PIHO in the *Ins2^{+/-Akita}* β -cells with a genetic disorder (C96Y) in the *Ins2* gene.

Materials and methods: We applied quantitative PCR, metabolic-labeling, immunoblotting, and other biochemical and morphological studies in the cloned *Ins2^{+/-Akita}* and control *Ins2^{+/+}* β -cell lines. Statistical analyses are performed using Student's t-test (2-tailed) or analysis of variance if appropriate, with $P < 0.05$ considered statistically significant.

Results: We have found that the primarily disturbed PIHO in the *Ins2^{+/-Akita}* β -cells results in a decrease ($P < 0.01$) in the levels of cellular (pro)insulin and secreted insulin, and increases ($P < 0.01$) of cellular (pro)insulin disposals and the secreted proinsulin/insulin ratio notwithstanding no obvious attenuations of transcription and translation. There are other consequences in the *Ins2^{+/-Akita}* β -cells. These include the enlargement of endoplasmic reticulum (ER), Golgi, and mitochondria organelles, the decrease of insulin granules in the number and size, and the increase ($P < 0.01$) of the reactive oxygen species, thioredoxin-interacting protein, tyrosine-nitrated proteins, and β -cell death rate.

Conclusion: Our studies demonstrate that the abnormalities in insulin production and mitochondrial morphology, ER and/or oxidative stress, and β -cell depletion resulted directly from PIHO disorders without secondary contributions of glucotoxicity. This is because that the cloned *Ins2^{+/-Akita}* and control *Ins2^{+/+}* β -cells were subjected to same concentrations of glucose in culture and to same treatments in this study. The data suggest that proinsulin maturation and disposal disorders (induced by various factors) results in a number of consequences that contribute to the development of β -cell failure and diabetes.

Delta-cell secretory responses to insulin secretagogues are not mediated indirectly by insulin

A.C. Hauge-Evans, R. Anderson, I. Schim van der Loeff, S.J. Persaud, P.M. Jones;

Diabetes Research Group, King's College London, UK.

Background and aims: Little is known about the regulation of somatostatin (SST) secretion from pancreatic delta cells although a range of insulin secretagogues has been reported to stimulate SST release. The aim of the study was to assess whether the similarity in the secretory response from delta and beta cells is due to an indirect effect of insulin on SST release.

Materials and methods: Mouse islets were isolated by collagenase digestion. Hormone secretion from primary islets or the TGP52 delta-cell line was assessed in static incubation studies. Insulin, glucagon and SST release was measured by radioimmunoassay (RIA).

Results: Incubation with exogenous insulin (100 nmol/l) did not modulate glucose-induced SST release from mouse islets (1 mmol/l glucose (G):

1.14±0.04 fmol SST/islet/h; 1 mmol/l G + insulin: 1.02±0.08; 20 mmol/l G: 2.98±0.27; 20 mM G + insulin: 2.75±0.36, $P > 0.2$ vs. 1 and 20 mmol/l G, respectively). The lack of effect was not due to binding of endogenous insulin to the insulin receptor since preincubation with either the insulin receptor tyrosine kinase inhibitor HNMPA(AM)₃ (10 μ mol/l, 1 h) or an insulin receptor antibody (IRAB, 1 μ g/ml, 48h) did not alter the secretory response of the islets to glucose (1 mmol/l: 0.97±0.08 fmol SST/islet/h; 1 mmol/l + HNMPA(AM)₃: 1.27±0.25; 1 mmol/l + IRAB: 1.21±0.16; 20 mmol/l: 1.95±0.22; 20 mmol/l + HNMPA(AM)₃: 1.64±0.32; 20 mmol/l + IRAB: 2.47±0.22; $P > 0.2$). In the same experiments HNMPA(AM)₃ did not modulate glucose-induced inhibition of glucagon secretion (1 mmol/l G: 23.9±1.8 pg/islet/h; 1 mmol/l G + HNMPA(AM)₃: 21.2±2.4; 20 mmol/l G: 13.4±1.4; 20 mmol/l G + HNMPA(AM)₃: 12.8±1.4; $P > 0.2$ vs. controls) nor did IRAB alter the response to glucose or arginine (20 mmol/l G: 48.7±3.5; 20 mmol/l G + IRAB: 37.2±3.2; 20 mmol/l arginine: 122.8±11.5; 20 mmol/l arginine + IRAB: 113±7.8, $P > 0.08$ vs. 20 mmol/l G, $P > 0.2$ vs. 20 mmol/l arginine). In contrast, glucose-induced insulin secretion was significantly enhanced following preincubation with HNMPA(AM)₃ (20 mM G: 2.53±0.27; 20 mM G + HNMPA(AM)₃: 4.28±0.34; $P < 0.001$) although no effect was observed with IRAB (20 mmol/l G: 2.08±0.27; 20 mmol/l G + IRAB: 1.79±0.35; $P > 0.2$). To exclude other potential interactions between beta- and delta-cells, secretion experiments were carried out with the TGP52 delta cell line to assess whether the SST secretory profile was maintained in the absence of any beta cell input. Similar to the response of primary islets, glucose and tolbutamide stimulated SST release from TGP52 cells (1 mmol/l G: 3.9±0.16 fmol SST/100,000 cells/h; 20 mmol/l G: 7.45±0.49; 100 μ mol/l tolbutamide: 8.85±0.87, $P < 0.001$) and glucose-induced secretion was inhibited by 10 μ mol/l NA (20 mmol/l G + NA: 5.35±0.13 fmol/100,000 cells/h; $P < 0.01$).

Conclusion: These data imply that the similarity in secretory responses of beta- and delta-cells is not due to an indirect action of insulin (or other beta-cell specific secretory products) on the delta-cell. Alternatively, similar stimulus-response coupling pathways are operating in the two different islet cell types. Our results also indicate that endogenous insulin is not mediating the inhibitory action of glucose on glucagon secretion but may negatively regulate insulin release.

In situ electrophysiological examination of pancreatic α cells in type 1 diabetes revealing the cellular basis of glucagon hypersecretion

Y.-C. Huang¹, M. Rupnik², P. Herrera³, P. Gilon⁴, H. Gaisano⁵;

¹Medical Science, University of Toronto, Canada, ²Institute of Physiology, Department of Medicine, University of Maribor, Slovenia, ³Cell Physiology & Metabolism, University of Geneva, Switzerland, ⁴Unité d'Endocrinologie et Métabolisme, University of Louvain, Brussels, Belgium, ⁵Medicine and Physiology, University of Toronto, Canada.

Aims: To characterize voltage-gated ion channels in α cells of Type 1 Diabetic (T1D) mouse model and understand how these channels are altered to collectively lead to hyperglucagonemia in the early stage of diabetes.

Materials and methods: GYY mouse model, which expresses EYFP specifically in pancreatic α cells, was employed to facilitate the identification and localization of α cells. T1D was induced by low dose (40mg/kg) Streptozotocin (STZ) treatment for 5 consecutive days. T1D development was monitored by fed and fasting blood glucose, blood glucagon levels and IPGTT. Islet α cell mass and morphology by confocal microscopy and total pancreatic glucagon content were assessed. Pancreas tissue slices were prepared from control and diabetic mice to enable in situ examination of a cell electrophysiology by standard whole-cell patch-clamp technique.

Results: STZ-treatment caused T1D phenotype including fed and fasting hyperglucagonemia (control vs. STZ-group; fasting: 67±3.4 vs. 121±20 pg/ml; fed: 128±11.6 vs. 220±32.7 pg/ml, $P < 0.05$), hyperglycemia (control vs. STZ-group; fasting: 11.7±1.7 vs. 17.7±1.7 mmol/L; fed: 10.1±0.5 vs. 28.7±1.5 mmol/L, $P < 0.001$) and glucose intolerance measured by IPGTT. While 71% of β cell mass was ablated by STZ treatment, a cell mass was not significantly changed in diabetic mice (control vs. STZ-group; 2.9±0.5 vs. 2.4±0.24 mg). However, total pancreatic glucagon content was elevated in T1D (control vs. STZ-group; Total-Gluc: 4.6±0.3 vs. 27.6±9.1 pg/ μ g, $P < 0.001$). Taken together with the normal α cell size in the diabetic mice as measured by membrane capacitance (C_m) (control vs. STZ-group; 4.7±0.2 vs. 4.9±0.2 pF), this indicates that each α cell contained elevated glucagon content. Single α cell glucagon granule exocytosis examined by serial depolarization-induced ΔC_m was increased in α cells of diabetic mice. Consistently, static incubation of pancreas

slices at stimulatory 3mM glucose showed higher glucagon secretion from the diabetic α cell populations. Electrophysiological studies on individual α cells suggested that α cells in diabetic mice expressed larger voltage-gated Na current (control vs. STZ-group; 72.2 ± 7.6 vs. 86.7 ± 10.0 pA/pF, $P < 0.05$). Voltage-gated K current was significantly reduced in α cells of diabetic mice (control vs. STZ-group; 485 ± 46 vs. 416 ± 35 pA/pF, $P < 0.05$). Membrane potential recording revealed increased action potential (AP) duration, amplitude and firing frequency in α cells of diabetic mice.

Conclusions: Hyperglucagonemia in T1D is contributed by the following perturbation in α cell physiology. First, each α cell in T1D has upregulated glucagon content that can be released when triggered. Second, α cell membrane ion channel machinery (AP firing frequency, amplitude and duration) is primed for glucagon release in response to low glucose stimulation. Third, the primed glucagon release is contributed by the larger Na current that sensitizes towards action potential firing, and reduced voltage-gated K current which slows membrane repolarization after AP firing thus prolonging AP duration.

Systemic effects of liver regeneration on rat beta cells and islets: *in vivo* and *in vitro* studies

F. Moreau^{1,2}, F. Toti³, W. Bietiger², E. Seyfritz², S. Sigrist², N. Jeandier^{1,2}, M. Pinget^{1,2}, L. Kessler^{1,2};

¹Department of Endocrinology and Diabetology, University Hospital and Faculty of Medicine of Strasbourg University, ²Cellular and Genetic Laboratory, Centre Européen d'Etude du Diabète, ³INSERM U770 Hematology and Immunology Institut, Strasbourg University, Strasbourg, France.

Background and aims: Liver regeneration induces the release of humoral factors *in situ* and in blood circulation possibly influencing pancreatic function. Liver regeneration involves adaptation of glucose metabolism. This work studies the systemic effect of liver regeneration on the native pancreas in normal rats. *In vitro*, the outcome of rat RINm5F beta cells, grown in standard medium supplemented with normal or diabetic hepatectomized (Hx) rat serum and insulin secretion of Hx rat islets are examined.

Materials and methods: 2/3 partial hepatectomy was performed in normal and streptozotocin induced diabetic Lewis rats (n=6). Pancreas from control, SHAM or Hx normal rats were weighted 1, 2 or 3 days after surgery, islets size examined by insulin staining. RINm5F cells were grown in RPMI medium containing 10% serum from Hx or SHAM rats. After 24 h, cell viability and count were evaluated by CellTiter^R and cell counter. Glucose-stimulated insulin release from islets isolated three days after Hx or control rats was studied. **Results:** The ratio pancreas/body weight was higher in Hx rats compared to SHAM, 3 days after surgery: 0.58 vs 0.39 (p=0.057). After partial hepatectomy, proportion of small size islets (<10 000 μ m²) increased significantly from 76% to 90% (p < 0.05) (control vs 3 days post Hx). By comparison with the serum obtained from Sham animals, Hx normal rat serum promoted a significant increase in RINm5F cell viability: 126% vs 94% (p=0.005) and cell proliferation : 4.62 vs 3.54×10^5 cells / ml (p=0.036) (n=6), with serum withdrawn 2 days after surgery. Conversely, Hx diabetic rat serum withdrawn 3 days after hepatectomy had an opposite effect with significant decrease in cell viability: 79 vs 95% (p=0.036). Insulin release in low-glucose medium trends to be higher for Hx rats islets compare to control rats islets: 28 vs 16 ng/ml/10 islets p=NS. No difference was found for insulin stimulation index.

Conclusion: Liver regeneration induces systemic effects on pancreatic islets and increases their viability in normal rat but not in diabetic rat. Further studies on islet functionality must be achieved on rat islets isolated after partial hepatectomy.

PS 044 Hypoglycaemia: clinical aspects

A higher counter-regulatory hormone response is seen with insulin degludec than insulin glargine in response to induced hypoglycaemia in type 1 diabetes

S.R. Heller¹, T. Pieber², S. Korsatko², G. Köhler², S. Deller², G. Bock², S. Zahiragic², J. Mader², C. Roepstorff³, S. Rasmussen³, H. Haahr³;

¹School of Medicine and Biosciences, University of Sheffield, UK,

²Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical University of Graz, Austria, ³Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Intensified insulin therapy can often have side effects, of which hypoglycaemia remains the most prominent. An appropriate hormonal counter-regulatory response plays an important role in glucose recovery. We conducted a double-blind, two-period, crossover trial to investigate the counter-regulatory hormone responses elicited during a period of hypoglycaemia induced by insulin glargine (IGlar) or the ultra-long-acting basal insulin, insulin degludec (IDeg).

Materials and methods: A total of 28 subjects with type 1 diabetes (age 41 ± 12 years, diabetes duration 21 ± 10 years, HbA_{1c} $7.8 \pm 0.6\%$) were randomised to receive either IDeg or IGlar once daily for 5 days. At midnight on Day 5, each individual received an insulin dose which was three times higher than their personal daily requirement. A variable intravenous glucose infusion was used to maintain euglycaemia at 5.5 mmol/l for the next 7 hours. After this period, glucose infusion was terminated to lower plasma glucose (PG) to 3.5 mmol/l (kept for a duration of 30 min) and then to 2.5 mmol/l (for 15 min). PG was then raised to 3.9 mmol/l, where it was maintained for 2 h, before a further elevation to 5.5 mmol/l. Hormonal counter-regulation was assessed at baseline and at PG levels from 4.5–2.5 mmol/l.

Results: Rate of PG decline and the lowest PG level obtained were comparable between IDeg and IGlar. Noradrenaline and glucagon responses were similar for both IDeg and IGlar. However, levels of both growth hormone and cortisol secretion during hypoglycaemia (from PG 4 mmol/l to 2.5 mmol/l) were significantly higher with IDeg compared with IGlar, with respective AUC_{hormone} [ng*min/ml] values of 498 vs. 204 (treatment ratio (TR) IDeg/IGlar: 2.44 [1.30; 4.60] p<0.01) for growth hormone and 10834 vs. 8808 (TR: 1.23 [1.01; 1.50] p<0.05) for cortisol. In addition, there was an observed trend towards a higher adrenaline response for IDeg compared with IGlar, which failed to reach statistical significance (AUC [pg*min/ml]: 6636 vs. 4726 (TR: 1.40 [0.96; 2.04] p=0.07)). Under hypoglycaemic conditions (PG 2.5 mmol/l), glucose infusion rates for both insulins were comparable; however, less glucose was required to alleviate hypoglycaemia with IDeg than with IGlar during the recovery phase (AUC_{GIR} [mg/kg]: 201 vs. 285, respectively, (TR: 0.71 [0.53; 0.93] p<0.02)).

Conclusion: In people with type 1 diabetes, induction of hypoglycaemia with IDeg results in a significantly greater counter-regulatory hormone response compared with IGlar. This observation indicates that enhanced counter-regulation may contribute to the observed reduced hypoglycaemia risk for IDeg compared with IGlar.

Prolonged hypoglycaemic activity of the novel insulin analogues: preliminary study on animal diabetes model

M. Bogiel¹, M. Pawłowska¹, M. Bujalska-Zadrozny², D. Mikiewicz¹, D. Kurzynoga¹, J. Szewczak¹, P. Borowicz¹;

¹Institute of Biotechnology and Antibiotics, ²Department of Pharmacodynamics, Medical University of Warsaw, Poland.

Background and aims: Using modified insulin with a potentially prolonged pharmacological action, that could maintain basal level of glucose for more than one day, seems to be interested and advantageous in clinical practice. The objective of the study was to evaluate pharmacological effects of the new long-acting insulin analogues, taking into account particularly the length of the action after stopping their administration.

Materials and methods: New recombinant, human insulin analogues, coded GKR, GEKR and AKR of the potential long-acting characteristics were evalu-

ated in our institute. In each of the analogue two aminoacid residues were added to C-terminus of B chain (B31Lys- B32Arg). Additional changes referred to B3 and A22 positions. These modifications have resulted in shifting of the isoelectric point to the highest values (6.6–7.0) comparing to human insulin. The study examined single-dose and chronic (21 or 28-day) hypoglycemic action of the new analogues on the hyperglycemic animal model (streptozotocin rats) in comparison to the control group of physiological salt solution (0.9% sodium chloratum). Experimental hyperglycemia was induced by streptozotocin in doses ranging from 32 to 40 mg/kg b.w (mimicked mild to severe form of clinical diabetes). The overall glycemic profiles up to 36 h were evaluated after a single subcutaneous dose of the study preparations. In the multiple-dose experiment preparations were administered 2 or 3 times daily to maintain anticipated glucose levels close to normoglycaemia. Glycemia in steady-state was controlled once-a-day in the morning before the first daily dose of an analogue. Observation was continued and one-daily glycaemia measurement was performed up to 11 days (in case of GKR) and up to 14 days (in case of GEKR and AKR) after stopping the analogues administration. Some safety aspects have also been assessed. Histology observations of skin, subcutaneous tissue and main internal organs were carried out after the termination of pharmacological experiments.

Results: The multiple-dose experiment confirmed with statistical significance hypoglycaemic properties of GEKR, GKR and AKR insulin in comparison to the control group (Newman-Keuls test; $p < 0.05$ in case of each analogue). After stopping each analogue's injection the prolonged hypoglycemic effect was stable and observed up to 11 or 14 days. The concentrations of blood glucose in subsequent days were statistically different than glucose level in the control group ($p < 0.05$ in each case). Means values of glucose concentrations in the subsequent days ranged 126–146, 148–198 and 165–222 mg/dl in case of GKR, GEKR and AKR, respectively. No macroscopic and microscopic pathological changes in the injection site and in all tested organs were found.

Conclusion: The prolonged activity of insulin analogues is supposed to be due to formation of a very stable deposit in the site of administration. Because of the isoelectric point of about 7, solubility of the new insulin analogues decreases in physiological pH and this probably causes their precipitation at the subcutaneous tissue and slow release to the blood thanks to which a therapeutic level may be much longer maintain. The tested insulin are candidates for even less frequent subcutaneous administration than once-a-day.

Duration of diabetes and hypoglycaemia rates in type 2 diabetes patients treated with insulin glargine vs NPH insulin

G. Dailey¹, L. Aurand², S. Garg³

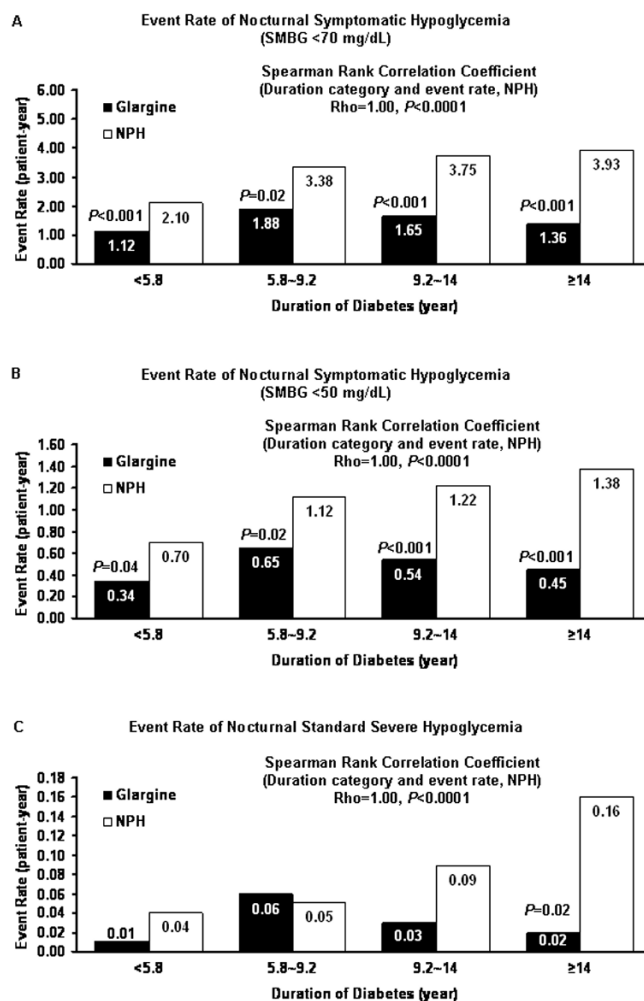

¹Scripps Clinic, La Jolla, ²sanofi-aventis US, Bridgewater, ³University of Colorado, Denver, USA.

Background and aims: Recent ACCORD results suggest the incidence and risk of hypoglycemia increases with duration of type 2 diabetes (T2D). This analysis examined whether there were differences in hypoglycemia rates as a result of T2D duration in patients treated with glargine (GLAR) vs NPH.

Materials and methods: Data were pooled from four 24-wk randomized controlled trials of insulin-naïve T2D patients comparing GLAR + oral antidiabetic drugs (OADs) vs qd NPH+OADs. Patients were stratified into quartiles by T2D duration: <5.8 years (GLAR: n=378; NPH: n=285); 5.8–9.2 years (n=330 and 269, respectively); 9.2–14 years (n=289, 276); and ≥14 years (n=261, 242).

Results: Of 2330 patients, 1258 received GLAR, 1072 NPH. Baseline demographics were similar except T2D duration in the highest quartile (GLAR: 19.64 years, NPH: 18.25 years; $P=0.002$). Despite similar or better HbA_{1c} levels at endpoint for each quartile, GLAR patients had fewer episodes of nocturnal hypoglycemia (SMBG <70 mg/dl) vs NPH ($P < 0.05$ for all). With duration increased, patients on GLAR had less nocturnal hypoglycemia at successively lower blood glucose (BG) cut-offs, eg, patients with T2D for ≥14 years had significantly fewer severe nocturnal hypoglycemic episodes defined as SMBG <50 mg/dl or <36 mg/dl despite a better endpoint HbA_{1c} for patients with ≥14-years T2D duration (7.71% GLAR vs 7.93% NPH; $P=0.031$) with similar insulin dose (mean insulin dose GLAR vs NPH: 33 vs 34 U). Nocturnal hypoglycemia increased significantly only with NPH with increasing T2D duration (for NPH: SMBG <70 mg/dl, <50 mg/dl, and severe hypoglycemia; Rho (Spearman Correlation Coefficient)=1, $P < 0.0001$ [Figure]).

Conclusion: We conclude that with longer T2D duration, patients taking GLAR had significantly less nocturnal hypoglycemia compared with NPH at successively lower BG thresholds.

Clinical predictors of risk of hypoglycaemia during addition and titration of insulin glargine for type 2 diabetes

D.M. Karl¹, J. Gill², R. Zhou³, M.C. Riddle⁴

¹The Endocrine Clinic, Portland, ²sanofi-aventis US, Bridgewater, ³Medpace, Cincinnati, ⁴Oregon Health and Science University, Portland, USA.

Background and aims: Adding and titrating basal insulin can restore HbA_{1c} to target levels for many patients with inadequate control of type 2 diabetes (T2D) with oral agents alone. A leading barrier is hypoglycemia which halts titration and may put patients at risk. Identifying patients with high risk of hypoglycemia might assist in titration and early addition of prandial insulin.

Materials and methods: Seeking clinical predictors of hypoglycemia, we analyzed data for 2251 patients (45% women, mean age 58 years, duration of DM 8.9 years, BMI 31.0 kg/m², taking 0–2 oral agents) in 11 studies with at least 24-week use of insulin glargine in a treat-to-target dosing scheme. Hypoglycemia was systematically identified and classified as symptomatic, confirmed by glucose <50 mg/dL, or severe (3rd party assistance).

Results: The % of patients affected (incidence) was 51.6, 25.4, and 1.5 for symptomatic, confirmed, and severe hypoglycemia, respectively. Mean event-rates/participant-year were 6.46, 1.30, and 0.06, respectively. Values were entered into multivariate statistical models. Model 1 included age, gender, duration of diabetes and oral therapy, BMI, baseline HbA_{1c} and FPG, and use of a sulfonylurea with metformin vs metformin alone. Model 2 added endpoint HbA_{1c}. Incidence of symptomatic hypoglycemia was independently associated with age, duration of diabetes, lower BMI, and use of a sulfonylurea with

metformin vs metformin alone. HbA_{1c} after insulin glargine treatment was also independently associated, with 1/3 increased risk per 1% lower HbA_{1c} . After adjustment for attained HbA_{1c} associations of baseline, predictors with hypoglycemia were equal or increased.

Conclusion: 1) Lower HbA_{1c} after treatment, consistent with intensive titration of dose, increased the risk of hypoglycemia. 2) Independent of attained HbA_{1c} , younger age, longer duration of diabetes, less adiposity, and use of a sulfonylurea with metformin predicted higher risk.

Incidence of Symptomatic Hypoglycemia

Independently associated covariates	Model 1 Baseline Factors		Model 2 Model 1 + Endpoint HbA_{1c}	
	Odds ratio	p-value	Odds ratio	p-value
Age (yr)	0.989	0.0337	0.987	0.0107
Duration of diabetes (yr)	1.015	0.0610	1.021	0.0089
BMI (kg/m^2)	0.962	<0.0001	0.963	0.0001
Metformin vs. metformin + sulfonylurea	0.238	<0.0001	0.209	<0.0001
Endpoint HbA_{1c}	-	-	0.669	<0.0001

Are older patients with type 2 diabetes and insulin therapy under worse glycaemic control?

V. Hartung¹, K. Reise¹, C. Kloos¹, S. Keil¹, A. Kwetkat², T. Lehmann³, G. Wolf¹, U.A. Müller¹

¹Internal Medicine III, University Hospital, ²Geriatrics, University Hospital, ³University Hospital, Jena, Germany.

Background and aims: Poor metabolic control and increased frequency of hypoglycaemia are considered to arise from diminishing competence in personal management and cumulative multimorbidity in elderly patients with insulin therapy. In well-known clinical studies for the treatment of type 2 diabetes mellitus (T2DM) the influence of patients' age is not specifically examined: UKPDS <65y, Kumamoto <70y, ACCORD 62y, ADVANCE 66y, VDAT 60y, 4T 62y. For evaluating these assumptions we investigated the incidence of any hypoglycaemia and clinical characteristics of insulin treated patients with T2DM.

Materials and methods: By assessing the frequency of any hypoglycaemia for the preceding 12 months in 393 insulin treated patients with T2DM aged 41 to 90 years at a university outpatient department we used a standardised questionnaire and interrelated with clinical and laboratory data drawn from the electronic patient record EMIL. Patients were separated on the basis of the median age, 68 years. Non-severe hypoglycaemia was defined as either a condition with symptoms in conjunction with hypoglycaemia and rapid attenuation after carbohydrate ingestion or a plasma glucose test below 2.2 mmol/l without the necessity of showing symptoms. Severe hypoglycaemia was defined as the imperative for an i.v. injection of glucose or a dose of glucagon intramuscular. Each patient had a structured education in the last 20 years. HbA_{1c} was DCCT adjusted.

Results: The patients had a significantly longer period since diagnosis (<68y: 15±7y; ≥68y: 20±9y; $p<0.01$) and a meaningful lower BMI (<68y: 34±6 kg/m^2 ; ≥68y: 32±5 kg/m^2 ; $p<0.01$). Neither did HbA_{1c} differ (<68y: 6.8%; ≥68y: 6.7%), nor the frequency of non severe hypoglycaemia (<68y: 0.29/pat/week; ≥68y: 0.22/pat/week) or of severe hypoglycaemia in the last 12 months (0.03/pat/y; both). The blood glucose threshold for symptoms of hypoglycaemia was also similar (<68y: 3.8 mmol/l; ≥68y: 3.6 mmol/l). Taking non severe hypoglycaemia as dependent variable and adjusting for insulin dose, gender, HbA_{1c} and age, the linear regression analyses revealed significant associations for more frequent severe hypoglycaemia in the last 12 months ($p<0.01$), a longer time since diagnosis ($p<0.01$), a major fear of hypoglycaemia ($p<0.01$) and a lower BMI ($p=0.046$). In linear regression analyses with HbA_{1c} as dependent variable increasing insulin dose ($p<0.01$), a lower incidence of severe hypoglycaemia during the last 12 months ($p<0.01$) and female gender ($p=0.045$) are significantly associated after adjustment time since diagnosis, fear of hypoglycaemia, BMI, non severe hypoglycaemia and age.

Conclusions: Despite extended duration of disease and in contrast to clinical experience, hypoglycaemia did not occur more often in elderly patients with insulin treated T2DM. Furthermore HbA_{1c} has not increased, even though previous studies proved its rising in age even in sound persons. The applica-

bility of these findings for general practitioners' patients or retirement home residents needs to be additionally evaluated.

645

Association between less physical activity level and reports of hypoglycaemia in patients with type 1 diabetes mellitus

C. Kümmel Duarte;

Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Background and aims: Daily practice of physical activity (PA) and exercise are recommended for individual with diabetes mellitus (DM), however, this could predict hypoglycemia. The present study aim to evaluate cross-sectionally the association between PA level and report of hypoglycemia episodes in patients with type 1 DM.

Materials and methods: Outpatients with type 1 DM followed consecutively in Endocrinology Division had PA level assessed by the International PA Questionnaire (long form) and the patients were classified in less, moderate, and the very active. The patients answered questions about self-care related to exercise practice and moderate and/or severe hypoglycemia episodes in the last six months. The Ethical Committee of Hospital de Clínicas approved this protocol.

Results: One hundred and twenty six patients with type 1 DM [35 (28-47) years old; 55% women; HbA_{1c} 9.3 ± 2.1%; BMI 25.0 ± 4.2 kg/m^2] were classified according to PA in less active [$n = 15$ (12%)], moderate active [$n = 81$ (64%)], and very active [$n = 30$ (24%)]. The PA realized at work-related and transport-related PAs were the principal factors to determine the PA level of moderate and very active patients ($P<0.05$; Kuskall-Wallis test). Very active patients presented lower values of plasma glucose (150 ± 80 mg/dL vs. 216 ± 113 mg/dL; $P=0.023$) and LDL-cholesterol (178 ± 49 mg/dL vs. 187 ± 46 mg/dL; $P=0.011$) as compared to less active patients [ANOVA test (LSD post-hoc)]. A smaller proportion of the very active patients (33%) reported moderate and/or severe hypoglycemic episodes in the last six months when compared with less active patients (60%) and moderate active (58%; X^2 test; $P=0.056$). Bigger proportion of moderate active patients (48%) and very active patients (67%) practiced an exercise regularly as compared to the less active patients (13%; X^2 test; $P=0.003$). Considering only the 61 patients who have practiced exercise regularly: 22 patients have received specific advises about self-care and 28 patients realized some care before, during, and after exercise, without difference between the groups (X^2 test). Among the self-care, the food intake was the most cited (25%), followed by diet and capillary glucose monitoring (21%). Regression model was constructed to evaluate the possible association between PA level and report of hypoglycemia episodes (dependent variable). Less active patients presented three times more chance of reported episodes of hypoglycemia when compared with very active patients (OR 3.49; IC 95% 1.26-9.70; $P=0.016$), adjusted for fasting glucose, diet, and exercise practice. Alpha <0.05 (18.0 SPSS version).

Conclusion: Most patients with type 1 DM were classified as active, however due to the work-related and transport-related PAs and not by regularly exercise practice. Few patients have taken self-care about hypoglycemia prevention related with exercise practice. Outpatients with type 1 DM and less active presented more chances of hypoglycemia report, probably by the practice of informal moderate/vigorous PA without specific self-care.

Clinical Trial Registration Number: 08612

The relationship between HbA_{1c} values and the occurrence of hypo- and hyperglycaemia as assessed by continuous glucose monitoring in patients with type 1 diabetes

D. Tsujino, R. Nishimura, C. Kobayashi, K. Taki, K. Andou, A. Morimoto, K. Utsunomiya;

Jikei University School of Medicine, Tokyo, Japan.

Background and aims: To examine the relationship between the occurrence of hypo-/hyperglycaemia and HbA_{1c} values, as assessed by continuous glucose monitoring (CGM) in patients with type 1 diabetes receiving basal-bolus insulin therapy (excluding CSII).

Materials and methods: The study's subjects comprised a total of 71 patients with type 1 diabetes receiving basal-bolus insulin therapy, who were put on a CGMS GOLD (Medtronic, Inc., Northridge, CA) immediately after admission. The subjects were divided into four groups by HbA_{1c} (NGSP value) at

admission: group A, those with HbA1c up to 7%; group B, those with HbA1c > 7% and up to 8%; group C, those with HbA1c > 8% and up to 9%; and group D, those with HbA1c > 9%. The first serial measured values over a 24-hour period in these patients were subjected to analysis, with hypoglycaemia and hyperglycaemia defined as HbA1c 180 mg/dL, respectively, to examine how HbA1c values might be associated with the frequency of hypoglycaemia episodes. Additionally, all groups were compared for 24-hour mean glucose levels and their standard deviations (SDs), duration of hypoglycaemia, duration of nocturnal hypoglycaemia (from 23:00PM to 06:00AM) and duration of hyperglycaemia.

Results: The study's subjects comprised 15 patients in group A, 22 patients in group B; 15 patients in group C; and 19 patients in group D. The median (25–75th percentile) values for the subjects in groups A to D were as follows: age, 37 (33–59), 40 (29–58), 35 (30–43) and 40 (32–58); BMI (kg/m²), 19.6 (17.7–21.5), 21.1 (19.2–23.1), 22.7 (21.2–24.7) and 21.3 (20.2–23.6); urinary CPR (μg/day), 1.4 (0.8–7.2), 1.1 (0.5–6.4), 1.1 (0.6–2.7) and 1.3 (0.6–10.3). Of the variables, only BMI was significantly different between the groups ($P = 0.012$; Kruskal–Wallis test). CGM data obtained over a 24-hour period in groups A to D were as follows: 24-hour mean glucose level (mg/dL), 134 (111–156), 153 (122–178), 168 (149–200) and 180 (138–208); SD of the mean glucose level, 61 (40–70), 55 (47–65), 63 (46–67) and 59 (46–80); duration of hypoglycaemia (min), 175 (80–350), 100 (0–260), 50 (0–105) and 70 (0–255); duration of nocturnal hypoglycaemia (min), 130 (45–280), 35 (0–155), 0 (0–106) and 0 (0–110); and duration of hyperglycaemia (min), 355 (110–595), 400 (213–624), 540 (395–860) and 520 (350–910), respectively. A comparison between the groups showed that significantly shorter hypoglycaemia duration was seen in group C than in group A ($P = 0.015$; Mann–Whitney test); and that hyperglycaemia occupied significantly longer in group C than in groups A and B ($P = 0.042$, $P = 0.038$, respectively; Mann–Whitney test). Bimodal logistic regression analyses with independent variables defined as age, BMI, urinary CPR, HbA1c values and SDs demonstrated that the presence or absence of hypoglycaemic episodes and nocturnal hypoglycaemic episodes alone were significantly correlated with HbA1c values, with the odds ratio for hypoglycaemia being 0.584 ($P = 0.008$) and the odds ratio for nocturnal hypoglycaemia being 0.646 ($P = 0.021$).

Conclusion: Of the type 1 diabetic patients stratified by HbA1c values, duration of hypoglycaemia in those with HbA1c > 8% and up to 9% were significantly shorter than those with HbA1c up to 7%. It was also shown that an increase in HbA1c values of 1% was associated with a 42% reduction in the relative risk for hypoglycaemia and a 35% reduction in the relative risk for nocturnal hypoglycaemia.

647

Factors associated with hypoglycaemic blood glucose levels two hours after a 75g oral glucose load: Does stature matter? The DEPLAN study
S. Liatis¹, E. Diakoumopoulou¹, M. Dandoulakis², D. Perrea¹, N.

Katsilambros¹, K. Makrilakis¹;

¹1st Internal Medicine Department & Diabetes Center, Athens University Medical School Laiko Hospital, ²Health Center of Vari, Athens, Greece.

Background and aims: The observation of low plasma glucose levels, often within the hypoglycemic range, is a common phenomenon during an oral glucose tolerance test (OGTT). Although the upper limits of normal for OGTT are well-standardized, the significance of low glucose values obtained during testing and their relation to body size is less clear. Short height has been related to increased incidence of impaired glucose tolerance, especially in women. Aim of the present study was to investigate possible anthropometric and clinical factors associated with the occurrence of low blood glucose levels (≤ 70 mg/dL) after an OGTT.

Materials and methods: The study participants were generally healthy individuals who underwent an OGTT during a screening procedure for participation in a type 2 diabetes prevention program by lifestyle modification (the DEPLAN study). Hypoglycemia was defined as a plasma glucose value ≤ 70 mg/dL (3.89mmol/L). Only individuals with normal glucose tolerance status were included in the present analysis. A subgroup of the participants underwent a second OGTT, after three years of follow-up.

Results: Out of 577 individuals (242 [41.94%] males, aged 54.37 [53.52–55.21] years) included in the present analysis, 108 (18.71%) had a hypoglycemic 2-hour post-load glucose value. These individuals, compared to those without 2-hour hypoglycemia (and normal glucose tolerance), were males in a higher proportion (66 [61.11%], OR: 2.62 [1.70–4.02], $P < 0.001$), they were younger (52.41 [50.80–54.01] vs. 54.81 [53.84–55.79] years, $P = 0.01$) had lower BMI (27.75 [27.00–28.49] vs. 29.07 [28.62–29.52] Kg/m², $P = 0.03$), lower

fasting plasma glucose (91.43 [89.82–93.03] vs. 94.61 [93.85–95.35] mg/dL, $P < 0.001$) and higher stature (1.72 [1.70–1.73] vs. 1.66 [1.65–1.67], $P < 0.001$). There was no difference between the two groups in terms of blood pressure, waist circumference, physical activity and family history of diabetes. In multivariable analysis (logistic regression), higher stature (OR: 1.08 per 1cm increase [1.05–1.11], $P < 0.001$) and lower fasting plasma glucose (OR: 1.48 per 10mg decrease [0.95–2.06], $P = 0.001$) were independent predictors of 2-hour post-load hypoglycemia occurrence. Gender differences disappeared after the introduction of height in the model.

Conclusion: High stature predicts independently hypoglycemic plasma glucose levels 2 hours after an OGTT. The reason is not clear, although it may be hypothesized that taller persons have more muscle tissue for uptake of a fixed (75g) amount of glucose.

PS 045 Risks and costs of hypoglycaemia

648

Incidence and costs of severe hypoglycaemia in diabetes requiring attendance by the emergency service in the United Kingdom

A.J. Farmer¹, K.J. Brockbank², M.L. Keech³, E.J. England⁴, C. Deakin⁴;
¹Department of Primary Health Care, University of Oxford, ²Brockbank Plaut Consulting Limited, Wickford, ³Pharmakos Limited, St Albans, ⁴South Central Ambulance Service NHS Trust, Otterbourne, UK.

Background and aims: Symptomatic hypoglycaemia is an important adverse effect of therapy for diabetes. We determined the incidence of severe hypoglycaemia in a defined population, its management, and the costs associated with requests for emergency assistance from the ambulance service.

Materials and methods: Over a twelve-month period, December 2009 to November 2010, sequential, routinely collected datasets were analysed to measure the incidence of severe hypoglycaemia, defined as requiring emergency assistance from the South Central Ambulance Service NHS Trust. The Trust serves a population of four million people in the south of England, United Kingdom (UK) within which there are estimated to be 161,000 people diagnosed with diabetes over the age of 17 years. Numbers of episodes, management and use of hospital services were identified for calls to those aged >1 year. Costs of accident and emergency department attendance and primary care follow up were estimated using Personal Social Services Research Unit costs 2010. Costs of emergency call, attendance at the scene and conveyance to hospital were provided by the ambulance trust

Results: During the survey period, 398,409 emergency calls were received, of which 4081 (1.02%) were recorded with hypoglycaemia as the 'chief complaint'. 53.8% (2108) of calls related to men, with the age distribution of patients and the number of emergency calls for hypoglycaemia by age group (years) shown in the table. The incidence of hypoglycaemia was 39/100,000 population for ages 1 to 39 years, and 163/100,000 for those aged 40 years and above. At least one blood glucose measurement was recorded in 83.4% of calls and, where recorded, the initial median (IQR) glucose level was 2.3 (1.7) mmol/l. 65.7% of those attended were given carbohydrates, oral or intravenous glucose, or glucagon. 1441 (35.3%) of those attended were taken to hospital. The estimated total cost (£'000s) of initial ambulance attendance and treatment at scene was £909; if transport to hospital was necessary, the additional ambulance transport costs were £223 plus emergency department costs of £140; and the cost of primary care follow-up was estimated as a further £0.62. The average cost per emergency call was £326.

Conclusion: This is the largest UK survey to describe the incidence of severe hypoglycaemia requiring an emergency ambulance attendance, with an estimated annual cost of £16.9 million for England. The highest numbers of incidents involving hypoglycaemia are in older age groups. Despite overall improvements in glycaemic control, there remains a substantial burden from hypoglycaemia.

Emergency calls for hypoglycaemia by age group (years)

Age Group	Number of calls for patients in age group	Percentage of all calls
1 to 19	207	5.1
20-39	591	14.5
40-59	1083	26.6
60-79	1330	32.7
≥80	862	21.2

Comparison of hypoglycaemia risk and cost between oral antidiabetic monotherapies in elderly patients with type 2 diabetes mellitus in a U.S. population

H. Yang¹, M. Marynchenko¹, M. Bron², E. Wu¹, A.P. Yu¹;

¹Analysis Group, Inc., Boston, ²Takeda Pharmaceuticals International, Inc., Deerfield, USA.

Background and aims: The objectives of the study were to assess the risks and annual healthcare costs of hypoglycemia associated with oral antidiabetic drug (OAD) monotherapy types in the elderly.

Materials and methods: We conducted a retrospective analysis of the IH-CIS/Ingenix impact claims database from January 1999 to September 2008. Patients aged ≥65 years with at least two claims for T2DM diagnosis who received monotherapy with an OAD (sulfonylurea [SU], metformin [MET], or thiazolidinedione [TZD]) were followed for 1 year from the OAD initiation date. DPP4 and meglitinide are not included in the analysis due to small sample sizes. Hypoglycemia was identified using ICD-9 codes of 250.8X, 251.0X, 251.1X, or 251.2X. Rates of hypoglycemia were estimated for each OAD class. Risk of hypoglycemia associated with each OAD in reference to SU monotherapy was examined using a Cox proportional hazard regression model adjusting for patient characteristics and comorbidities. Healthcare costs in the 12 months following the initiation of the OAD were compared descriptively between patients with at least one hypoglycemia event and patients without hypoglycemia using Wilcoxon tests.

Results: The sample included 7,620 SU patients, 6,675 MET patients, and 1,940 TZD patients. The rates of hypoglycemia associated with SU, MET, and TZD at 1 year were 2.7%, 1.5%, and 1.3%, respectively. Both MET and TZD carried a lower risk of hypoglycemia than SU (hazard ratios of 0.63 and 0.49, respectively, $p < 0.001$). Total and diabetes-related healthcare costs were higher in patients with than without hypoglycemia for each OAD (except for total costs in the TZD group; Table).

Conclusion: Among OAD monotherapies, SU poses the highest risk of hypoglycemic events in elderly T2DM patients. Hypoglycemia in all OAD classes is associated with increased healthcare costs.

Descriptive Annual Healthcare Costs

Annual Healthcare Costs (US Dollars, mean±SD)	SU			MET			TZD		
	Hypo-glycemia (N=208)	No Hypo-glycemia (N=7,412)	P	Hypo-glycemia (N=102)	No Hypo-glycemia (N=6,573)	P	Hypo-glycemia (N=26)	No Hypo-glycemia (N=1,914)	P
Total	27,100±36,500	11,460±22,102	<.001	23,620±46,090	9,880±15,656	<.001	18,169±20,268	13,641±26,233	0.183
Diabetes-related	13,834±25,796	3,665±11,710	<.001	11,958±42,141	2,985±8,926	<.001	7,345±11,604	4,216±13,645	0.008

The impact of glucose variability on achievement of glycaemic control and risk of hypoglycaemia in patients with type 2 diabetes

S.E. Inzucchi¹, A. DiGenio², R. Zhou³, G. Umpierrez⁴;

¹Endocrinology, Yale University School of Medicine, New Haven, ²sanofi-aventis US, Bridgewater, ³Medpace, Cincinnati, ⁴Emory University School of Medicine, Atlanta, USA.

Background and aims: Glucose variability has been proposed as a predictor of clinical outcomes in patients with type 2 diabetes (T2D). The impact of glucose variability on glycemic control and hypoglycemia during treatment intensification is unknown.

Materials and methods: We pooled data from 6 randomized controlled clinical trials of insulin glargine (GLAR) vs a comparator (oral agents/other insulins) to determine changes in glucose variability during a treat-to-target (FPG ≤100mg/dL) protocol and to explore the relationships among baseline glucose variability, age, A_{1c}, and hypoglycemia. Glucose variability was calculated from 7-point glucose profiles using standard deviation (SD) and mean amplitude of glycemic excursions (MAGE).

Results: Complete data were available at baseline and 24 weeks for 1699 patients (1026 GLAR, 673 comparator); 43% female, 95% white, mean age 59(9) years and duration of T2D 9(6) years. Mean A1C was reduced from

8.7(.95)% to 7.0(.91)% and FPG from 194(48)mg/dL to 125(38)mg/dL. Glucose variability was significantly reduced on trial in the entire cohort irrespective of treatment type (Table); younger patients (<65 years) experienced twice the reduction of older patients. Patients who failed to achieve A1C $\leq 7.0\%$ had modestly higher baseline glucose variability than those who reached goal. Patients who experienced ≥ 1 symptomatic hypoglycemic event during the study had modestly higher baseline glucose variability than those with no hypoglycemia. Comparable associations of glucose variability, A1C, and hypoglycemia were observed when GLAR patients were analyzed separately.

Conclusion: Our post-hoc analysis shows a significant decrease in glucose variability during therapy with a variety of antihyperglycemic agents, including insulin glargine, and suggests that T2D patients with elevated glucose variability at baseline are at increased risk for hypoglycemic events and greater likelihood of failing to reach A1C $\leq 7.0\%$. Improved understanding of these relationships may lead to better treatment strategies for T2D.

Glucose Variability			
All patients (N=1699)	Change from baseline, mean (SD)		P value
SD	-4.21 (20.2)		<0.001
MAGE	-7.44 (33.2)		<0.001
Relationship of Baseline GV & A1C at 24 Weeks			
	Baseline GV, mean (SD)		LS means* for difference (P value)
All patients (N=1699)	A1C ≤7.0% (N=949)	A1C >7.0% (n=750)	
SD	42.4 (16.8)	44.3 (18.6)	-2.74 (P<0.001)
MAGE	61.7 (27.0)	64.9 (31.1)	-4.57 (P<0.001)
Relationship of Baseline GV & On-Trial Hypoglycemia			
	Baseline GV, mean (SD)		LS means* for difference (P value)
All patients (N=1699)	≥1 hypo event (n=1035)	No hypo (n=663)	
SD	45.8 (18.2)	39.2 (15.8)	4.36 (P<0.001)

Hypoglycaemia in adult vs. elderly type 2 diabetes mellitus patients: risks, costs, and impact on treatment persistence in a U.S. population

M. Bron¹, M. Marynchenko², H. Yang², Y. Yang¹, E. Wu², A.P. Yu²;

¹Global Health Economics and Outcomes Research, Takeda Pharmaceuticals International, Inc., Deerfield, ²Analysis Group, Inc., Boston, USA.

Background and aims: We compared risks of hypoglycemia associated with various antidiabetic drugs, impact on treatment persistence, and estimated healthcare costs between adult and elderly patients with type 2 diabetes mellitus (T2DM).

Materials and methods: A retrospective analysis of the IHCIS/Ingenix impact claims database from 1/1999 to 9/2008 was conducted in T2DM patients aged ≥ 18 yr with ≥ 1 prescription drug claim for an oral antidiabetic (OAD) and a subgroup of elderly patients aged ≥ 65 yr. Hypoglycemia was identified by ICD-9 codes (ICD-9: 250.8X, 251.0X, 251.1X, or 251.2X). Relative hypoglycemia risks of various drug classes were determined using a treatment- and covariate-adjusted Cox proportional hazard regression model with time-varying covariates measured in 6-month intervals. The impact of hypoglycemia on treatment discontinuation (≥ 30 day gap) was evaluated using adjusted generalized estimating equations. Annual healthcare costs following OAD initiation were compared between patients with and without hypoglycemia using adjusted generalized linear models.

Results: Of 207,748 T2DM patients identified, 30,335 were elderly (≥ 65 years). The hazard ratios for hypoglycemia risk associated with sulfonylureas, metformin and thiazolidinediones were 1.95 ($p<0.0001$), 1.08 ($p=0.0843$), and 1.22 ($p<0.0001$), respectively, in the elderly, and 1.56, 1.18, and 1.09 (all $p<0.0001$), respectively, in all adults, including the elderly. The odds of treatment discontinuation for those with vs. without hypoglycemia in a given 6-month interval were greater in elderly (OR=1.35, $p<0.0001$) than in all adults (OR=1.26, $p<0.0001$). The differences in both all-cause and diabetes-related annual healthcare costs between patients with and without hypoglycemia were greater in elderly (all cause: 20,264 US Dollars [USD] vs. USD 11,897; diabetes-related: USD 11,829 vs. USD 4,190, $p<0.0001$) than adult patients (USD 14,031 vs. USD 9,007 and USD 7,012 vs. USD 3,265, respectively, $p<0.0001$).

Conclusion: Compared to adults, elderly T2DM patients exhibit higher risks of treatment-associated hypoglycemia in most treatment groups. Risk of treatment discontinuation and healthcare costs attributable to hypoglycemia are also higher in the elderly.

652

Hypoglycaemia as a risk factor for mortality

A. Shazli, E. Jude, S. Anderson;

Tameside General Hospital, Ashton under Lyne, UK.

Background and aims: Hypoglycaemia (blood glucose <4mmol/l) has been shown to be associated with increased mortality and adverse outcomes in patients admitted with pneumonia, critically ill ICU patients and acute myocardial infarction. The aim was to identify whether hypoglycaemia was a risk factor for mortality in patients admitted to the medical assessment unit (MAU) with medical emergencies.

Materials and methods: Retrospective analysis of all patients who attended the MAU and had blood tests from July 2008 till December 2008 through the laboratory data-base. Patients who had documented hypoglycaemia (n=94; 25 with diabetes) were identified. Information gathered through reviewing individual notes to look at the required parameters. We selected 91 age and sex matched controls (n=11 with diabetes) with blood glucose between 4-7mmol/l.

Results: Patients with hypoglycaemia had lower glucose levels [3.4(95% confidence interval(CI):3.3,3.5) vs 5.8(5.7,5.9)mmol/l]. Median follow-up was 1.14 years during which 54 deaths (44.6% in those with hypoglycaemia vs.13.2%, $X^2=24.8$, $P<0.0001$) occurred. Crude mortality rates were 62.6 deaths per 100 person-years in those with hypoglycaemia at admission, compared with 11.7 deaths per 100 person-years in controls. Cases had higher admission levels of creatinine and urea [171(141, 201) vs.100(70,130) and 11.9(10.1,13.8 vs. 6.9(5.1, 8.8)mmol/l] respectively. Hypoglycaemia [Hazard ratio (HR) = 4.58(2.4,8.7), $P<0.0001$], elevated urea [HR:1.07 (1.05,1.09) per 1mmol increase], creatinine [(HR:1.02,(1.01,1.03) per 10mmol/l], potassium [HR:1.83(1.35,2.49)] and sodium levels [HR: 1.05(1.00, 1.10)] were associated with higher rates of mortality in univariate Cox regression analyses. In multivariate models, age, hypoglycaemia (HR: 4.86(95%CI:2.39,9.86) and urea (HR:1.05(1.02,1.08), independently predicted mortality in acutely ill patients.

Conclusion: In-hospital hypoglycaemia is an important risk factor for mortality and these patients need intensive monitoring and treatment. Larger studies are required to confirm these results.

653

Underestimated impact of non-severe nocturnal hypoglycaemic events (NHEs) on patients' functioning and well being

M. Brod¹, N. Kragh², T.E. Christensen², A.K. Busk²;

¹The Brod Group, Mill Valley, USA, ²Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Although non-severe nocturnal hypoglycaemic events, or NHEs, occur fairly frequently in both children and adults, there is a relative lack of literature on the impact of these events on the lives of patients. We used three sources of data in an attempt to assess the impact of non-severe NHEs.

Materials and methods: Our data sources included a systematic literature review using multiple databases of English articles from 1995-2010; qualitative data from 70 patients in focus groups in three countries; and a four-country survey, which was quantitatively analysed for subjects who had experienced a non-severe NHE in the past month.

Results: We identified 32 relevant articles from the literature search (out of a total of 746) which suggested NHEs impact patients' sleep quality, leading to increased fatigue levels and decreased cognitive ability the following day. This was shown to result in increased absenteeism from work and missed appointments. The focus groups revealed that, irrespective of country, NHEs resulted in reduced sleep quality and next-day functioning, and increased concern over their health, particularly with regards to the status of their diabetes. Data obtained from the survey revealed that 70% of the 2,600 respondents reported experiencing a non-severe NHE during the previous month. 54% of these 1,844 patients were in the workforce. 22.7% of these reported that they were either late or missed a full day of work the following day, resulting in an average of 14.7 hours lost due to absenteeism. 31.8% reported that they missed a meeting or work appointment or did not finish a work task on time. Across all

the data obtained, an average of 20% of those who experienced a non-severe NHE contacted a healthcare professional. Of particular concern was the finding that 20% reduced their insulin dose over subsequent days as a result of the event, with clear implications for the management of their diabetes condition. Non-severe NHEs therefore result in lost work productivity and absenteeism, and a change in patient adherence to treatment regimens.

Conclusion: It is clear that the impact of non-severe NHEs is of some significance and it is therefore of some concern that it has been underestimated and underrepresented in the literature. The results of this study demonstrate that greater focus should now fall on this phenomenon, both clinically and in research, in order to ensure that the lives of those affected can be improved.

Frequency of severe and non severe hypoglycaemia and difficulties at workplace in patients with insulin treated diabetes mellitus

K. Reise¹, V. Hartung¹, T. Lehmann², C. Kloos¹, N. Müller¹, G. Wolf¹, U.A. Müller¹;

¹Internal Medicine III, ²University Hospital, Jena, Germany.

Background and aims: Hypoglycaemia can lead to impairment and thus could become a threat for the patient himself and for others and can result in difficulties at workplace. Starting insulin therapy may have considerable consequences for drivers or policemen. Therefore some patients with type 2 diabetes refuse insulin therapy and accept hyperglycaemic state with all the risks that go along with it. Current occupational medicine guidelines rely on high prevalence data of hypoglycaemia with 10% of insulin treated patients experiencing at least one severe hypoglycaemia per year and 2-3 events of non severe hypoglycaemia per week. We examined the incidence of severe and non-severe hypoglycaemia in employed patients with diabetes mellitus type 1 (DM1) and 2 (DM2) in Germany to verify if these data are still applicable.

Materials and methods: We assessed any hypoglycaemia in 166 insulin treated patients who are still under employment using a standardised questionnaire at a university outpatient department: 105 patients with DM1 (age 42±11years; diabetes duration 17±12years; BMI 26±5kg/m²; HbA1c 7.0±0.8%), 61 patients with DM2 (age 54±7years; time since diagnosis 12±8years; BMI 33±5kg/m²; HbA1c 6.8±1.0%). All patients had at least one structured education in the last 20 years. Non-severe hypoglycaemia was defined as a condition with symptoms consistent with hypoglycaemia and rapid attenuation after carbohydrate ingestion or a plasma glucose test below 2.2mmol/l even without any symptoms. Severe hypoglycaemia was defined as the necessity for injection of glucose i.v. or glucagon intramuscular. We used a Likert scale from 1 to 6 to judge difficulties at workplace (1: no difficulties; 6: great difficulties). The patients were grouped to no difficulties at workplace (score 1-3) and difficulties at workplace (score 4-6). Clinical and laboratory data are drawn from the electronic patient record EMIL (<http://www.itc-ms.de>). HbA1c was DCCT adjusted.

Results: At least one non-severe hypoglycaemia quarterly occurred in 93% of DM1 and in 43% of DM2. The median frequency per week for all patients was 1.15 (max. 10) in DM1; 0.06 (max. 2.5) in DM2 ($p<0.01$) and the mean frequency per week for those who had at least quarterly hypoglycaemia was 1.89 in DM1; 0.56 in DM2; ($p<0.01$), respectively. Severe hypoglycaemia during the last 12 months occurred in 8% DM1 (0.1/pat/y) but no in DM2 ($p<0.05$). Severe hypoglycaemia occurred in 32% DM1 and 3% DM2 since time of diagnosis. Patients state having difficulties at workplace equally frequent, regardless of DM1 or DM2 (15%; 19%; $p<0.58$). In the ordinal regression analyses only frequency of non severe hypoglycaemia was significantly associated with difficulties at workplace ($p=0.02$). With each non severe hypoglycaemia per week difficulties-at-work-score increased by 0.2 after adjustment for severe hypoglycaemia in the last 12 months, HbA1c, age and diabetes duration.

Conclusion: Frequency of hypoglycaemia in employed patients with diabetes is lower than given in current occupational medicine guidelines. Especially for type 2 diabetes the occurrence of hypoglycaemia is overestimated. Furthermore difficulties at workplace seem more to be the result of an increased frequency of non severe hypoglycaemia and are not so much dependent on severe ones.

Absence of caspase-1 protects against diet-induced obesity and insulin resistance: identification of underlying mechanisms

R. Stienstra^{1,2}, J.A. van Diepen³, C.J. Tack¹, P.C.N. Rensen³, L.A.B. Joosten¹, M.G. Netea¹, T. Devi-Kanneganti²;

¹General Internal Medicine, Nijmegen, Netherlands, ²St Jude Children's Research Hospital, Memphis, USA, ³Leiden University Medical Centre, Netherlands.

Background and aims: The world-wide epidemic of obesity has accelerated the number of individuals diagnosed with type 2 diabetes. Obesity is characterized by an enlargement of adipose tissue mass that promotes the development of a chronic low grade inflammation. Obesity-induced inflammation leads to enhanced production of numerous pro-inflammatory mediators including IL-18 and IL-1 β that may cause insulin resistance. In order to become active, both IL-18 and IL-1 β are processed by the cysteine protease caspase-1. Previously, we have shown that caspase-1 is activated in adipose tissue of obese animals. Therefore, the aim of this study was to test whether caspase-1 contributes to the development of obesity and insulin resistance and to identify possible underlying mechanisms.

Materials and methods: Both wild-type (Wt) and Caspase-1 $^{-/-}$ animals were fed a high fat diet to induce obesity. Metabolic cage studies, hyperinsulinemic-euglycemic clamps and mechanistic studies on triglyceride (TG) metabolism were performed.

Results: Caspase-1 $^{-/-}$ animals were protected against the development of high fat diet induced obesity. Despite a similar caloric intake (Wt: 11.99 \pm 0.42, Caspase-1 $^{-/-}$: 12.22 \pm 0.53 (kcal/day), ns), HFD-feeding of wild-type mice led to higher plasma insulin (Wt: 6894 \pm 760, Casp-1 $^{-/-}$: 3848 \pm 575 (pg/ml), p -value < 0.001), leptin (Wt: 79684 \pm 11246, Casp-1 $^{-/-}$: 33703 \pm 5629 (pg/ml), p -value < 0.001) and resistin levels (Wt: 5425 \pm 295, Casp-1 $^{-/-}$: 3305 \pm 338 (pg/ml), p -value < 0.01) as compared to Caspase-1 $^{-/-}$ animals. Importantly, Caspase-1 $^{-/-}$ animals were resistant to the development of insulin resistance. Protection against obesity was not caused by a decrease in intestinal TG uptake in Caspase-1 $^{-/-}$ animals, as assessed by gavage of glycerol tri[³H] oleate-labeled olive oil after Triton WR1339 injection. However, oil red O staining of the intestine revealed numerous lipid droplets within the enterocytes of Caspase-1 $^{-/-}$ animals compared to wild-type mice suggestive of abnormal lipid processing. In addition, VLDL-TG production was decreased by -49% ($P<0.01$) in the absence of Caspase-1 together with an impairment in VLDL-TG clearance. Finally, metabolic cage studies revealed an enhancement in total energy expenditure in Caspase-1 $^{-/-}$ animals.

Conclusion: Absence of Caspase-1 protects against the development of diet-induced obesity that may partly be mediated through effects on energy expenditure and a reduced flux of triglycerides from the intestine and liver towards adipose tissue. Inhibition of Caspase-1 may be a useful therapeutic strategy for treatment of obesity.

Role of MAPK38 and MKK3/6 in the diabetes development

Á. Verdugo^{1,2}, B. González¹, Á. González-Rodríguez^{3,4}, Á.M. Valverde^{3,4}, R.J. Davis⁵, A. Cuenda², G. Sabio¹;

¹Vascular Biology and Inflammation, Centro Nacional de Investigaciones Cardiovasculares (CNIC), ²Immunology and Oncology, Centro Nacional de Biotecnología, Consejo Superior de Investigaciones Científicas, ³Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas Asociadas. Instituto de Salud Carlos III, ⁴Instituto de Investigaciones Biomédicas Alberto Sols (Centro Mixto CSIC/UAM), Madrid, Spain, ⁵Howard Hughes Medical Institute and Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, USA.

Background and aims: The obesity and diabetes are associated with increased intracellular p38 mitogen-activated protein kinase (MAPK) signaling, which may promote tissue inflammation and injury. The family members of p38 MAPK are proteins that regulate different and important process like proliferation and apoptosis. These kinases are activated for a double phosphorylation on serine and threonine for MKK3 and MKK6. There are four p38MAPK isoform with different roles in the signaling, p38 α , β , γ and δ . While p38 α and β are the most well known, p38 γ and p38 δ still less understood. In

fact, the p38 α has been implicated in the development of insulin resistance and p38 δ in the production and release of insulin and in the development of obesity-induced pancreatitis. On the other hand, MKK3, the upstream kinase was described that has an important role of declining renal function in diabetic mice, and the other upstream kinase, MKK6 inhibited IRS-1 and IRS-2 expression in adipocytes. The objective of our study is to investigate the role of these kinases in the control of obesity-induced insulin resistance using genetic modified mice

Materials and methods: Mice lacking p38 δ/γ or MKK3-/- MKK6-/+ and WT control mice were fed with high fat diet (HFD) or chow diet for 16 weeks in order to produce obesity-induced diabetes. Body weight, glucose, insulin, and insulin resistance in serum and tissues were analyzed.

Results: After 16 weeks fed with HFD, MKK3-/- MKK6-/+ and p38 δ/γ mice were leaner than WT mice. Analysis of glucose levels in the blood also indicates that MKK3-/-MKK6-/+ and p38 δ/γ develop less glucose intolerance after the HFD.

Conclusion: Lack of the expression of MKK3 and MKK6 results in leaner mice than WT mice after HFD. This could be due to a reduction on the activation of p38 δ/γ by these kinases. In fact, the mice lacking p38 δ/γ have the same reduction on body weight after the diet, indicating that MKK3 and MKK6 exert their action in controlling obesity, at least part, through the activation of p38 δ/γ

Periportal μ -opioid receptors regulate a neural gut-brain cross-talk between intestinal gluconeogenesis and hypothalamus, controlling energy and glucose homeostasis

G. Mithieux, C. Duraffourd, A. Gautier-Stein, F. De Vadder, F. Delaere, A. Penhoat, B. Brusset;
Inserm u.855, Lyon, France.

Background and aims: Intestinal gluconeogenesis is a recently described function of control of energy and glucose homeostasis. Glucose produced by the intestine is detected by a portal glucose sensor and activates hypothalamic targets, the signal being transmitted by neural afferents. This may account for the decreased food intake and increased insulin sensitivity observed in protein-fed rats. A number of peptides issued from the partial digestion of proteins have μ -opioid activity (agonists increase food intake and antagonists decrease it). Moreover, μ -opioid receptors (MOR) are widely expressed in the gut. We investigated if MOR modulators could induce their effect via a modulation of intestinal gluconeogenesis.

Materials and methods: Portal infusions of μ -opioid receptor agonists or antagonists were performed for 8 hours in conscious rats fed on normal chow or high-protein diet. Glc6Pase and PEPCK proteins (regulatory enzymes of gluconeogenesis) were quantified as an estimate of gut gluconeogenesis. Comparable experiments were performed with both wild type and MOR-knockout mice. The presence of MOR within portal vein walls (by immunofluorescence) and the impact of infusions on the dorsal vagal complex and hypothalamus (by c-Fos immunohistochemistry) were studied.

Results: On chow diet, Glc6Pase activity was lowered in rats infused with a MOR agonist (4.0 \pm 1.4 U/g of protein for DAMGO vs 9.7 \pm 0.9 U/g of protein for control saline infusion; $P < 0.05$), whereas it was increased in rats infused with a MOR antagonist (17.7 \pm 0.3 U/g for Naloxone, $P < 0.05$ vs saline). These results were correlated with Glc6Pase and PEPCK protein amounts. High-protein diet induced Glc6Pase activity in the intestine vs chow diet (25.4 \pm 2.9 U/g of protein vs chow diet with saline infusion; $P < 0.05$). No differences were found upon antagonist infusion on Glc6Pase activity in high-protein fed rats (24.1 \pm 2.1 U/g of protein for Naloxone infusion, NS vs saline). However, the inhibition by MOR agonist was still occurring (13.1 \pm 1.4 U/g of protein; $P < 0.05$ vs saline infusion). These results were correlated with PEPCK expression. The effects produced by either MOR agonists or antagonists were abolished after portal denervation by capsaicin, suggesting that a central relay involving portal afferents was required to the control of intestinal gluconeogenesis. Immunohistochemistry showed that MOR were tightly co-localized with neurofilaments flanking the portal vein. The number of c-Fos positive cells was 2 to 3 times higher in the Nucleus of the Solitary Tract, the Area Postrema and hypothalamic nuclei of rats infused with MOR-antagonists. The c-Fos increase was abolished everywhere after portal denervation. Proteolytic digests or selected di- or tri-peptides increased Glc6Pase and PEPCK, as did MOR antagonists, in either rats or wild type mice. None of these effects was observed in MOR-KO mice. Finally, MOR-KO mice were

insensitive to the satiety and insulin-sensitization induced by a protein-enriched diet, such as occurring in WT mice.

Conclusion: 1) MOR in the periportal area may initiate a neural circuit of control of intestinal gluconeogenesis having an impact on energy and glucose homeostasis, in addition to their well-known central action on food intake via the reward system; 2) the satiety and insulin-sensitizing effects of protein-enriched diet may be dependent on an antagonistic action on intestinal MOR via their proteolytic digests.

MIF deficient mice have improved insulin sensitivity and adipose tissue inflammation following high-fat diet

O. Finucane^{1,2}, C.M. Reynolds², F.C. McGillicuddy², K.A. Harford², H.M. Roche²;

¹Institute of Molecular Medicine, Trinity College Dublin, ²Nutrigenomics Research Group, UCD, Conway Institute, Dublin, Ireland.

Background and aims: Adipose tissue inflammation is positively correlated with obesity, insulin resistance (IR) and Type 2 Diabetes. Macrophage Migration inhibitory factor (MIF) is a pro-inflammatory mediator that promotes cytokine secretion and amplifies transmigration, recruitment and activation of leukocytes and is elevated during obesity. Little however is known about the contribution of MIF in development of high-fat diet (HFD) induced obesity and IR. In this study we hypothesize that mice lacking MIF protein will be protected from the adverse effects of high fat diet (HFD) on insulin sensitivity.

Materials and methods: Wildtype(WT) and MIF^{-/-} mice were placed on a HFD (45% palm oil) for 16 weeks. Body weight and food intake was monitored weekly. Insulin sensitivity was assessed at baseline and after high-fat feeding by performing insulin (0.75U/kg insulin) and glucose (1.5g/kg glucose) tolerance tests. Stromal vascular fraction (SVF) isolated from epididymal adipose tissue was stained with antibodies against F4/80, CD11b, and CD11c to identify the number and type of macrophage present and analysed by flow cytometry. SVF cells triple positive (F4/80⁺/CD11b⁺/CD11c⁺) were classified as M1-proinflammatory macrophages and cells double positive (F4/80⁺/CD11b⁺/CD11c⁻) were classified as M2-antiinflammatory macrophages. Cytokine secretion from adipose tissue explants (50mg/1ml media) cultured for 24hours was quantified by Mesoscale multiplex ELISA.

Results: Despite similar food intake MIF^{-/-} mice gain significantly less weight (7g weight difference) than WT mice when fed HFD. MIF^{-/-} mice displayed greater insulin sensitivity and glucose tolerance compared with WT after HFD. M1/M2 macrophage infiltration into adipose tissue was significantly lower in MIF^{-/-} mice compared to WT mice (M1:17.12 \pm 5%;29.93 \pm 5%) (M2:0.861 \pm 0.038%;1.47 \pm 0.038%). Cytokine secretion from adipose tissue explants increased with HFD in WT, but not in MIF^{-/-} mice. The most prominent difference observed was on IL-6 secretion. Weight matched animals displayed identical results.

Conclusion: Observed weight differences suggest MIF plays a key role in energy metabolism. We controlled for weight to identify the specific contribution of MIF on IR and adipose tissue inflammation. Our study supported our hypothesis and demonstrated that lack of MIF protects from diet-induced IR by attenuating macrophage infiltration and reducing adipose tissue inflammation. MIF may serve as a potential biomarker for disease progression or therapeutic target for the treatment of obesity induced IR and Type 2 Diabetes.

Analysis of TBC1D1 in glucose- and fatty acid-metabolism in an obese mouse model

J. Dokas¹, A. Chadt¹, F. Neumann¹, H.-G. Joost¹, H. Al-Hasani^{1,2};

¹Department of Pharmacology, German Institute of Human Nutrition, Potsdam-Rehbruecke, Nuthetal, ²Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Heinrich-Heine-University, Duesseldorf, Germany.

Background and aims: TBC1D1 is a Rab-GTPase-activating protein (GAP) with high homology to the insulin signalling protein AS160 (TBC1D4). The highest expression of TBC1D1 can be found in skeletal muscle, lower levels are also expressed in heart, pancreas and hypothalamus. In a positional cloning approach we previously identified a SJL mouse strain-specific loss-of-

function mutation in the *Tbc1d1*-gene that acts as an obesity suppressor. Our data indicated that mutation of *Tbc1d1* in mice was associated with adiposity due to elevated lipid use as well as decreased glucose uptake rates in skeletal muscle. In humans however, a rare *TBC1D1* variant (R125W) could be linked to an extreme form of familial obesity. The exact molecular mechanisms by which *TBC1D1* controls skeletal muscle metabolism and thereby influences whole body energy homeostasis are still unknown. In order to investigate the role of *TBC1D1* in energy homeostasis, we analyzed the impact of *TBC1D1* deletion in an established obese mouse model.

Materials and methods: The mutated *Tbc1d1*-allele from the lean SJL-strain was introgressed into an obese B6.V-Lep^{ob}/J background, a monogenic mouse model for obesity. Body weight and body composition (NMR) were analysed for 15 weeks. The respiratory quotient (RQ) and energy expenditure were measured by indirect calorimetry, food intake and voluntary physical activity (IRmot) was also determined. Carbohydrate- and fatty acid- metabolism were analyzed by measuring 2-desoxy-[1,2-³H]glucose uptake and [1-¹⁴C] palmitate oxidation in intact isolated skeletal muscle (EDL, Soleus).

Results: *TBC1D1*-deficient B6.SJL-Nob1.10-Lep^{ob}-mice had a significantly decreased body weight (49.5±0.6 vs. 45.7±0.8 g; *p*=0.00059) at week 15 which mainly resulted from reduced fat mass. Furthermore *TBC1D1*-deficiency led to a decreased RQ (dark phase: 1.022±0.009 vs. 0.994±0.011; *p*=0.065) which indicates a higher fat utilisation. These mice also displayed increased energy expenditure in the dark phase (2.63±0.03 vs. 2.79±0.03 kJ/g lean mass; *p*=0.0093). Isolated skeletal muscle of *TBC1D1*-deficient mice showed significantly reduced insulin-stimulated glucose uptake in glycolytic EDL muscle (4.63±0.40 vs. 3.26±0.19 nmol/mg/20 min; *p*=0.0019) while basal palmitate oxidation in oxidative soleus muscle was increased (2.09±0.16 vs. 3.11±0.31 pmol/mg/min; *p*=0.0093). There were no differences in food intake at 16 weeks of age (0.116±0.004 vs. 0.112±0.007 g/g body weight) and voluntary physical activity (132187±23875 vs. 158226±41128 beam breaks/24h) in *TBC1D1*-deficient mice compared to the controls.

Conclusion: Our data strongly indicate that *TBC1D1* influences whole body energy homeostasis by regulating the substrate flux of glucose and fatty acids in skeletal muscle. Since a role of *TBC1D1* in the neuronal control of food intake can be excluded, an increased fat oxidation in skeletal muscle is likely causal for the obesity-suppressive effect of *Tbc1d1* deletion. A detailed understanding of the function of *TBC1D1* can provide a new approach for a successful therapy of obesity.

Effects of frequent weight cycling on longevity in C57BL/6 and 129Sv mice

M. Kern¹, N. Klötting², J. Hebebrand³, M. Stumvoll¹, M. Blüher¹;

¹Department of Medicine, University of Leipzig, Germany, ²Integrated Research and Treatment Centre Adiposity Diseases, University of Leipzig,

³Department of Child and Adolescent Psychiatry and Psychotherapy, University of Duisburg-Essen, Germany.

Background and aims: The majority of obese patients cannot maintain hypo caloric diets over a longer period of time. As a consequence weight cycling is a frequent phenomenon in long term treatment of obesity. Long-term studies on weight cycling and intentional weight loss suggest that non-pharmacological and non-surgical treatment of obesity might entail elevated mortality rates. Therefore, we tested the hypothesis that weight cycling reduces life span in comparison to both permanent hyper caloric and normal nutrition in two different mouse strains.

Materials and methods: In female 129S6/SvEvTac (N=90) and C57BL/6NTac (N=90) the effects of a continuously caloric restriction, a life-long high fat diet (Sniff, E15772-34) and weight cycling, which was realized with a 4 week period change between both extremes of diet, on longevity have been determined. Body weight was recorded weekly. Intraperitoneal insulin tolerance (ITT) test was performed at the age of 24 and 51 weeks and the HbA1c was analyzed at the age of one year. Basal metabolic rate was measured with metabolic chambers (TSE, Bad Homburg, Germany).

Results: The average life expectancy for weight cycling animals (129S6/SvEvTac average age at death: 21.5±5 month and C57BL/6NTac 21.5±3.5 month) was comparable with the controls under chow diet (129S6/SvEvTac average age at death: 23.5±5 month and C57BL/6NTac 21.1±4 month). The permanent high caloric diet group had a 3.5 month shorter life span than the two other groups (129S6/SvEvTac average age at death: 20.5±5 month and C57BL/6NTac 17.1±4.8 month). 129S6/SvEvTac mice lived 1.5 months longer than C57BL/6NTac mice (*P*<0.0001). In addition, significant differences be-

tween the dietary regimens were found for measures of insulin sensitivity (ITT), glucose metabolism (HbA1c) and energy expenditure.

Conclusion: Frequent weight cycling significantly improved longevity compared to a lifelong high fat diet. There was no difference in the life span of mice undergoing weight cycling and permanent chow diet.

ASP-C5L2 pathway disruption influences the development of insulin resistance

A. Fiset¹, M. Munkonda, D. Gauvreau, S. Pagliarunga, K. Cianflone; Université Laval, Quebec, Canada.

Background and aims: Acylation Stimulating Protein (ASP) is an adipose tissue secreted hormone that derives from the immune system. ASP positively contributes to lipid and glucose uptake in adipocytes, increasing triglyceride storage. ASP acts through the C5L2 receptor, found in adipocytes and also in muscle, liver, brain and several immune cells. The ASP-C5L2 pathway is implicated in energy expenditure and has been linked with systemic inflammation. C5L2-deficient mice (C5L2KO) show an obesity-resistant phenotype, conferring a therapeutic potential to the disruption of the ASP-C5L2 pathway. However, previous studies suggest that ASP could also play a role in the development of insulin resistance. This study examines in details energetic metabolism and chronic inflammation alterations in C5L2KO mice with respect to insulin resistance progression.

Materials and methods: We used a diabetogenic regimen (high-fat/high-sucrose diet) for 12-week in C5L2KO and wild type (WT) mice. We performed glucose and insulin tolerance tests, injected radioactive tracers and assessed tissue and plasma metabolic, genetic and inflammatory parameters in all mice.

Results: Our work shows an exaggerated response with increased insulin resistance in C5L2KO mice compared to WT animals when fed a diabetogenic diet. Similar glucose clearance is achieved in C5L2KO mice only with vastly superior insulin levels (*p*<0.001) while a steady bolus of insulin failed to reduce blood glucose in C5L2KO mice as much as in WT mice (*p*<0.05). In addition, we demonstrated that C5L2KO mice show a significant shift in metabolic fuel usage in major organs related to energy expenditure and storage. Glucose uptake was reduced by more than 50% in adipose tissue and skeletal muscle while increased by 30% in liver (*p*<0.05 for all). We also show evidence of a chronic proinflammatory phenotype in C5L2KO mice, linked with a rise in circulating cytokines (such as IL6, IL10, KC and MIP-1), as well as increased macrophages infiltration and polarization in the adipose tissue.

Conclusion: Our study suggests that the ASP-C5L2 pathway may play an important role in the development of obesity co-morbidities such as type 2 diabetes through an energetic metabolism-immune system synergy.

A maternal high fat diet modulates energy intake in adult offspring in Gpr1/- mice

F. Keyhani Nejad^{1,2}, F. Isken^{1,2}, A.F.H. Pfeiffer^{1,2}, M. Kruse¹;

¹Dept. of Clinical Nutrition, German Institute of Human Nutrition, Nuthetal, ²Dept. of Endocrinology, Diabetes and Nutrition, Charité - University Medicine, Berlin, Germany.

Background and aims: Evidence from a variety of animal studies indicates that maternal high fat diet (HFD) consumption programs offspring for increased risk of adult obesity, hyperphagia and increased preference for fatty foods. Among potential mechanisms for perinatally applied HFD induced programming of obesity and hyperphagia are elevated inflammatory cytokines, since many neural systems that are critical in regulating energy balance are sensitive to circulating cytokine levels. There is also a line of evidence that inhibition of GIP signaling prevents the onset of HFD induced obesity. Little is known about the impact of consuming a HFD in adulthood in offspring that were exposed to a HFD during pregnancy and lactation (IU/L), which represents the western lifestyle more realistically than solely exposing mice to a HFD during IU/L. Up to now it is unclear if a HFD during IU/L can program alterations in adiposity or food intake in mice which lack GIP receptor signalling. We hypothesize that GIP receptor knock out (Gipr^{-/-}) mice are protected from dysregulated energy balance due to HFD applied during IU/L.

Materials and methods: Female GIP receptor heterozygous (Gipr^{+/-}) mice on a C57Bl/6J background had ad libitum access to either HFD (60% fat, HFD IU/L) or control diet (CD, 10% fat, CD IU/L) for 2 weeks prior to mating with Gipr^{+/-} male mice and during pregnancy and lactation. Male Gipr^{+/-} and wild type (WT) offspring were maintained on a normal rodent chow for 22 weeks. Then, mice were fed the same HFD used during the IU/L period for further 20 weeks. Body weight and food intake were determined weekly. At the end of the study, when mice were at the age of 45 weeks, expression of cytokines (MCP1, MIP1alpha) and adiponectin in epididymal adipose tissue were measured by quantitative RT-PCR. HPRT was used as a normalizing gene.

Results: No significant differences in body weight and food intake between WT and Gipr^{+/-} mice, which were exposed to either HFD IU/L or CD IU/L, were observed during the first 22 weeks on normal chow. Re-exposure to HFD in adulthood significantly increased body weight at the age of 45 weeks in WT on a CD IU/L compared to Gipr^{+/-} on a CD IU/L (50.61 ± 0.88 g vs. 43.98 ± 0.93 g, respectively, $p < 0.01$). Although cumulative energy intake (Kcal/BW) increased in WT on a HFD IU/L compared to WT on a CD IU/L, food consumption in Gipr^{+/-} on a HFD IU/L was significantly reduced compared to Gipr^{+/-} on a CD IU/L (39.76 ± 0.71 vs. 44.17 ± 1.04 kcal/BW, respectively, $p < 0.05$). The interaction of diet (IU) and genotype in food intake was significant ($p < 0.01$). The reduced adiposity in Gipr^{+/-} mice on CD and HFD IU/L compared WT mice on a CD IU/L was associated with a marked increase in adiponectin expression level and a significant reduction in a sub-class of inflammatory cytokines (MCP1, MIP1alpha) in epididymal adipose tissue.

Conclusion: The decreased food intake in Gipr^{+/-} on HFD IU/L mice is an unexpected and novel result. Reduced adiposity and inflammatory cytokine expression induced by inhibition of GIP signaling may play a role in producing long-term decrease in food intake even after re-exposure to HFD in adulthood.

Does rimonabant independently affect NEFA and glucose metabolism?

J.M. Triay¹, M. Mundi¹, S. Klein², F. Toledo³, S. Smith⁴, M.D. Jensen¹; ¹Endocrine Research Unit, Mayo Clinic, Rochester, ²Washington University of St Louis, St. Louis, ³University of Pittsburgh Medical Center, Pittsburgh, ⁴Translational Research Institute for Metabolism and Diabetes, Florida Hospital, Winter Park, USA.

Background and aims: Endocannabinoid receptor 1 blockade is proposed to improve metabolic complications of obesity via reduction of food intake (CNS mechanisms) and peripheral effects on adipose, liver and muscle. This sub-study of the Visceral fat reduction assessed by CT scan On Rimonabant (VICTORIA) trial directly compared a lifestyle weight loss program with rimonabant 20mg/day versus placebo on insulin regulation of non-esterified fatty acids (NEFA) and glucose metabolism in vivo.

Materials and methods: Sixty-seven volunteers age 35 to 70 with abdominal obesity and 2 other metabolic syndrome features (excluding diabetes) had measures of total body, visceral and fat free mass (FFM) (DXA; abdominal CT) and 2-step (0.25 and 1.0mU/kg/FFM/min) euglycemic hyperinsulinemic clamps at 0 and 12 months to measure: 1) insulin concentration to suppress plasma NEFA (palmitate) concentration 50% (IC50_{pal}); 2) insulin regulation of glucose disposal (slope of glucose disappearance rate vs. plasma insulin); 3) insulin concentration to inhibit hepatic glucose output 50% (IC50_{HGO}). Complete glucose data for 44 subjects (23 placebo) and NEFA data for 41 (21 placebo).

Results: Percent body fat in both groups fell from baseline (rimonabant 4.5% $p < 0.0001$, placebo 2.1% $p = 0.05$). There was a significant reduction in IC50_{pal} with rimonabant correlating with BMI change ($p = 0.005$, $r = 0.60$), however, this was not significantly different from placebo ($p = 0.5$) when controlling for greater BMI loss. Regulation of glucose disposal improved markedly in both groups ($p = 0.002$, $r = -0.29$) and correlated with visceral fat loss. Although the mean IC50_{HGO} did not change significantly from baseline in either group, intra-individual changes in IC50_{HGO} in the rimonabant group were correlated with changes in visceral fat ($p = 0.006$, $r = 0.42$).

Conclusion: In summary, rimonabant had no additive effect on insulin regulation of NEFA beyond that explained by fat loss alone; intra-individual changes in insulin regulation of hepatic glucose output were correlated with changes in visceral fat and insulin regulation of NEFA in the rimonabant group; insulin regulation of glucose disposal corresponded with visceral fat loss.

Serum nitrotyrosine in metabolically obese normal weight individuals

N. Kapoor, N. Deshpande, S. Aman, R. Kalpekar, K. Bhagwat, R. Parmaj; Belgaum Diabetes Centre, India.

Background and aims: An association between obesity, inflammation and endothelial dysfunction is known. Oxidative stress & nitrosative cell damage are said to mediate these effects. Free radicals such as superoxide lead to the generation of a potent oxidant called peroxynitrite. Nitrotyrosine (NT), measured in circulation, is a surrogate marker of this process. Normal weight obesity is defined as a high body fat percent (BFP) ($>20\%$ for men, $>30\%$ for women) with normal body weight (BMI <25 kg/m²). This group seems to have an equally high risk for metabolic diseases as that of a frankly obese group. We hypothesize that this group has increased oxidative stress which could be manifested as raised NT levels. In this study, we aim to compare serum NT levels in normal weight (NW), obese (O) & Normal weight Obese (NWO) individuals.

Materials and methods: 150 non diabetic, non hypertensive healthy adults (>18 years) were randomly selected & divided into 3 groups - NW, O, NWO. Anthropometry including body composition (Body mass index, Body Fat Percentage, Waist Circumference, Fat free mass, Waist Hip Ratio) was assessed using Bioelectric Impedance Analysis-Inbody230. The serum NT (ELISA - BIOXYTECH Enzyme Immunoassay for Nitrotyrosine) & high sensitivity C-reactive protein (HsCRP) were assessed.

Results:

OBESITY →	Normal weight n = 14	Normal weight Obese n = 28	Obese n = 34	Normal weight n = 8	Normal weight Obese n = 17	Obese n = 49
	Males			Females		
Sex						
Mean Age	43.1	48.8	47.1	47.4	47.2	46.9

MEAN BMI	19.05	25.2	27.5	20.2	22.3	28.7
MEAN BODY FAT PERCENTAGE	14.5	30.1	32.35	26.7	36.6	45.1
MEAN FAT FREE MASS	45.0	47.86	52.4	35.07	33.5	36.8
NITROTYROSINE ng/ml	1.15	1.8	1.18	0.315	6.95	4.94
HsCRPmg/dl	0.66	1.28	1.76	0.68	1.34	3.53

1. There is a significant difference in BFP among NWO & NO groups. This difference is seen in both males ($p < 0.0001$) & females ($p < 0.0001$).
2. NT levels are higher in NWO group as compared to NW group in both males & females.
3. NT levels were significantly higher in female NWO compared to male NWO group ($p = 0.005$).
4. The BFP is significantly higher in the female NWO group when compared to male NWO group ($p = 0.0002$).
5. HsCRP progressively increases across the 3 groups NW, NWO, & O.
6. NT levels in the NWO group were higher than those in O group.

Conclusion:

1. The significantly higher BFP in NWO groups justifies its classification. The NWO group has a higher risk of oxidative stress as measured by Nitrotyrosine than NW group. Hence NWO group is also a target for preventive strategies.
2. Females are more prone to oxidative stress than males probably because of their sedentary life style, higher visceral fat & poor exercise practices due to social circumstances in a developing country like India.
3. HsCRP, a marker of inflammation, progressively increases in NW, NWO & O groups. However NT level is maximum in the NWO group. Probably, the increased ratio of Fat Free mass Vs Fat mass in the obese Individuals makes these individuals comparatively less prone to oxidative stress when compared to NWO group that have high fat percentage & low skeletal muscle mass.

Metabolic consequences of obesity in a rural setting of BangladeshA. Akhter¹, M.S. Flora², K. Fatema³, L. Ali³;¹Department of Epidemiology, Bangladesh Institute of Health Sciences (BIHS), ²Department of Epidemiology, National Institute of Preventive and Social Medicine (NIPSOM), ³Department of Biochemistry and Cell Biology, Bangladesh Institute of Health Sciences (BIHS), Dhaka, Bangladesh.

Background and aims: The high prevalence of diabetes, hypertension and dyslipidemia are the manifestations of a pattern of metabolic disturbances related to obesity which has not received due attention in many developing countries. This study aims to describe the link of these manifestations to obesity in a rural Bangladeshi adult population, where conventionally obesity is thought to be a less important problem and so as to inform policy and lay the ground for surveillance interventions.

Materials and methods: This population based cross-sectional study was conducted through screening in camp settings in remote rural areas of Northern Bangladesh, which included a total of 836 participants (468 male and 368 female), aged at or above 30 years. Sociodemographic information was collected through semi-structured data collection form. Anthropometric (BMI and WHR) and clinical data were collected by standardized techniques. WHO guideline for Asian population were used to identify obesity with BMI 18.5–22.9 kg/m² as normal, 23.0–24.9 kg/m² overweight and above 25.0 kg/m² as obese. Central obesity was evaluated by WHR, with cut-off points taken at 0.8 for females and 0.9 for males. OGTT and lipid profile were also preformed. Glucose (fasting and 2 hr after glucose) was measured by glucose oxidase method, total cholesterol, triglyceride and HDL were analyzed by enzymatic-colorimetric method and LDL was estimated by Friedewald's formula. Logistic regression analysis was used with adjustment for potential confounders.

Results: The mean (\pm SD) age (years) of the participants was 46 (\pm 12), BMI (kg/m²) 22.1 (\pm 3.4) and WHR was 0.92 (\pm 0.06). As per criteria followed for Asian population about 38.5% (95% CI 35.2–41.8) of the participants had BMI in the overweight (18.4%) to obese (20.1%) range and 52.7% (95% CI 49.3–56.1) having high risk considering WHR. There was a significant female preponderance in both cases ($p < 0.04$ to 0.02) compared to males. Proportion of diabetes, prediabetes, hypertension and dyslipidemia among this population were 7.2% (95% CI 5.4–9.0), 6.5% (95% CI 4.8–8.2), 25.4% (95% CI 22.5–28.3) and 51.6% (95% CI 48.3–54.9), respectively. Influences of obesity were observed on glycemic status ($\chi^2 < 0.001$), hypertension ($\chi^2 = 0.024$) and dyslipidemia ($\chi^2 = 0.037$). After adjustment for socio-demographic variables, effect on lipid level disappeared. Diabetics (OR, 2.83 with 95% CI, 1.52–5.41) and hypertensives (OR, 1.96 with 95% CI, 1.17–4.63) were about 3 and 2 times, respectively, more likely to be obese in this population.

Conclusions: The data suggest that, an alarming proportion of adult Bangladeshi population have generalized as well as central obesity. Obesity is widely prevalent and may represent a silent epidemic even in this rural population. There is an urgent need for strategies and programs to prevent and control obesity, and thus reduce the metabolic burden in the rural population of Bangladesh.

Discriminant features of “metabolically healthy obese” and “metabolically obese normal weight” phenotypes in healthy postmenopausal womenM. Peppas¹, C. Koliaki¹, E. Boutati², E. Garoflos¹, A. Papaefstathiou¹, N. Katsilambros³, S.A. Raptis^{2,4}, G. Dimitriadis², D. Hadjidakis^{1,2};¹Endocrine Unit, Second Department of Internal Medicine-Propaedeutic, Research Institute and Diabetes Center, Attikon University Hospital,²Second Department of Internal Medicine-Propaedeutic, Research Institute and Diabetes Center, Attikon University Hospital, ³Evgenidion Hospital,⁴Hellenic National Diabetes Center for the Prevention, Research and Treatment of Diabetes Mellitus and its Complications (H.N.D.C.), Athens, Greece.

Background and aims: Although obesity is generally associated with increased cardiovascular risk, not all obese individuals exhibit cardiometabolic abnormalities and not all normal-weight subjects are protected against cardiometabolic disease. This allows classification into the following phenotypes: Metabolically Healthy (MHO) and Unhealthy (MUO) Obese, Metabolically Healthy (MHNW) and Obese (MONW) Normal Weight. Recent research has

focused on potential factors that could predict the above subtypes. Aim of the present study was to evaluate the specific patterns of body composition and fat distribution in all these phenotypes, and their association with blood pressure and indices of obesity, inflammation and insulin resistance, in healthy postmenopausal women.

Materials and methods: A cross-sectional study was performed in 150 postmenopausal women (age 54 ± 7 years, BMI 29.6 ± 5.8 Kg/m²). Based on a detailed 7-item cardiometabolic risk score, normal-weight women were subdivided into MONW ($n=38$) and MHNW ($n=22$), if they had ≥ 2 or 0–1 cardiometabolic abnormalities, respectively. Accordingly, obese women were classified into MHO ($n=22$) and MUO ($n=68$). Physical activity status, blood pressure and a full biochemical profile were evaluated, including high-sensitivity C-reactive protein (hs-CRP) measured by nephelometry. Body composition and fat distribution were evaluated by DXA (Hologic QDR Discovery).

Results: MONW women displayed significantly longer duration of menopause, higher waist circumference, blood pressure, fasting glucose, insulin, total and LDL cholesterol, hepatic aminotransferases, fibrinogen and hs-CRP levels, compared to MHNW ($p < 0.05$). Moreover, they exhibited higher height-adjusted lean body mass, and central adiposity indices, including trunk, abdominal and thoracic fat, as well as abdominal/gluteofemoral and trunk/legs fat ratio ($p < 0.05$). Similar but more pronounced differences were observed in the MUO, compared to MHO. Multivariate binary logistic regression analysis, revealed that duration of menopause ($p=0.05$), trunk/legs ($p=0.04$) and abdominal/gluteofemoral fat ratio ($p=0.005$) could classify correctly 78% of normal-weight and obese women into metabolically healthy and unhealthy phenotypes.

Conclusion: The “Metabolically obese phenotype” exists both in normal-weight and obese postmenopausal women and is associated with hypertension, insulin resistance, dyslipidaemia, inflammation and abnormal fat distribution. DXA-derived parameters, such as abdominal/gluteofemoral and trunk/legs fat ratio, can identify abnormal phenotypes and may serve as predictors of cardiometabolic risk in postmenopausal women.

667

Effect of abdominal weight gain and weight loss on insulin sensitivity and insulin secretion in adults who maintain normal glucose regulation during a 5-year periodK. Færch¹, D. Vistisen¹, T. Jørgensen², D.R. Witte¹;¹Steno Diabetes Center, Gentofte, Denmark, ²Research Centre for Prevention and Health, Glostrup, Denmark.

Background and aims: To improve prevention of type 2 diabetes it is important to understand how glucose homeostasis is regulated in healthy individuals. We studied how insulin sensitivity as well as absolute and relative insulin secretion changed in response to abdominal weight gain and abdominal weight loss in individuals maintaining normal glucose regulation during a 5-year period.

Materials and methods: From the population-based, non-pharmacological intervention study Inter99 we included 2,514 participants with HbA_{1c} $< 6.0\%$ both at baseline and after 5 years. All were classified as having either increased or decreased their waist circumference (WC) during the 5-year period. Participants who increased ($n=1,820$) and decreased ($n=694$) their WC were further divided into tertiles, resulting in 6 different groups (small, medium and large WC increase, and small medium and large WC decrease). From OGTTs performed at baseline and after 5 years we estimated insulin sensitivity, absolute early insulin secretion as well as relative beta cell function (i.e. the disposition index).

Results: Estimates of insulin sensitivity and insulin secretion were standardized before analysis. Differences between groups of WC change were tested in linear regression models adjusted for age, sex, intervention group, 5-year change in HbA_{1c}, baseline WC, and baseline variables of insulin sensitivity, absolute or relative insulin secretion where relevant. Changes in WC were associated with changes in insulin sensitivity in a dose-dependent manner (P for trend < 0.001 ; Figure 1). The pattern of absolute insulin secretion was somewhat different (P for trend = 0.127). The increase in absolute insulin secretion was highest in participants with the largest increase in WC ($P < 0.001$), whereas the change in absolute insulin secretion did not differ between the groups with small, medium and large abdominal weight loss ($P \geq 0.279$). The change in disposition index did not differ between the three groups who gained abdominal weight ($P \geq 0.487$), but the disposition index improved more in participants with a large abdominal weight loss compared to participants with a small abdominal weight loss ($P=0.012$).

Conclusion: The changes in insulin sensitivity and insulin secretion in response to abdominal weight gain and abdominal weight loss are not similar. Therefore, it cannot be assumed that the adverse effects observed after abdominal weight gain are restored in response to abdominal weight loss.

Figure 1: Unadjusted differences (SD) in absolute early insulin secretion, insulin sensitivity and disposition index in persons with small, medium and large waist increase (upper panel) and persons with small, medium and large waist decrease (lower panel).

The association between body fat and circulating complement C3 is largely explained by low-grade inflammation and insulin resistance: the CODAM study

N. Wlazlo^{1,2}, M.M.J. van Greevenbroek², I. Ferreira^{2,3}, C.J.H. van der Kallen², C.G. Schalkwijk², B. Bravenboer¹, C.D.A. Stehouwer²

¹Department of Internal Medicine, Catharina Hospital Eindhoven,

²Department of Internal Medicine / Laboratory for Metabolism and Vascular Medicine, Maastricht University Medical Centre, ³Department of Clinical Epidemiology and Medical Technology Assessment, Maastricht University Medical Centre, Netherlands.

Background and aims: Serum complement factor 3 (C3) has been linked to type 2 diabetes mellitus and cardiovascular diseases. C3 levels are closely related to body fat, but the underlying mechanisms explaining this association are still unknown. The present, cross-sectional study investigated the role of low-grade inflammation and insulin resistance in adiposity-related increases in C3, since both are known correlates of adiposity and C3.

Materials and methods: Adiposity measures (including waist circumference (WC), body mass index (BMI), sagittal diameter and several skinfolds), serum C3, HOMA2-IR and markers of inflammation (hs-CRP, IL-6, SAA, haptoglobin, ceruloplasmin, sICAM-1) were determined in 534 individuals (62% men, age 59±6.9 yrs) from the CODAM study. Markers of inflammation were standardized and compiled into an average inflammation score. Associations between adiposity measures and C3 were analysed with linear regression models, and multiple mediation analyses were performed to ascertain the extent to which any such associations were explained by inflammation and/or HOMA2-IR.

Results: Adiposity measurements were significantly associated with C3 levels, with the strongest (adjusted) associations found for WC ($\beta=0.385$; 95%CI 0.305-0.466) and sagittal diameter ($\beta=0.413$; 95%CI 0.335-0.491). Further adjustment for inflammation and HOMA2-IR attenuated these associations to $\beta=0.119$ (95%CI 0.034-0.204) and $\beta=0.167$ (95%CI 0.086-0.248) respectively. Multiple mediation analyses showed that inflammation [$\beta=0.091$ (95%CI 0.060-0.127)] and HOMA2-IR [$\beta=0.176$ (95%CI 0.126-0.229)] each explained, independently of one another, a significant portion of the association between WC and C3 (24% and 46%, respectively). Similar mediation by inflammation (19-28%) and HOMA2-IR (36-55%) was found for other adiposity measures (Fig. 1).

Conclusion: Systemic low-grade inflammation and insulin resistance seem to represent two independent pathways by which body fat leads to elevated C3 levels.

Figure 1: Associations between adiposity measures and serum C3, ordered from strongest to weakest; portions of the overall associations independently explained by low-grade inflammation are given in grey (19-28%) and by HOMA2-IR are given in black (36-55%). Portions that remained unexplained are given in white.

Insulin sensitivity, beta cell function and subclinical inflammation in the baboon, a non human primate model of insulin resistance, obesity and type 2 diabetes

F. Folli¹, F. Casiraghi¹, A.M. Davalli^{1,2}, S. Kamath¹, A. Ricotti^{1,3}, Z. Chang¹, A. Gastaldelli^{1,3}, G.A. Abrahamian⁴, G.A. Halff⁴, R.A. DeFronzo¹, A.O. Chavez¹

¹Medicine/Diabetes, UTHSCSA, San Antonio, USA, ²Medicine, HS Raffaele, Milan, Italy, ³Institute of Clinical Physiology, CNR, Pisa, Italy, ⁴Transplant Center, UTHSCSA, San Antonio, USA.

Background and aims: Insulin resistance and beta cell dysfunction are hallmarks of type 2 diabetes mellitus (T2DM) in humans. They are early findings of impaired glucose homeostasis in obesity. Previously we have characterized the metabolic and insulin signaling defects in target tissues in nondiabetic baboons. Obesity and insulin resistance occur naturally in baboons and may be associated to low grade systemic inflammation. Here we sought to assess beta cell function and insulin sensitivity in baboons, and the relationship between circulating cytokines with glucose levels and anthropometric measures of adiposity.

Materials and methods: We studied 46 nondiabetic baboons in basal conditions, in which we measured anthropometric measures of adiposity such as waist circumference, BMI and percent body fat (%BF) by DXA, and performed a two step hyperglycemic clamp with arginine stimulus to assess both beta cell function and insulin sensitivity. Partial correlations were performed between insulin sensitivity (M/I), acute insulin response (AIR_{0-12}), second phase insulin (AUC_{12-180}) secretion and arginine potentiated insulin secretion ($AUC_{Arg_{180-210}}$), in addition to body composition. On a separate cohort of animals (n=80) ranging the whole span of adiposity representative of animals living in wild conditions, we measured circulating sTNF-R1 and sIL6-R levels in order to correlate them with glucose metabolism and adiposity.

Results: Waist circumference was strongly correlated with total percent body fat ($r^2=0.72$ $p<0.0001$) and trunk fat ($r^2=0.41$, $p<0.01$) in our study population. Waist circumference, BMI, and total body weight showed a markedly gender dimorphism although the strong relationship with percent body fat was maintained in both males and females. During the hyperglycemic clamp, M/I was negatively correlated with total insulin secretion ($r^2=0.70$, $p<$), AIR_{0-12} ($r^2=0.12$, $p=$), 2nd phase ISEC₀₋₁₈₀ and ISEC_{ARG} (both $r^2=0.66$, $p<0.0001$) during each stage of the clamp and with the ratio between insulin and glucagon secretion ($r^2=0.30$, $p<0.0001$). M/I did not correlate with glucagon secretion in the clamp. Finally, sTNF-R1 correlated with fasting plasma glucose ($r^2=0.19$, $p<0.0001$). Weight showed a correlation with sIL6-R ($r^2=0.09$, $p<0.004$), sTNF-R1 levels correlated with sIL6-R ($r^2=0.10$, $p=0.003$).

Conclusion: Insulin secretion during the hyperglycemic clamp correlated inversely with insulin sensitivity in baboons in the nondiabetic range. Also, progressive increase in fasting plasma glucose in the nondiabetic range was directly correlated to an increase in circulating markers of subclinical inflam-

mation known to be strongly correlated with insulin resistance in humans by dysregulation of the TIMP-3/TACE dyad, with increased production of TNF- α and IL6. These results further establish the use of baboons as a valuable non human primate model for the study of complex metabolic diseases such as obesity, insulin resistance and T2DM.

Lower weight gain and better outcomes in patients with type 2 diabetes starting insulin treatment when baseline HbA_{1c} <8.0%

J. Leahy¹, A. Vlainic², M. Rimler³;

¹University of Vermont College of Medicine, Burlington, USA, ²sanofi-aventis US, Bridgewater, ³Medpace, Cincinnati, USA.

Background and aims: Weight gain is a commonly perceived effect of using insulin in type 2 diabetes (T2D).

Materials and methods: We examined weight gain in the context of treatment efficacy and safety using pooled data from 9 randomized, controlled, clinical studies of adult patients with T2D. In each study, insulin glargine was tested against a comparator (63% other insulins, 32% OADs, 6% dietary) over 24 weeks. Weight gain was assessed by treatment, demographics, age, and baseline A1C and FPG. The analysis included 2900 patients (Glargine: n=1449; Comparator: n=1451).

Results: Patients were 56% male, 84% white, mean (SD) age 57 (9.8) years, and T2D duration 8.6 (6.1) years. Mean weight gain was similar for Glargine-treated patients vs Comparator (2.2 kg vs 2.1 kg). However weight gain was lowest in patients with baseline A1C <8%, rising with higher A1C. Results were similar for baseline FPG. Also patients ≥ 65 years gained less weight during treatment than younger patients and weight gain was significantly lower as a patient's age increased. More patients achieved A1C $\leq 7\%$ with Glargine (58.3%) vs Comparator (52.7%) (OR=1.27, $P=0.0015$). Trend analysis showed older vs younger patients treated with Glargine were more likely to achieve A1C $\leq 7\%$ ($P=0.0055$); there was no such trend for Comparator. Glucose confirmed (<50 mg/dL) hypoglycemia occurred less often with Glargine treatment than Comparator, 1.5 vs 2.6 events/pt-yr, $P<0.0001$, with the lowest estimate among Glargine patients ≥ 65 years.

Conclusion: Weight gain with Glargine therapy is similar to that for Comparator, but varies with patients' demographics. Starting patients when A1C <8% leads to better efficacy, comparable safety, and minimizes weight gain. Also patients ≥ 65 years show the lowest weight gain and highest odds of achieving A1C $\leq 7\%$ with least hypoglycemia.

Fat distribution, HbA_{1c} and hypoglycaemia in overweight and obese patients with type 2 diabetes: a comparison of NPH and insulin detemir from a pilot randomised clinical trial

F.J. Tinahones¹, R. Gómez-Huelgas², J. García-Alegría³, M. Tapia-Guerrero⁴, F. Martos-Perez⁵;

¹Hospital Virgen de la Victoria, Malaga, ²Internal Medicine Department, Hospital Carlos Hayer, Malaga, ³Hospital Costa del Sol, Marbella, ⁴Hospital Carlos Haya, Malaga, ⁵Hospital De Alta Resolución, Benalmádena, Spain.

Background and aims: Weight gain and hypoglycaemia remain significant barriers to insulin intensification in type 2 diabetes (T2D), and the former may be of particular concern to patients who are overweight. Insulin detemir (IDet) has been shown to incur less weight gain than other basal insulins, which may facilitate greater patient acceptance of insulin.

Materials and methods: This was a 26-week, open-label, randomised trial designed to compare the effects of IDet and NPH insulin on weight parameters in overweight or obese patients with T2D. The primary endpoint was change in trunk fat mass, measured by double energy X-ray absorptiometry (DEXA). Secondary endpoints included weight change (kg), waist circumference, BMI, HbA_{1c} (%) and hypoglycaemia. Both basal insulins were administered once daily, with insulin aspart given at main meals. Patients taking OADs with the exception of metformin were excluded.

Results: Demographic characteristics were similar at baseline for IDet (n=24, mean age 60.6 years, 54.2% male, mean HbA_{1c} 8.3 %, mean BMI 32.2 kg/m², mean waist circumference 107.7 cm) and NPH insulin (n=35, mean age 63.7 years, 45.7% male, mean HbA_{1c} 8.3 %, mean BMI 34.0 kg/m², mean waist circumference 110.0 cm). Overall, changes in trunk fat mass, whole-body fat mass and weight were similar between the two groups, as was dose and glycaemic control, with a favourable trend towards IDet. IDet incurred a statistically significant lower risk of hypoglycaemia (see table). Differences were also noted for change in waist circumference at week 8 (-1.05 cm [5.21 SD, IDet group] vs. 1.34 cm [3.67 SD, NPH insulin group], $p=0.0173$) and week 12 (-0.9 cm [4.90 SD, IDet group] vs. 1.04 cm [3.47 SD, NPH insulin group], $p=0.045$), but these were not maintained at study end.

Conclusion: In summary, compared with NPH insulin treatment, IDet seems to result in a small reduction in waist circumference, a similar reduction in HbA_{1c} and significantly fewer episodes of hypoglycaemia.

Change from baseline at 26 weeks

	IDet (n=24)	NPH insulin (n=35)
Trunk fat mass (% change)	-0.38% (10.97)	-0.06% (12.57)
Whole-body fat mass (% change)	2.59% (12.39)	2.59% (12.39)
Weight change (kg)	0.89 kg (4.30)	1.90 kg (2.79)
HbA _{1c} reduction (%)	-0.79% (1.06)	-0.73% (1.16)
Number of hypoglycaemia events	6.42 (9.45)*	15.31 (20.90)
Daily basal insulin dose (U/kg)	0.41 (0.14)	0.47 (0.17)

Insulin upregulates natriuretic peptide clearance receptor expression in the subcutaneous fat depot in obese subjects: a missing link between CVD risk and obesity?

N.N. Rudovich¹, O. Pivovarova¹, Ö. Gögebakan¹, N. Klötting², M. Blüher³, A.F.H. Pfeiffer¹;

¹Clinical Nutrition, DIFE Potsdam-Rehbrücke, Nuthetal, ²Division of Nephrology Research Laboratory, University Hospital Leipzig,

³Endocrinology and Nephrology Clinic, Universität Leipzig, Germany.

Background and aims: Natriuretic peptides (NP) have multiple metabolic properties and NP concentrations have been shown to be down regulated in patients with central obesity. NP act via binding on three natriuretic peptide receptors (NPRs). Increased expression of natriuretic peptide clearance receptor (NPRC) in subcutaneous adipose tissue was observed in central obesity. We therefore tested hypothesis that insulin may regulate NPR expression in the fat tissue.

Materials and methods: NPR (A-C) mRNA expression was measured in paired samples of visceral (VAT) and subcutaneous adipose tissue (SAT) from 157 subjects with (n=72) or without (n=85) type 2 diabetes. The effect of insulin on NPR genes expression in SAT was studied in euglycemic-hyperinsulinemic and hyperglycemic-hyperinsulinemic clamp experiments in obese male subjects (n=14). Additionally, the effect of insulin and glucose on NPR expression in culture of primary human monocytes and macrophages was tested.

Results: NPRA and NPROC gene expression were higher in VAT compared with SAT ($p<0.01$), but only NPROC gene expression strongly correlated with fasting insulin levels ($r=0.65$, $p=0.04 \times 10^{-3}$ and $r=0.54$, $p=0.002$, for VAT and SAT respectively). NPROC gene expression was up-regulated in both euglycemic- and hyperglycemic-hyperinsulinemic clamps ($p=0.038$ and $p=0.048$, respectively). NPROC expression was increased in simultaneous insulin and glucose treatment in monocytes (70.2%, $p=0.01$), but not in mature macrophages.

Conclusion: Insulin increases expression of NPROC in SAT independently of glucose concentration. Thus insulin might suppress levels of circulating NP via upregulation of NPROC expression in obesity. Our observations provide a novel link between hyperinsulinemia, cardiovascular disease risk and the metabolic syndrome.

PS 048 Consequences of high fat diet

673

Influence of the high-fat diet on the circadian clock in human peripheral mononuclear blood cells

O. Pivovaro^{1,2}, S. Möckel¹, A. Busjahn³, A.F.H. Pfeiffer^{1,2};

¹Department of Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, ²Dept. of Endocrinology, Diabetes and Nutrition, Charité University Medicine, Campus Benjamin Franklin, Berlin, ³HealthTwist GmbH, Berlin, Germany.

Background and aims: The circadian clock coordinates various behavioral and physiological processes including feeding behavior and energy metabolism. In turn, metabolic processes feed back onto the circadian clock as shown in recent studies of obesity and type 2 diabetes. Moreover, animal studies demonstrated alterations of behavioral and molecular circadian rhythms induced by the high-fat diet. However, there is little to no information about the effect of nutritional components on circadian mechanisms in humans. To address this, we investigated the influence of a high-fat isocaloric diet on daily expression profiles of clock genes in human peripheral mononuclear blood cells (PBMC) and purified monocytes.

Materials and methods: The expression of 10 clock genes was determined by real-time PCR in twelve nonobese healthy individuals in terms of NUGAT (Nutrigenomics Analysis in Twins) study. Gene expression was measured in three time points (at 8:30, 11:45 and 16:00) during three investigation days. The blood sampling was carried out before the beginning of the high-fat isocaloric diet (45 % kcal from fat) and after one and six weeks of intervention.

Results: We firstly demonstrated that Per1, Per2, Per3, Bmal1, Rev-erba, Dbp and Tef are rhythmically expressed in human monocytes. The clock genes Clock, Cry1 and Cry 2 displayed no significant circadian rhythmic. In PBMC, similar temporal expression profiles were detected. In response to high-fat diet, in monocytes, the morning expression and amplitude of the Period genes Per1, Per2 and Per3 increased after one and/or six weeks of intervention and correlation analysis reveals stronger relationship between clock genes after six weeks of diet. In contrast, in PBMC fraction, we found no significant changes of clock gene expression and modest decrease of synchronisation of the clock gene mechanism after six weeks of diet intervention.

Conclusion: High-fat diet induces alterations of clock gene expression in human monocytes which are undetectable in heterogenic PBMC population. Therefore, the investigation of the purified monocytes as metabolic important immune cell fraction is of interest in human studies. Our results suggest that the consumption of a high-fat isocaloric diet can influence the circadian mechanism in human already after the short time intervention and emphasize the role of nutrition-clock interaction in the regulation of human metabolism.

Chemerin and chemokine-like receptor 1 in mice with high fat diet induced obesity

C. Ress, T. Sonnweber, M. Nairz, I. Theurl, C.F. Ebenbichler, G. Weiss, S. Kaser;

Department of Medicine 1, Medical University Innsbruck, Austria.

Background and aims: Chemerin is a recently discovered protein predominantly produced in the liver and adipose tissue. It has been shown to influence adipocyte differentiation and mediate chemotaxis as well as activation of dendritic cells and macrophages. These functions are partially mediated via chemokine-like receptor 1 (CMKLR1). Several studies suggested negative associations between chemerin and glucose tolerance. In humans, circulating chemerin levels decrease with significant weight loss after bariatric surgery, suggesting that chemerin might contribute to the negative relationship between obesity and insulin sensitivity.

Materials and methods: In this study we set out to investigate the influence of dietary fat content on circulating chemerin levels and the tissue specific expression patterns of chemerin and CMKLR1 in an animal model of diet-induced obesity. Ten male C57Bl/6 mice were fed either standard diet (fat content 12% kcal) or high fat diet (fat content 60% kcal) for 10 weeks. Circulating chemerin levels were determined by using a commercially available

ELISA. Chemerin as well as CMKLR1 mRNA expression levels in visceral, subcutaneous adipose tissue and liver tissues were quantified by fluorescence based real-time PCR.

Results: As expected body weight was significantly higher in mice fed a high fat diet than in standard diet fed mice (47.3 ± 4.1 g vs. 38.9 ± 1.7 g; $p < 0.01$). Circulating chemerin levels were significantly increased in high fat diet fed mice when compared to standard diet fed mice (109.4 ± 14.1 ng/ml vs. 88.1 ± 10.9 ng/ml; $p = 0.03$). CMKLR1/GAPDH cDNA ratios of visceral and subcutaneous adipose tissue and the liver were unaffected by dietary fat content. Chemerin/GAPDH cDNA ratios in both subcutaneous and visceral adipose tissue were also similar in high fat and standard diet fed mice. Hepatic Chemerin expression tended to be higher in high fat diet fed mice without reaching statistical significance.

Conclusion: In conclusion, circulating chemerin levels are significantly increased in diet-induced obese mice. Elevated circulating Chemerin might not result from increased chemerin expression levels in adipose tissue or the liver but by enlarged mass of adipose tissue in obesity. Our data suggest that chemerin might be another component linking high fat diet and insulin resistance.

Selective breeding of mice which are prone and resistant to high fat diet-induced obesity and hyperglycaemia

Y. Sato, M. Nagao, A. Asai, Y. Nakajima, M. Takaya, S. Takemitsu, M. Sudo, T. Harada, K. Tanimura, F. Okajima, H. Sugihara, S. Oikawa;
Division of Endocrinology and Metabolism, Department of Medicine, Nippon Medical School, Tokyo, Japan.

Background and aims: To elucidate key factors for regulating susceptibility to high fat diet (HFD), we have conducted a selective breeding to establish two strains of mice which exhibit hyperglycemia with obesity and normoglycemia without obesity after 5-week HFD feeding; designated Selectively bred Obese and Diabetes Prone (SOD-P) and Resistant (SOD-R) mice, respectively. We previously demonstrated that SOD-P mice showed significantly higher blood glucose level and gained more body weight through the HFD feeding period compared with SOD-R mice.

Materials and methods: Each strain of mice fed a HFD (30% kcal fat) for 5 weeks (from 5 to 10 weeks of age), and oral glucose tolerance test (OGTT; 2g/kg body weight) was performed after HFD feeding. The mice, which exhibited higher and lower 2-h post-OGTT blood glucose concentration, were respectively selected for SOD-P and SOD-R, and have been bred over the 14th generations so far. To evaluate the characteristics of these selectively bred mice, OGTT and insulin tolerance test (ITT; 1U/kg body weight, i.p.) was performed before and after HFD exposure (at 5 and 10 weeks of age, respectively). Glucose stimulated insulin secretion (GSIS) from pancreatic islets was assessed by batch incubation of isolated islets.

Results: At 5 weeks of age, i.e., even before exposure to HFD, male SOD-P mice gained more body weight (19.9 ± 0.4 g in SOD-P, 18.7 ± 0.4 g in SOD-R; $P = 0.048$) and exhibited modestly higher blood glucose concentrations in OGTT ($P = 0.009$, AUC_{120min}), but similar glucose-stimulated plasma insulin response compared with SOD-R mice. In addition, SOD-P mice showed reduced insulin sensitivity in ITT. After HFD feeding (at 10 weeks of age), body weight of SOD-P and SOD-R was significantly different (32.0 ± 1.3 g and 25.5 ± 1.3 g, respectively; $P = 0.003$), and SOD-P mice showed higher blood glucose response in OGTT ($P = 0.008$, AUC_{120min}) and lower insulin sensitivity in ITT compared with SOD-R mice. There was no difference in plasma insulin response in OGTT. These results indicate that heritable glucose metabolism impairment and obesity in SOD-P mice become more evident by exposure to HFD. At 5 weeks of age, although apparent islet size was not different, GSIS from male SOD-P islets was impaired under high glucose (16.7 mmol/l) condition compared with SOD-R islets.

Conclusion: The present results indicate that HFD-induced weight gain and impaired glucose metabolism as heritable phenotypes were accelerated through the selective breeding study. The difference in susceptibility to HFD would enable us to establish these two strains of mice, SOD-P and SOD-R. The obese and diabetes prone SOD-P mice showed whole body insulin resistance and impaired GSIS in pancreatic islets even before HFD feeding. These factors may be crucial for determining the susceptibility to HFD-induced obesity and diabetes.

The effects of high-fat diet on intestinal and pancreatic functions with emphasis on perfusion and glucose uptake; validation of the [18 F]FDG radionuclide using simultaneous PET and CT imaging modalities

H. Honka¹, J.C. Hannukainen², M. Tarkia², A. Karmi¹, J. Mäkinen¹, V. Oikonen², A. Saraste², M. Teräs², J. Knuuti², V. Fagerholm², K. Mikkola¹, R. Kivelä³, P. Nuutila²;
¹University of Turku, ²Turku PET Centre, ³University of Helsinki, Turku, Finland.

Background and aims: Today intestine is regarded as highly active metabolic and endocrine organ. Changes in the secreted enteroendocrine hormone profile are crucial in the pathogenesis of the type 2 diabetes mellitus (T2DM). However, there is no consensus about the changes that precede the altered hormonal secretion; both circulatory dysfunction and altered nutrient uptake of the mucosal cells have been suggested. Our aim was to validate the use of positron emission tomography (PET) on the intestine and pancreas in a pig model and to compare the extents of perfusion (with radiowater, [15 O]H₂O) and glucose uptake (with fluorine-18 labeled glucose analogue [18 F]FDG) between diabetic and healthy swines.

Materials and methods: Twelve age-matched swines were randomized into two groups. Intervention group (n=6) were administrated with streptozotocin + high-fat diet in order to achieve obese and diabetic state. Simultaneous PET/CT was used in perfusion and glucose uptake scans. Multiple arterial plasma samples were collected to obtain plasma radioactivity measurements and metabolic parameters. Tissue samples from three parts of intestine (duodenum, ileum, colon) and pancreas (caput, corpus, cauda) were obtained. Autoradiography, histologic and immunohistochemical sections were prepared and tissue radioactivity was measured. Gjedde-Patlak plot was used to obtain PET derived Ki values.

Results: By the time of writing, most of the swines have been imaged and data obtained although no data-analyses have been executed. However, the following statements can already be made: 1) Autoradiography show that most of the glucose analogue accumulates in the mucosal layer of the intestine. This comprises the most metabolically active part of the intestinal wall. 2) Preliminary data indicate that both the pancreatic and even more intestinal perfusion is decreased in obese diabetic swines (73.5 vs. 54.2 ml/(100g min) for pancreas; 50.3 vs. 37.4 ml/(100g min) for duodenum; 56.1 vs. 35.4 (ml/100g min) for ileum; 21.7 vs. 15.4 (ml/100g min) for colon). In the case of intestine, this can be due to the endothelial dysfunction of the mucosal vessels induced by intervention (high-fat diet) or changes in secreted enteroendocrine profile via dorsal motor nucleus of the vagus (DMV) and splanchnic NANC (non-adrenergic, non-cholinergic) neurons. Histologic sections stained with Movat's pentachrome and glucose and fatty acid transporters enlighten these hypotheses. At this early stage it is not definite to say whether correction coefficient or function is needed between ex vivo and PET derived Ki values.

Conclusion: Our preliminary data show that both intestinal and pancreatic perfusion is decreased in obese diabetic subjects. Moreover, PET can indeed be used for the studies regarding intestine and pancreas. Further studies regarding the specific actions of enteroendocrine hormones on perfusion are needed. With fluorine-18 labeled radionuclide (including glucose and free fatty acid analogues) studies with PET being validated on the intestine and pancreas, a whole new highway for noninvasive metabolic studies will be opened.

N-3 fatty acids augment beneficial effects of calorie restriction in mice fed a high-fat diet: role of lipid mediators

P. Zouhar¹, P. Flachs¹, R. Rühl², M. Hensler¹, P. Janovska¹, Z. Macek Jilkova¹, E. Papp², O. Kuda¹, V. Kus¹, M. Rossmeisl¹, J. Kopecky¹;

¹Department of Adipose Tissue Biology, Institute of Physiology Academy of Sciences of the Czech Republic v.v.i., Prague, Czech Republic, ²Department of Biochemistry and Molecular Biology, Laboratory of Nutritional Bioactivation and Bioanalysis, University of Debrecen, Hungary.

Background and aims: Calorie restriction (CR) is an essential component in the treatment of obesity and associated diseases. n-3 long-chain polyunsaturated fatty acids (n-3 LC-PUFA) act as natural hypolipidemics, reduce risk of cardiovascular disease and could prevent development of obesity and insulin resistance. We aimed to characterize the efficacy and underlying mechanisms

of the combination treatment with n-3 LC-PUFA and mild CR in the prevention of obesity and associated disorders in mice.

Materials and methods: Male C57BL/6J mice were habituated to a corn oil-based high-fat diet (cHF) for 2 weeks and then randomly assigned to various dietary treatments for 5 weeks or 15 weeks: (i) cHF, ad libitum; (ii) cHF+F, cHF diet with n-3 LC-PUFA concentrate (EPAX 1050 TG) replacing 15% of dietary lipids, ad libitum; (iii) cHF+CR, cHF diet reduced by 10% as compared with the ad libitum cHF-fed mice; and (iv) cHF+F+CR.

Results: Compared with the cHF diet, the combination treatment (cHF+F+CR) most efficiently reduced body weight gain and the weight of both abdominal and subcutaneous white adipose tissue (WAT) depots, while it also improved insulin sensitivity (HOMA index) and glucose tolerance (OGTT). Ectopic lipid accumulation in the liver and skeletal muscle was also markedly decreased by the combination treatment. Moreover, the infiltration of WAT by macrophages, indicating a chronic low-grade inflammation of the tissue, was prevented by the cHF+F+CR treatment. Specifically in abdominal WAT, the conversion of PUFA to anti-inflammatory lipid mediators was additively induced by CR and n-3 LC-PUFA. For instance, the levels of 15-deoxy- $\Delta^{12,15}$ -prostaglandin J2 and neuroprotectin D1 were increased 6.6-fold and 35-fold, respectively, by the cHF+F+CR treatment as compared with the cHF mice. Furthermore, gene expression analysis revealed synergistic activation of PPAR α /PGC-1 α signalling pathways by the cHF+F+CR treatment in abdominal WAT, but not in the liver, muscle or brown fat. The above effects of the combination treatment correlated with the rate of palmitate oxidation and mitochondrial respiratory capacity in WAT. Thus, the maximal rate of palmitate oxidation measured in epididymal WAT *ex vivo* was 2-fold higher in the cHF+F+CR mice as compared with the cHF mice (60.01 ± 8.04 vs. 24.73 ± 5.67 pmol O $_2$ /s/mg DNA; $p = 0.012$), when measured in the presence of FCCP, an uncoupler of oxidative phosphorylation.

Conclusion: We show that n-3 LC-PUFA augment the anti-inflammatory and metabolic effects of CR through the induction of mitochondrial biogenesis and fatty acid oxidation in WAT, while inducing tissue-specific changes in the production of anti-inflammatory lipid mediators. Thus, this study reveals a new mechanism of anti-inflammatory and metabolic effects of n-3 LC-PUFA through the WAT-specific induction of anti-inflammatory lipid mediators including 15-deoxy- $\Delta^{12,15}$ -prostaglandin J2.

Bile acid mediated resistance to high-fat diet induced obesity is not mediated through bile acid (TGR5) receptor

M.D. Michael, T. Coskun, T.E. Fitch, D.A. Briere, C.C. Cheng, C. Suen; Endocrine, Eli Lilly and Company, Indianapolis, USA.

Background and aims: TGR5 has identified as a receptor activated by bile acids and activation of TGR5 receptor stimulates GLP1 and PYY secretion from enteroendocrine cells. Further, chronic exposure to high levels of bile acid leads to weight loss, and this has been suggested to be caused by TGR5 mediated increase of energy expenditure. In this study, we aimed to understand whether bile acid-induced weight loss is due to activation of TGR5 receptor.

Materials and methods: Lean or diet-induced obese C57/BL6 mice were fed by high fat diet alone or high fat diet containing 0.5% cholic acid for the duration of 12 weeks to assess bile acid induced prevention of weight gain or weight loss, respectively. Body weight and food intake were monitored every three days and body composition was measured every two weeks by quantitative nuclear magnetic resonance. Another group of wild-type and TGR5 null mice were also fed by bile acid diet.

Results: Cholic acid significantly prevented weight gain in lean mice throughout the study without affecting food intake. In diet-induced obese mice, cholic acid treatment significantly reduced weight loss (-10%) for up to 6 weeks. However, cholic acid also prevented high fat diet induced weight gain in TGR5 null mice.

Conclusion: These results suggest that the TGR5 receptor is of no importance in mediating bile acid induced resistance to high-fat diets.

The role of adipose tissue in insulin-sensitising and blood pressure lowering effects of ACE-inhibitors: studies on mice with diet-induced obesity and fatless mice

P. Kavalkova¹, J. Kunes², J. Zicha², M. Haluzik³, D. Haluzikova^{4,5}, Z. Lacinova⁴, M. Haluzik⁴;

¹3 Department of Medicine, Faculty of Medicine, ²Institute of Physiology, Academy of Sciences of CR, ³Department of Chemistry, University of Ostrava, ⁴3 Department of Medicine, Faculty of Medicine, ⁵Department of Sports Medicine, Faculty of Medicine, Prague, Czech Republic.

Background and aims: Inhibitors of angiotensin-converting enzyme (ACE) not only decrease blood pressure but also improve insulin sensitivity and decrease incidence of diabetes. The aim of our study was to assess the significance of adipose tissue in blood pressure-lowering and metabolic effects of ACE-inhibitor ramipril.

Materials and methods: We studied metabolic and blood pressure-lowering effects of ACE inhibitor ramipril in severely insulin resistant and diabetic lipotrophic A-ZIP/F-1 mice which lack white adipose tissue and in C57BL/6J mice with high fat diet (HFD)-induced obesity and insulin resistance. Blood glucose, circulating levels of insulin and other hormonal parameters were measured by commercial RIA and ELISA kits and mRNA expression of selected adipokines in subcutaneous (SAT) and visceral adipose tissue (VAT) was measured by real time PCR.

Results: Three months of treatment with ramipril (8 mg/kg in the food) did not significantly affect blood glucose, serum insulin, triglycerides or free fatty acids in A-ZIP mice but it partially prevented the increase of body fat content, decreased adipocyte size, free fatty acids (1239.95 ± 97.89 vs 597.88 ± 73.89 μ M, $p < 0.05$) and triglyceride (12.54 ± 1.02 vs 6.79 ± 0.56 mg/dl, $p < 0.05$) levels and improved insulin sensitivity as measured by insulin concentrations (1.73 ± 0.3 vs 0.60 ± 0.1 ng/ml, $p < 0.05$) and HOMA index (0.77 ± 0.12 vs 0.31 ± 0.05 , $p < 0.05$) in HFD-fed C57BL/6J mice. In subcutaneous fat, ramipril treatment prevented a decrease of adiponectin mRNA expression induced by HFD and tended to decrease mRNA expression of macrophage marker Emr1 and TNF- α . In visceral adipose tissue, ramipril prevented a decrease of adiponectin mRNA expression induced by HFD, significantly blunted increased Emr1 and MCP-1 and tended to decrease interleukin-6 and TNF- α mRNA expression. Mean arterial blood pressure (MABP) in A-ZIP mice was significantly higher compared to C57BL/6J mice. Ramipril treatment decreased MABP in both A-ZIP (96 ± 6.0 vs 71 ± 4.0 Torr, $p < 0.05$) and C57BL/6J mice (72 ± 3 vs 62 ± 4 Torr, $p = 0.122$). **Conclusion:** ACE inhibition by ramipril partially prevented the development of obesity and insulin resistance in mice fed HFD while it did not affect insulin sensitivity in fatless A-ZIP mice. In contrast, blood pressure-lowering effect of ramipril was present in both control and fatless A-ZIP mice. We conclude that while insulin-sensitizing effects of ACE-inhibition require the presence of adipose tissue its blood pressure-lowering effects are independent of the presence of fat.

Dietary trans fatty acids are associated with impaired endothelial function in type 2 diabetic patients, independently of other cardiovascular risk factors

T. Zelmanovitz¹, T. Weiss¹, A.L.T. dos Santos¹, C. Kümmel Duarte¹, F. dos Santos de Oliveira¹, J.L. Gross¹, L.E.P. Rohde², M.J. de Azevedo¹;

¹Endocrinologia, ²Cardiologia, Hospital de Clínicas de Porto Alegre, Brazil.

Background and aims: There has been a growing interest in the role of nutritional factors, especially the fatty acids intake, in modulating endothelial function. Few studies analyze the association between dietary fatty acid composition and vascular function in diabetic patients, and most of them evaluated only their acute effects on endothelial function. This cross-sectional study aimed to evaluate the possible association between dietary fatty acid composition and impairment of endothelial function measured by flow-mediated dilatation (FMD) of type 2 diabetic patients.

Materials and methods: The nutritional evaluation consisted of completing 3-day weighed diet records (WDR). Compliance with the WDR was evaluated by protein intake confirmed by 24-h urinary urea. Clinical evaluation consisted of metabolic and blood pressure control, detection of chronic complications of DM and cardiovascular evaluation. The patients underwent assessment of endothelium-dependent FMD of the brachial artery to evaluate endothelial function.

Results: Eighty-four patients were evaluated (age:63±9 years;64%male) and the observed median endothelium-dependent FMD was 5.55% (1.19–20.10). In multiple linear regression analyses, log-transformed FMD (dependent variable) was inversely associated to dietary trans fatty acids (TFA) intake (β -Standardized Coefficients = -0.387; $P=0.001$; $R^2=0.271$, $P=0.001$), and to the presence of diabetic nephropathy (β -Standardized Coefficients = -0.235; $P=0.04$), adjusting to systolic blood pressure, adequacy of WDR, gender and waist circumference. In a multivariate logistic regression analysis, lower FMD (median FMD < 5.55 %; dependent variable) was positively associated with dietary TFA intake (Odds Ratio (OR)=7.89; 95%Confidence Interval (CI):1.85–33.7; $P=0.005$) and presence of diabetic nephropathy (OR = 4.77; 95%CI:1.37–16.6; $P=0.014$), after adjusting for covariates.

Conclusion: In patients with type 2 diabetes, a higher intake of TFA is inversely associated with endothelial function assessed by ultrasound of the brachial artery, independently of other cardiovascular risk factors.

Nonfasting blood concentration of lipoprotein subfractions and risk of coronary heart disease in a Swedish nested case-control study

E. Sonestedt¹, S. Chiu², O. Melander¹, M. Orho-Melander¹, R.M. Krauss²;

¹Department of Clinical Sciences, Lund University, Malmö, Sweden,

²Children's Hospital Oakland Research Institute, USA.

Background and aims: The ion mobility method is unique in its capability for directly determining concentrations of the full spectrum of lipoprotein particles, from small HDL to large VLDL, as a function of their particle size. Several studies have shown significant associations between nonfasting lipid levels and risk of cardiovascular disease, but the evidence of association between nonfasting lipoprotein subfractions and cardiovascular risk is limited. The aim of this project was therefore to examine the association between plasma concentration of lipoprotein subfractions and risk of coronary heart disease.

Materials and methods: Plasma lipoprotein subfractions were measured with the ion mobility method in 1575 subjects (45–74 years) from the Malmö Diet and Cancer cohort that during 12 years of follow-up were diagnosed with incident coronary heart disease and 1570 controls matched by sex and age.

Results: After adjusting for potential confounders, the highest versus lowest quintile of very small LDL (OR, 1.28; 95% CI, 1.02–1.61; P -trend, 0.008), small LDL (OR, 1.68; 95% CI, 1.33–2.12; P -trend, <0.001) medium LDL (OR, 1.54; 95% CI, 1.22–1.93; P -trend, <0.001), large IDL (OR, 1.26; 95% CI, 1.00–1.58; P -trend, 0.008) and VLDL (OR, 1.25; 95% CI, 1.00–1.58; P -trend, 0.006) was associated with higher risk of coronary heart disease, while no significant association was observed for large LDL (P -trend, 0.66) and small IDL (P -trend, 0.76). In addition, large HDL (OR, 0.57; 95 % CI, 0.44–0.73; P -trend, <0.001), but not small HDL (P -trend, 0.71), was associated with decreased risk.

Conclusion: In this prospective study measuring lipoprotein subfraction particle concentration in nonfasting blood, high concentrations of small and medium LDL particles and low concentration of large HDL particles showed the most predictive associations with coronary heart disease.

Antibodies towards HDL components in type 2 diabetes patients are associated with modifications in the anti-atherogenic properties of HDL

J.R. Bataca¹, I. Ferreira², C. Favas^{3,2}, M. Amaral^{1,2}, J. Delgado Alves^{1,4};

¹CEDOC -Farmacologia, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, ²Serviço de Medicina IV, Hospital Fernando da Fonseca,

³Serviço de Medicina II, Hospital Curry Cabral, Lisboa, Portugal, ⁴Serviço de Medicina IV, Hospital Fernando da Fonseca, Lisbon, Portugal.

Background and aims: Type 2 diabetes is primarily a metabolic disorder, with a major vascular involvement. In patients with type 2 diabetes, the risk of developing atherosclerosis at an earlier age is three-to fivefold greater than in nondiabetics after controlling for other risk factors. Anti-atherogenic properties of HDL are well recognised: they prevent the oxidative modification of LDL and its consequent uptake by monocytes and inhibits cytokine-induced adhesion molecule production. We have previously identified anti-HDL (aHDL) antibodies in different medical conditions and associated them with changes in the anti-oxidant and anti-inflammatory properties of HDL. This study was undertaken to determine the presence of antibodies directed against different components of HDL in type 2 diabetes patients and establish a possible relationship between these antibodies and the anti-oxidant and anti-inflammatory properties of HDL.

Materials and methods: Thirty five type 2 diabetes patients were compared with an age and sex-matched control. IgG antibodies against HDL, apolipoproteins (Apo A-I, A-II and C-I) and paraoxonase 1 (PON1) were determined by ELISA, as was vascular and intercellular adhesion molecules (VCAM-1 and ICAM-1). Plasma lipid profile was determined by standard enzymatic techniques. PON 1 activity was assessed by quantification of nitrophenol formation. Nitric oxide metabolites (NOx) were measured by Griess reaction.

Results: Patients with type 2 diabetes had higher titres of IgG aHDL ($p<0.0001$), aApo A-I ($p=0.005$), and aPON ($p<0.0001$) antibodies, lower

PON1 activity ($p<0.0001$) and mean levels of HDL ($p=0.0003$) and increased levels of VCAM-1 ($p=0.037$), ICAM-1 ($p=0.018$) and NOx ($p=0.014$) than healthy controls. There was no difference in aApo A-II and aApo C-I antibodies. IgG aHDL antibodies directly correlated with aApo A-I ($p=0.022$), and aPON1 ($p=0.006$) levels. aApo A-I and aPON1 antibodies were associated with a decreased PON1 activity ($p=0.023$ and $p=0.004$) and increased endothelial dysfunction assessed by VCAM-1 ($p=0.005$ and $p=0.023$), ICAM-1 ($p=0.004$ and $p=0.002$) and NOx ($p=0.028$ and $p=0.007$).

Conclusion: In this study, IgG aHDL, aApo A-I and aPON1 antibodies were shown to be present in in type 2 diabetes, with no clinical features of autoimmune disease. These results suggest that aHDL antibodies might be a “family” of auto-antibodies of which Apo A-I and PON1 seem to be the main targets. These antibodies are associated with lower PON1 activity and higher VCAM-1, ICAM-1 and NOx and may contribute to the pathogenesis of atherosclerosis.

Comparison of lipid variables to predict cardiovascular disease in Japanese hypercholesterolaemic patients with and without type 2 diabetes mellitus

H. Sone¹, R. Nishimura², T. Nakagami³, N. Tajima², MEGA Study Group; ¹Endocrinology and Metabolism, University of Tsukuba Institute of Clinical Medicine, Mito, ²Internal Medicine, Jikei University School of Medicine, Tokyo, ³Tokyo Womens' Medical University, Japan.

Background and aims: The several lipid variables and their ratios have been suggested to be predictive of CVD in patients with and without diabetes mellitus (DM), few studies have compared these variables directly in these patients, especially in Asia.

Materials and methods: We compared the relationship between CVD and various lipid variables (low-density lipoprotein cholesterol [LDL-C], high-density lipoprotein cholesterol [HDL-C], non-HDL-C [NHDL-C], the ratio of LDL-C to HDL-C [LDL-C/HDL-C], the ratio of total cholesterol (TC) to HDL-C [TC/HDL-C]), and triglycerides (TG) in 3,170 hypercholesterolemic Japanese patients with and without DM in the diet alone group of the large-scale MEGA Study. DM was defined as a baseline fasting glucose ≥ 7.0 mmol/L, HbA1c $\geq 6.1\%$, or taking an oral hypoglycemic agent. DM ($n=2,502$) and non-DM ($n=668$) patients were divided by tertiles according to their baseline data for each lipid variable to compare the incidence of CVD, defined as coronary heart disease (CHD) plus stroke in the two groups. The hazard ratios (HR) and 95% confidence intervals (95% CI) were estimated by the Cox proportional hazard model.

Results: The Table summarizes the HR for CVD against the lowest risk tertile for each lipid parameter. The LDL-C/HDL-C and TC/HDL-C ratios were markedly and significantly higher in the highest tertile of non-DM (2.82 and 2.54, respectively) and in the middle tertile of DM patients (3.11 and 2.78, respectively). In non-DM patients, NHDL-C was associated with a significant 2.68 higher risk for CVD.

Conclusion: The best predictor of CVD in DM and non-DM Japanese hypercholesterolemic patients is the LDL-C/HDL-C and TC/HDL-C ratios.

Hazard ratios for CVD according to tertiles of various lipid variables (* $p<0.05$)

		LDL-C	HDL-C	TG	TC/HDL-C	LDL-C/ HDL-C	NHDL-C
Non DM	Tertile (low)	1	2.29*	1	1	1	1
	Tertile (middle)	1.31	1.59	1.10	1.94	2.01	1.82
	Tertile (high)	1.79	1	1.45	2.54*	2.82*	2.68*
DM	Tertile (low)	1	2.18	1	1	1	1
	Tertile (middle)	1.56	2.37*	1.13	2.78*	3.11*	0.97

Background and aims: Recent reports suggest apolipoprotein (apo) B is a good predictor of coronary risk. Low density lipoprotein cholesterol (LDL-C) may underestimate the number of atherogenic particles in certain patients with elevated levels of small dense LDL particles and remnant particles. To this end, the ADA/ACC treatment guidelines for cardiometabolic patients, including patients with diabetes, recommend apo B targets <0.9 g/L and <0.8 g/L for high risk and very high risk patients, respectively.

Materials and methods: This was a pooled analysis of 27 previously published, randomized, double-blind, active or placebo-controlled clinical trials conducted in 21794 adult patients (age range: 18–81 yr) with elevated LDL-C (range: 1.81–6.48 mmol/L) receiving ezetimibe (EZE)/statin or statin alone for 4 to 24 wk. Simple linear regression analyses were employed to calculate average LDL-C levels corresponding to apo B values of 0.9 g/L at baseline (i.e., in drug-naïve or statin-treated patients) and following treatment with EZE/statin or statin alone in subgroups of patients with/without hypertriglyceridemia (i.e., baseline TG $<$ and >2.26 mmol/L) and diabetes (either type 1 or 2).

Results: In diabetes and non-diabetes patients, LDL-C was highly correlated with apo B at baseline and correlations improved after treatment with EZE/statin and statin. At baseline in drug-naïve patients, the predicted LDL-C values, assuming an apo B=0.9 g/L, were close to the recommended treatment goals for high-risk patients (i.e., 2.59 mmol/L). At baseline in statin-treated patients and in both statin and drug-naïve patients following treatment with EZE/statin or statin alone, the predicted LDL-C values were closer to the more intensive recommended treatment goal (i.e., 1.81 mmol/L). In general, diabetes patients had lower predicted LDL-C values than non-diabetes patients irrespective of whether they were taking lipid-modifying drugs at baseline or not. When the linear regression analyses were examined by baseline TG, the predicted LDL-C values, assuming an apoB value of 0.9 g/L, were consistently lower in hypertriglyceridemic compared with normotriglyceridemic patients irrespective of diabetes status (data not shown).

Conclusion: Compared to non-diabetes patients, more aggressive LDL-C goals should be achieved in diabetes patients receiving lipid-lowering therapy to normalize apo B-containing lipoproteins.

Untreated at baseline or on treatment at endpoint	Population	N	Apo B:LDL-C Pearson Correlation Coefficient (R^2)	Predicted LDL-C corresponding to apo B=0.9 g/L

Anti-inflammatory and anti-oxidant properties of high density lipoproteins (HDL) are impaired in type 2 diabetesC. Morgantini^{1,2}, A. Natali³, B. Boldrini², S. Imaizumi³, M. Navab³, A. Fogelman³, E. Ferrannini², S. Reddy³;¹Scuola Superiore Sant'Anna, Pisa, ²Internal Medicine, University of Pisa, Italy, ³Medicine/Cardiology, University of California Los Angeles, USA.

Background and aims: Despite achieving recommended targets of serum cholesterol, blood pressure and glycaemia, type 2 diabetic (T2D) patients remain at high risk of vascular events; other factors must therefore be involved in this residual risk. Recent evidence suggests that the athero-protective role of HDL depends not only on their plasma concentration but also on their anti-inflammatory and anti-oxidant properties. In the present work, we sought to determine whether HDL function is impaired in T2D and whether *ex vivo* treatment with L-4F, an ApoA-I mimetic peptide, could improve HDL function.

Materials and methods: HDL was separated by FPLC from 93 T2D patients and 31 healthy subjects. The anti-inflammatory function of HDL was determined by measuring the ability of HDL to inhibit LDL-induced monocyte chemotactic activity in cultured human aortic endothelial cell monolayers. HDL inflammatory index (HII) was calculated as the monocyte migration induced by standard LDL (sLDL) in the presence of test HDL normalized for the value obtained with sLDL alone. The HDL anti-oxidant properties were measured by the cell-free assay (as the ratio between dichlorofluorescein diacetate fluorescence of HDL+sLDL vs sLDL alone) and also by HDL spontaneous fluorescence. In subgroups of patients and controls, HII was repeated after incubation with L-4F, and Liquid Chromatography-Mass Spectrometry measured the HDL content of 5 oxidized fatty acids.

Results: The mean HII was 1.42 ± 0.29 in diabetic subjects and 0.70 ± 0.19 in controls ($p < 0.001$). HDL anti-oxidant properties estimated either by the cell-free assay (2.03 ± 1.35 vs 1.60 ± 0.80 , $p < 0.05$) or with HDL spontaneous fluorescence (1708 ± 739 vs 1233 ± 601 rfu, $p < 0.001$) were impaired in T2D patients when compared with healthy subjects. HII correlated with spontaneous HDL fluorescence ($r = 0.23$) and with serum Lp(a) concentration ($r = 0.23$). *Ex-vivo* treatment of plasma with L-4F restored HDL anti-inflammatory activity in T2D (1.26 ± 0.17 vs 0.71 ± 0.11 after treatment, $p < 0.001$) and while only marginally improving it in healthy subjects (0.81 ± 0.16 vs 0.66 ± 0.10 after treatment, $p < 0.05$). Each and all the measured oxidized fatty acids in HDL were much higher (from 18 to 63 fold) in T2D patients than in controls.

Conclusion: In patients with T2D, the anti-inflammatory and anti-oxidant activities of HDL are severely impaired. L-4F, an ApoA-I mimetic peptide, *ex vivo* significantly improved HDL function; this novel approach might therefore result useful in the prevention of cardiovascular diseases in T2D.

The effect of increased body fat accumulation on cardiometabolic risk factors in type 1 diabetes patients

R. Lichiardopol, A. Florentiu;

Clinic 1 of Diabetes, Nutrition and Metabolic Diseases, "N.C. Paulescu" Institute, Bucharest, Romania.

Background and aims: Increased body fat accumulation associated to increased prevalence of cardiometabolic risk factors is a frequent encounter and characterizes a "metabolically abnormal" phenotype of body fat increase in type 2 diabetes patients. Less data are available regarding the metabolic consequences of body fat accumulation in type 1 diabetes patients. The aim of this study was to evaluate the effects of increased fat accumulation in a group of type 1 diabetes patients.

Materials and methods: Clinical, biochemical and body composition data (using a bioimpedance analyzer) were compared across body fat mass (BFM) distribution tertiles in a group of one hundred and two (31 males, 71 females) consecutive type 1 diabetes patients. Data are presented as mean (SD) value. An EpiInfo software was used for statistical analysis. A p value < 0.05 was significant.

Results: There were no significant differences in BMI between males and females. As compared to the first tertile, the patients in the third tertile (T3) of BFM distribution had greater BMI [$29.5(2.9)$ vs $22.6(2.3)$ Kg/m²; $p < 0.0001$], BFM [$30.7(6.0)$ vs $14.1(3.9)$ Kg; $p < 0.0001$], estimated visceral (eVFA) fat area [$135.5(27.7)$ vs $79.3(22.1)$ cm²; $p < 0.0001$], waist circumference [$95.1(9.2)$ vs $80.0(7.3)$ cm; $p < 0.0001$] and disease duration [$16.9(9.6)$ vs $9.2(9.0)$ yrs;

$p < 0.002$] but no significant differences regarding age [$45.5(16.9)$ vs $43.7(14.7)$ yrs; $p = 0.63$], HbA1c [$9.0(1.9)\%$ vs $9.6(2.7)\%$; $p = 0.48$], serum uric acid [$3.5(1.5)$ vs $3.5(1.9)$ mg/dl; $p = 0.97$], plasma HDL-cholesterol [$53.0(15.0)$ vs $53.6(15.7)$ mg/dl; $p = 0.88$] and triglycerides [$98.4(50.2)$ vs $130.9(145.5)$ mg/dl; $p = 0.48$]. The prevalence of macrovascular complications (20.0% vs 18.2%; $p = 0.83$) was not different between groups. In logistic regression, macrovascular complications were significantly related to age but not to BFM or eVFA. The prevalence of hypertension (51.5% vs 32.1%; $p = 0.13$) and of microvascular complications (54.5% vs 31.8%; $p = 0.097$) were greater in T3 group but the differences did not reach statistical significance. In logistic regression, the prevalence of microvascular complications was related to disease duration but not to BFM or eVFA.

Conclusion: Our data suggest that increased weight and fat accumulation in type 1 diabetes patients is not associated with increased prevalence of cardiometabolic risk factors and macrovascular complications.

687

Lipids seasonal variability in type 2 diabetes

G. Bardini, S. Giannini, I. Dicembrini, C.M. Rotella;

Section of Endocrinology, Department of Clinical Pathophysiology, University of Florence, Italy.

Background and aims: Previous studies conducted in healthy volunteers and in patients with coronary heart disease showed seasonal variation in lipid levels, with higher cholesterol levels in fall and winter than in spring and summer. No data were reported for diabetic patients. The aim of the study was to evaluate the seasonal variability of lipids in type 2 diabetic patients (DM2).

Materials and methods: In a retrospective study a group of 302 (183 F, 119 M) DM2 outpatients, aged 64.5 ± 9.0 yrs, were consecutively evaluated for two years during fall/winter (F/W) and spring/summer (S/S). All patients studied had unmodified lipid and hypoglycaemic drug therapies and, when present, the insulin doses were not changed by $> 10\%$ throughout the observation. In all patients, we collected anthropometrical indices, HbA1c, and lipid profile: total cholesterol (TC), high density lipoprotein (HDL-C), triglycerides (Trg), low-density lipoprotein (LDL-C) and non-HDL (non-HDL-C).

Results: The outpatients showed HbA1c $7.1 \pm 0.8\%$ with 6.6 ± 5.5 yrs duration of diabetes. 89.0% assumed metformin (Met), 7.4% thiazolidinediones, 30.2% sulphonylureas, 28.2% Met+SU in association and 11.4% were insulin treated. Among patients studied, 62.4% were currently treated with hypertensive drugs and 45% with statins. During the four periods of collection data, HbA1c levels showed seasonal variability with median 6.82% in F/W and 6.6% in S/S, without statistical significance. Instead, a statistically significant seasonal difference was observed for lipids, with the higher median levels in F/W than in S/S, both in patients without or under statin treatment. In particular, median TC levels in F/W were 196.5 mg/dl vs 189 mg/dl ($p < 0.001$) in subjects without statins and 167 mg/dl vs 165 mg/dl ($p < 0.05$) in patients with statins ($p < 0.05$). Median LDL-C levels observed were 120 mg/dl in F/W vs 111 mg/dl in S/S ($p < 0.001$) without statins and 88.7 mg/dl vs 86.5 mg/dl with statins ($p < 0.05$). A significant increase between F/W and S/S of HDL-C levels was observed only in males both without (42.5 mg/dl vs 44 mg/dl; $p < 0.001$) and with statin therapy (40 mg/dl vs 42 mg/dl; $p < 0.05$), respectively. Higher significant median Trg levels were observed in F/W versus S/S, showing 128.5 mg/dl vs 125 mg/dl ($p < 0.05$) for untreated patients and 126 mg/dl vs 123 mg/dl ($p < 0.05$) in patients with statins. Median non-HDL-C levels were also significantly elevated in F/W vs S/S: 145 mg/dl vs 137 mg/dl ($p < 0.001$) for untreated subjects and 114 mg/dl vs 110 mg/dl ($p < 0.001$) in patients with statins. When lipid targets were examined by seasons, rates of achievement were greater in S/S than F/W. In fact, the target of LDL-C < 100 mg/dl was reached by 27% patients in S/S vs 23.3% in F/W in the group without statins ($p < 0.05$) and by 70.7% vs 67% with statin therapy ($p < 0.05$). The target of non-HDL-C < 130 mg/dl was achieved by more subjects in S/S than in F/W only for patients with statins (51.6% vs 34%; $p < 0.001$). Moreover, Trg levels < 150 mg/dl were reached by more patients in S/S than in F/W: 75% vs 70% without lipid therapy, 73% vs 68% with statins and 66.7% vs 50% with other lipid drugs ($p < 0.001$, for all).

Conclusion: In DM2 clinical outpatients, for the first time, we observed a seasonal variability of lipids, with a peak in fall/winter and nadir in spring/summer. These data could suggest a less aggressive lipids treatment during the warmer seasons in order to increase the compliance of DM2 patients to the multitherapy.

Low to moderate amounts of sugar sweetened beverages impair glucose and lipid metabolism, including beta-oxidation of fatty acids, in healthy young men - a randomised controlled trial

M. Hochuli¹, I. Aeberli², P.A. Gerber¹, H. Troxler³, S. Kohler¹, S. Haile⁴, I. Gouni-Berthold⁵, H. Berthold⁶, G. Spinass¹, K. Berneis¹;

¹Division of Endocrinology, Diabetes and Clinical Nutrition, University Hospital, Zurich, ²Institute of Food, Nutrition and Health, Federal Institute of Technology (ETH), ³Clinical Chemistry Laboratory, University Children's Hospital, ⁴Division of Biostatistics, Institute for Social and Preventive Medicine, Zurich, Switzerland, ⁵Department of Internal Medicine II, Cologne, ⁶Lipid Clinic at the Interdisciplinary Metabolism Center, Charité University Medicine, Berlin, Germany.

Background and aims: Sugar-sweetened beverages (SSB) have unfavorable effects on glucose and lipid metabolism if consumed in high quantities by obese subjects but the effect of lower doses in normal weight subjects is less clear. The aim was to investigate the effects of SSB, consumed in small to moderate quantities for three weeks on LDL particle distribution, acylcarnitine profiles and other parameters of glucose and lipid metabolism in healthy young men.

Materials and methods: 29 subjects were studied in a prospective, randomized, controlled cross-over trial. Six three-week interventions were assigned in random order: (1-5) 600 ml SSB containing 40 or 80 g of fructose (medium/high fructose, MF/HF), or glucose per day (medium/high glucose, MG/HG) or 80 g of sucrose per day (high sucrose, HS); (6) dietary advice to consume low amounts of fructose (LF). Outcome parameters were measured at baseline and after each intervention. In addition, fasting acylcarnitine profiles were measured by mass spectrometry in a second group of 9 subjects undergoing the same interventions.

Results: LDL-particle size was reduced after HF by -0.51nm (95% CI -0.19 to -0.82nm) and after HS by -0.43nm (-0.12 to -0.74 , $p<0.05$ for both). Similarly, a more atherogenic LDL subclass distribution was seen when fructose containing SSB were consumed (MF, HF and HS, $p<0.05$). Fasting glucose increased significantly after all interventions (4-9%, $p<0.05$). Levels of long- and also medium-chain fasting acylcarnitines were increased after fructose and sucrose diets (HF, MF and HS), compared to glucose (HG) diets (e.g. C18 acylcarnitines HF $2.38\text{ }\mu\text{mol/l}$ vs HG 1.81 ; C10-C18 acylcarnitines HF $4.95\text{ }\mu\text{mol/l}$ vs HG 3.62 , C16 (palmitoylcarnitine) HF $1.43\text{ }\mu\text{mol/l}$ vs HG 0.96 ; all $p<0.05$).

Conclusion: The present data clearly demonstrate potentially harmful effects of low to moderate consumption of SSB on markers of cardiovascular risk such as LDL particles and fasting glucose. Analysis of acylcarnitine profiles is performed for the first time in this setting and yields further insights into fatty acid metabolism, suggesting impaired beta-oxidation of fatty acids after fructose containing diets.

Supported by: Swiss National Science Foundation

the group of T2D patients, plasma rbp4 was correlated positively with triglycerides ($r=0.74$, $p=0.003$), apoB VLDL pool ($r=0.62$, $p=0.017$) and negatively with VLDL-apoB FCR ($r=-0.66$, $p=0.001$) whereas these association were not found in the group of normal subjects. In the diabetic population rbp4 level explained 44% of VLDL-apoB FCR variance and the strong negative association between plasma rbp4 and VLDL-apoB FCR was independent of age, gender, glycemia or BMI.

Conclusion: 1) Our kinetic study has shown, in T2D patients, but not in normal subjects, a strong negative correlation between plasma rbp4 and VLDL-apoB FCR. This can explain the positive correlation between plasma rbp4 and triglycerides, in T2DM. 2) These data suggest that rbp4 may be involved in the pathophysiology of hypertriglyceridemia in T2DM by reducing VLDL catabolism.

Retinol binding protein 4 (rbp4) is a significant determinant of VLDL catabolism in patients with type 2 diabetes

B. Vergès^{1,2}, L. Duvillard^{3,2}, P. Buffier¹, B. Bouillet¹, M.-C. Brindisi¹, J.-M. Petit^{1,2};

¹Endocrinology, Diabetology, Hôpital du Bocage, CHU Dijon, ²INSERM CRI 866, ³Biochemistry, Hôpital du Bocage, CHU Dijon, France.

Background and aims: Plasma levels of the adipokine retinol binding protein 4 (rbp4), that are elevated in patients with type 2 diabetes, have been shown to be positively correlated with triglycerides. However, so far, the association between rbp4 and triglyceride metabolism remains unknown. This prompted us to perform a study in order to analyse the association between plasma rbp4 and apoB-containing lipoproteins.

Materials and methods: An *in vivo* kinetic study with stable isotopes (¹³C-leucine) was performed in 34 subjects including 14 patients with type 2 diabetes (T2D) and 20 normal individuals. Plasma rbp4 was measured by ELISA.

Results: Plasma rbp4 levels were significantly higher in T2D patients than in normal subjects (41.6 ± 15.9 vs. $31.3 \pm 10.1\text{ }\mu\text{g/ml}$, $p<0.05$). In the whole studied population, plasma rbp4 was correlated positively with triglycerides ($r=0.61$, $p<0.001$), apoB VLDL pool ($r=0.60$, $p<0.001$) and negatively with VLDL-apoB Fractional Catabolic Rate (FCR) ($r=-0.39$, $p=0.025$). No association was found between plasma rbp4, on the one hand, and VLDL-apoB production rate, apoB-IDL or LDL kinetic parameters, on the other hand. In

Central role of lipoprotein lipase and very low-density-lipoprotein receptor on macrophage foam cell formation by triglyceride-rich lipoproteins and low density lipoprotein

T. Sadao, Y. Zenimaru, M. Imagawa, T. Kimura, J. Suzuki, I. Miyamori; University of Fukui, Japan.

Background and aims: Dyslipidemia is a common feature of diabetes and is related to cardiovascular disease. Triglyceride-rich lipoproteins (TGRLs) and low-density-lipoprotein (LDL) cholesterol are independent risk factors for coronary artery disease. VLDL receptor (VLDL-R) is a member of the low-density-lipoprotein receptor (LDL-R) family. VLDL-R binds and internalizes TGRLs with high specificity and is not down regulated by sterols. VLDL-R was expressed abundantly in fatty acids active tissues (heart, skeletal muscle and fat), brain and macrophages. In macrophages, VLDL-R is one of the candidate receptors for the foam cell formation by TGRLs, and macrophage cells itself secrete apolipoprotein (apo) E and lipoprotein lipase (LPL). We have reported that the low affinity binding of fasted human VLDL to the VLDL-R could be overcome by enriching VLDL with either apoE or LPL. In this study, we investigated the role of apoE, LPL and VLDL-R on foam cell formation in macrophages.

Materials and methods: We used human THP-1 macrophages and human monocyte-derived macrophages because there is no VLDL-R protein in mouse macrophages. Northern- and Western-blot were used to examine the expression of apoE, LPL and VLDL-R. LPL protein levels in medium were also measured. To check the foam cell formation by TGRLs in macrophages, oil-red stain was used. 125 I-lipoprotein binding study was also examined.

Results: Beta-VLDL (TGRLs) and oxidized LDL but not native LDL induced foam cell formation in macrophages. During macrophage differentiation, the expression of VLDL-R, LPL, apoE and type A scavenger receptor made an appearance, and the expression of LDL-R was decreased. Interferon-gamma (IFN- γ) inhibited the VLDL-R and LPL expression in a dose- and time-dependent manner. The apoE and LDL-R expression were not changed by IFN- γ . IFN- γ inhibited the foam cell formation by TGRLs in parallel. Furthermore small interfering (Si) RNA of VLDL-R or LPL and anti-LPL monoclonal antibody (5D2) decreased the foam cell formation by TGRLs. Using VLDL-R over-expressing IdLA-7 CHO cells (LDL-R deficient CHO cells), we showed that native LDL that is not recognized by VLDL-R was taken up by the VLDL-R when native LDL was incubated with LPL. The effect of LPL on the up-take of LDL by the VLDL-R was decreased by heparinase treatment (graph).

Conclusion: It is likely that VLDL-R is functioning in concert with LPL in macrophages for the uptake of both TGRLs and native LDL. Surprisingly native LDL particles are recognized by VLDL-R when LDL is modified by LPL. Inhibition of LPL or VLDL-R expression may attenuate an early atherosclerosis in diabetes by TGRLs and LDL.

Plasma phospholipid transfer protein activity is independently determined by obesity and insulin resistance

R.P.F. Dullaart¹, R. de Vries¹, P.J.W. Kappelle¹, G.M. Dallinga-Thie²;

¹Endocrinology, University Medical Center, Groningen, ²Vascular and Experimental Vascular Medicine, University Medical Center, Amsterdam, Netherlands.

Background and aims: Phospholipid transfer protein (PLTP) is an emerging cardio-metabolic risk factor which is intricately involved in lipoprotein metabolism. Elevated plasma PLTP activity levels have been reported in diabetes mellitus and obesity, but the relative contributions of obesity and insulin resistance to plasma PLTP activity remain unclear. We tested whether plasma PLTP activity is independently related to (central) obesity and insulin resistance in non-diabetic subjects.

Materials and methods: The relationships of plasma PLTP activity levels (phospholipid vesicles-HDL system) with waist circumference, waist/hip ratio, BMI and insulin resistance (homeostasis model assessment (HOMA_{ir})) were determined in 313 non-diabetic subjects (273 men).

Results: PLTP activity was higher in 67 subjects with enlarged waist circumference (NCEP-ATP-III criteria; 102±11 AU) compared to 246 subjects with normal waist (98±11 AU, P=0.027). In univariate analysis PLTP activity correlated positively with BMI (r=0.125), waist (r=0.188), waist/hip ratio (r=0.143) and HOMA_{ir} (r=0.192) (p<0.05 to p<0.001). In age- and sex-adjusted multiple linear regression models, waist circumference (β=0.158, p=0.025) but not BMI (P=0.55) predicted PLTP activity independently of HOMA_{ir} (β=0.126, p=0.047). Additionally, both waist circumference and waist/hip ratio interacted positively with HOMA_{ir} on PLTP activity (β=0.109, p=0.056 and β=0.156, p=0.034, respectively). The interaction of waist circumference with HOMA_{ir} on PLTP activity is shown in the Figure.

Conclusion: In non-diabetic subjects, both (central) obesity and insulin resistance influence plasma PLTP activity, resulting in further elevated plasma PLTP activity with increasing obesity and insulin resistance. Higher PLTP activity could contribute to elevated cardiovascular risk attributable to obesity and insulin resistance.

Figure: Graphical presentation of the interaction between waist circumference and insulin resistance on plasma PLTP activity

Cholesterol-lowering effects of metformin in APOE*3-Leiden.CETP mice, a transgenic model with a human-like lipoprotein profile

B. Guigas¹, J.J. Geerling², G.C.M. van der Zon¹, A.M. van den Hoek³, H.M. Princen³, L.M. Havekes^{2,3}, P.C.N. Rensen²;

¹Dept. of Molecular Cell Biology, Leiden University Medical Center,

²Dept. of Endocrinology and Metabolic Diseases, Leiden University Medical Center,

³Gaubius Laboratory, Netherlands Organization for Applied Scientific Research-Quality of Life, Leiden, Netherlands.

Background and aims: Metformin is one of the most widely used antidiabetic drugs in the treatment of type 2 diabetes. On top of its anti-hyperglycemic properties, metformin also lowers plasma very low-density lipoprotein

(VLDL) in type 2 diabetes patients by a mechanism that remains to be elucidated. The aim of this study was to investigate the effects and underlying molecular mechanisms of metformin on VLDL metabolism in APOE*3-Leiden.CETP mice, a transgenic model characterized by a human-like lipoprotein profile.

Materials and methods: 3 months-old APOE*3-Leiden.CETP female mice were fed a Western-type diet containing 0.1% cholesterol for 4 weeks, followed by the same diet with or without metformin (250 mg/kg body weight/day) for 4 weeks. Body weight, food intake, plasma glucose, insulin, total cholesterol (TC), triglycerides (TG), phospholipids (PL) and free fatty acids (FFA) levels, and plasma lipoproteins profile were measured at week 0, 2 and 4. Hepatic VLDL-TG production and tissue-specific clearance of VLDL-like emulsion particles were determined at week 4.

Results: Metformin did not affect body weight, food intake and plasma glucose, insulin and FFA levels but significantly lowered plasma TC (-30% and -38% at week 2 and 4, respectively; $p < 0.05$) and TG (-28% and -29% at week 2 and 4, respectively; $p < 0.05$). The analysis of lipoproteins profile revealed that the cholesterol-lowering effects of metformin is mainly due to a decrease in VLDL (-37%) without obvious change in high-density lipoprotein (HDL) levels. Metformin did not affect hepatic VLDL-TG production rate and particle composition, suggesting that the drug might rather promote VLDL-TG clearance by peripheral tissues. Interestingly, metformin specifically increased VLDL-derived FA retention in brown adipose tissue after continuous infusion of radiolabeled VLDL-like emulsion particles (+58%; $p < 0.05$).

Conclusion: Metformin decreases plasma VLDL-TG levels in APOE*3-Leiden.CETP mice by a mechanism which does not involve change in hepatic VLDL production but apparently promotes VLDL clearance by brown adipose tissue.

Background and aims: The metabolic syndrome is characterized by the co-occurrence of several risk factors i.e. increased body weight (bw) and insulin resistance (IR) and at the same time adverse changes in plasma lipids as observed in diabetic dyslipidemia, with increased triglycerides and apoB-containing lipoproteins and decreased HDL. The aim was to investigate whether the APOE*3Leiden.CETP (E3L.CETP) mouse is a translational model for the metabolic syndrome.

Materials and methods: Male E3L.CETP mice were put on a high fat diet and fructose in drinking water for 12-16 weeks to induce diet-induced obesity and IR. Thereafter, the mice were treated with either rosiglitazone (3 and 11 mg/kg/d), liraglutide (0.2 mg/kg/d), HSD-1 inhibitor (0.1 mg/kg/d), resveratrol (75 mg/kg/d), fenofibrate (12 mg/kg/d), atorvastatin (10 mg/kg/d) or niacin (720 mg/kg/d) for 4 weeks. The effects on bw, plasma lipids and IR (via plasma glucose/insulin and/or hyperinsulinemic euglycemic clamps) were assessed.

Results: Dietary treatment resulted in a human-like lipoprotein profile with a TC/HDL-C ratio of 3-4. Anti-diabetic compounds rosiglitazone, liraglutide and HSD-1 inhibitor significantly decreased glucose and insulin levels or IR. Liraglutide and HSD-1 inhibitor also decreased bw. Established lipid-lowering compounds atorvastatin, fenofibrate and niacin, and resveratrol improved the dyslipidemia.

Conclusion: The data indicate that the E3L.CETP mouse is a good translational animal model combining all important features that underlie the metabolic syndrome and mimic the human response to clinically used treatments. We conclude that the E3L.CETP mouse is a promising model to investigate the effects of new drugs, alone or in combination, that affect IR and diabetic dyslipidemia.

Kupffer cells as mediators of the beneficial metabolic effects of thiazolidinediones

T.J.C. Delgado^{1,2}, N. Dedousis², J.G. Jones³, D.K. Scott², R.M. O'Doherty²; ¹CEDOC, Faculdade de Ciências Médicas, Lisbon, Portugal, ²Division of Endocrinology and Metabolism, University of Pittsburgh, USA, ³Center for Neurosciences and Cell Biology of Coimbra, Portugal.

Background and aims: Kupffer cells (KC), the liver resident macrophages, have been implicated in the pathogenesis of the hepatic inflammation, insulin resistance, and steatosis associated with obesity/T2DM. Thus, high fat feeding rapidly induces a M1 inflammatory profile in KC, and KC depletion is sufficient to prevent the hepatic insulin resistance and steatosis associated with high fat feeding. Of interest, thiazolidinediones (TZD) improve hepatic insulin sensitivity, but the mechanisms of action remain unclear. Here, we tested the hypothesis that the effects of TZD are associated with a suppression of high fat feeding induced M1 KC polarization.

Materials and methods: Male Wistar rats (200-220 g) were submitted to surgery for implantation of chronic indwelling catheters in the left common carotid artery. After recovery, animals were separated in 4 different study groups: Group 1. NC: Rats maintained on a normal chow diet (n=5); Group 2. HF/KC+: Rats maintained on a high fat custom diet (Tekland TD.96001, Harlan Laboratories, Madison, WI, USA) (n=3); Group 3. HF/Tro: HF diet-fed rats treated with 0.02% of the TZD Troglitazone (n=4); and finally Group 4. HF/KC-: HF-fed rats KC depleted by means of 3-4 day intra-carotid interval injection of 10 mg/kg bw Gadolinium (III) chloride (Sigma, St. Louis, MI, USA). Following 14 days of diet, all animals underwent an i.p. glucose tolerance test (2 mg glucose/g bw). KC depletion was evaluated by qRT-PCR quantification of F4/80 mRNA levels and KC polarization in liver samples was measured by macrophage-localized TNF- α Immunofluorescence detection.

Results: Our data demonstrate that HF/KC+ had reduced glucose tolerance and increased KC polarization compared to NC. High fat fed KC-depleted animals (HF/KC-) displayed improved glucose tolerance concomitant with decreased KC number. Finally, TZD treatment ameliorated glucose intolerance in HF rats and these effects were associated with markedly reduced KC M1 polarization (See Figure).

Conclusion: Our data indicate that KC are important targets and potential mediators of the hepatic insulin-sensitizing actions of TZD in the liver. Further studies involving the metabolic profiling of KC-depleted and TZD-treated overfed rats are necessary to validate our hypothesis.

Area under the curve (AUC) during an intraperitoneal glucose tolerance test (2.0 mg glucose/g bw) and percentage of activated KC (measured as percentage of TNF- α releasing macrophages detected by Immunofluorescence Microscopy) and total KC (measured as gene expression of F4/80, a transmembrane glycoprotein expressed in macrophages). Normal chow-fed rats correspond to NC (n=5). HF-fed rats treated with 0.02% Troglitazone correspond to HF + Tro (n=4). HF-fed KC-depleted rats correspond to HF KC- (n=5) and HF-fed rats correspond to HF KC+ (n=3). * $p < 0.05$, relative to NC; ** $p < 0.01$, relative to NC; Δ $p < 0.05$, relative to HF KC+ and $\Delta\Delta$ $p < 0.01$, relative to HF KC+.

Prep1 regulates hepatic lipogenesis through SHIP2-mediated AMPK inhibitionS. Cabaro¹, F. Oriente¹, S. Iovino¹, V. D'Esposito¹, A. Liotti^{1,2}, F. Blasi³, C. Miele¹, P. Formisano¹, F. Beguinot¹;¹DBPCM & IEOS-CNR, University of Naples Federico II, ²Department of Pharmaceutical Science, University of Salerno, ³IFOM (Firc Institute of Molecular Oncology), Milan, Italy.

Background and aims: Prep1 is a homeodomain transcription factor belonging to the TALE proteins, including also Pbx1, which plays an essential role in hematopoiesis, organogenesis and development. Prep1 forms transcriptionally active complexes with Pbx1 and regulates the activity of several genes. The Prep1 null mutation leads to embryonic death at a very early stage. However, Prep1 heterozygous (Prep1^{i/+}) mice, which express only 55–57% of protein, have a complex metabolic phenotype with at least two relevant features. One is the presence of smaller but otherwise normally structured islets with reduced fasting and post-loading plasma insulin levels. The second is increased insulin sensitivity in skeletal muscle and in liver which is accompanied by protection from streptozotocin-induced diabetes. In muscle decreased Prep1 levels are followed by an increase of the PGC1α/ Glut4 mediated glucose uptake. In liver, better insulin sensitivity is due to a reduced Shp1 tyrosine phosphatase expression followed by an increase of insulin signaling. Also triglyceride levels are significantly reduced in the liver of Prep1^{i/+} mice. However, the molecular mechanism by which Prep1 controls lipogenesis is unclear. In this study we have focused our attention on the role of Prep1 on the regulation of the triglyceride synthesis.

Methods and results: To study the lipogenesis in the liver of the Prep1 heterozygous mice, we have examined the expression of the lipogenic enzyme FAS (Fatty Acid Synthase) by real-time RT-PCR analysis. Hepatic expression of FAS is significantly decreased. Western Blot analysis have shown increased phosphorylation of PKCζeta, LKB1, AMPK and ACC, which may control FAS expression and triglyceride production in Prep1^{i/+} mice liver. mRNA and protein levels of the lipid phosphatase SHIP2, an inhibitor of PI3Kinase/ PKCζeta signaling, are reduced by 40% in the liver of Prep1^{i/+} mice. Consistent with these data, HepG2 (Human Hepatocarcinoma cell line) cells overexpressing Prep1 show increased triglyceride levels and FAS expression, while PKCζeta, LKB1, AMPK and ACC phosphorylation is strongly reduced. Moreover, SHIP2 levels are increased by 50%. Interestingly, overexpression of Pbx1 cDNA in HepG2 cells mimicked Prep1 triglyceride synthesis. At the opposite, Prep1^{HR1} mutant, which is unable to bind Pbx1, fails to elicit these effects. Chromatin IP experiments indicate that Prep1/Pbx1 complex can bind SHIP2 promoter region and regulate its expression.

Conclusion: These data suggest that Prep1/Pbx1 regulates hepatic triglyceride production by increasing SHIP2 levels and thereby inhibiting the PKCζeta/AMPK signaling.

Cross-talk between proteasome and autophagy plays a role in hepatic insulin resistance via endoplasmic reticulum stressT. Otoda¹, T. Takamura¹, H. Misu¹, H. Hayashi¹, T. Ota¹, M. Yamamoto², S. Iseki², S. Kaneko¹;¹Disease Control and Homeostasis, ²Histology and Embryology, Kanazawa University Graduate School of Medical Science, Japan.

Background and aims: Insulin resistance is a key feature of people with type 2 diabetes (T2D). Growing evidence has suggested that accumulation of endoplasmic reticulum (ER) stress in the liver is a major contributor to insulin resistance; however, the molecular mechanisms linking diabetes and ER stress are not fully understood. In the last meeting (46th EASD Annual Meeting), we reported that proteasome dysfunction is observed in the liver of a mouse model of diet-induced obesity and causes hepatic insulin resistance, at least partly, via ER stress. In that experiment, autophagy was induced in the liver of mice with impaired proteasome function. In the present study, we investigated the relationship between proteasome function and autophagy in the development of insulin resistance in a cultured hepatocyte cell line.

Materials and methods: We isolated liver from mice fed a high-fat diet for 28 weeks. Proteasome activity was measured by the chymotrypsin-like protease activity. Rat hepatoma-derived H4IIEC3 cells were incubated with bortezomib (BZ), a selective inhibitor of the 26S proteasome. Insulin signaling pathways were evaluated by western blotting.

Results: Insulin receptor (IR) protein, but not IRS-2 protein, was decreased by ~30% without changing IR mRNA levels in the livers of mice fed a high fat diet (p<0.05, n=4). Unexpectedly, in the liver of these mice, proteasome activity was rather inhibited by 30% (p<0.05, n=4). Based on these *in vivo* findings, we addressed whether and how proteasome dysfunction is sufficient to cause insulin resistance *in vitro* by using H4IIEC3 hepatocytes. A proteasome inhibitor BZ concentration-dependently (10 to 100 μmol/l) increased proteins involved in an unfolded protein response, such as BiP and CHOP, and phosphorylation of IRE1α and c-Jun NH2-terminal kinase (JNK). IR protein and insulin-stimulated serine phosphorylation of Akt were markedly reduced by 20 and 40%, whereas IRS-2 protein levels were rather increased by 20 % in 100 μmol/l BZ-treated H4IIEC3 hepatocytes. Because BZ decreased IR protein, we evaluated the non-proteasomal pathways of protein degradation. BZ elicited accumulation of LC3B-II, a lipidated form of LC3B localized on the autophagic vacuoles (AVs), in H4IIEC3 hepatocytes. Most convincingly, electron microscopic examination of BZ-treated cells indicated a considerable increase of AVs.

Conclusion: Autophagy is likely activated in response to ER stress caused by accumulated misfolded proteins during proteasome inhibition. Present data also suggest that degradation of IR is induced through the lysosomal pathway, whereas IRS-2 is degraded through the proteasomal pathway in hepatocytes. Collectively, we propose a previously unrecognized role of ubiquitin-proteasome and autophagy-lysosome system for the development of insulin resistance in the liver.

Toll-like receptor-4 mediates obesity-induced nonalcoholic steatohepatitis through activation of x-box binding protein-1 in miceK.S.L. Lam^{1,2}, D. Ye¹, F.Y.L. Li¹, Y. Wang^{2,3}, K. Man⁴, C.M. Lo⁴, A. Xu^{1,2};¹Department of Medicine, ²Research Centre of Heart, Brain, Hormone and Healthy Aging, ³Department of Pharmacology & Pharmacy, ⁴Department of Surgery, The University of Hong Kong, China.

Background and aims: Nonalcoholic fatty liver disease (NAFLD) is an obesity-related chronic liver disorder ranging from simple steatosis to non-alcoholic steatohepatitis (NASH), which may progress to liver fibrosis and cirrhosis. This study aims to investigate the role of Toll-like receptor (TLR) 4 in mediating the transition from steatosis to inflammation.

Materials and methods: We generated ApoE^{-/-}/TLR4^{-/-} mice and ApoE^{-/-}/TLR4 wild type mice (ApoE^{-/-}/TLR4-WT) by cross-breeding the ApoE deficient (ApoE^{-/-}) strain with TLR4-deficient mice, which was then fed a high fat high cholesterol (HFHC) diet for 12 weeks to induce obesity.

Results: ApoE^{-/-}/TLR4-WT mice fed with high fat high cholesterol (HFHC) diet for 12 weeks developed typical pathological features of NASH in the context of obesity and metabolic syndrome. By contrast, ApoE^{-/-}/TLR4^{-/-} mice, which lack functional TLR4, were resistant to HFHC diet-induced liver inflammation and injury, and were less susceptible to the diet-induced production of reactive oxygen species (ROS) and proinflammatory cytokines. In ApoE^{-/-}/TLR4-WT mice, X-box binding protein-1 (XBP-1), a transcription factor involved in the unfolded protein responses, was activated in liver upon feeding with HFHC diet, whereas such an activation of XBP-1 was abrogated in ApoE^{-/-}/TLR4^{-/-} mice. In primary rat Kupffer cells, endotoxin induced XBP-1 activation through ROS production, whereas siRNA-mediated knockdown of XBP-1 expression resulted in a marked attenuation in endotoxin-evoked NF-κB activation and cytokine production. Furthermore, adenovirus-mediated expression of dominant negative XBP-1 in the liver led to a significant attenuation in HFHC diet-induced liver inflammation and injury in ApoE^{-/-} mice, but had little effect on hepatic lipid accumulation and ROS production.

Conclusion: These findings support the role of TLR4 in Kupffer cells as a key player in mediating the progression of simple steatosis to NASH, by inducing ROS-dependent activation of XBP-1.

Feeding a vitamin C and E enriched diet impairs the normal metabolic response to physical exercise in the liver of mice

M. Hoene, A.K. Pohl, H.-U. Häring, E.D. Schleicher, C. Weigert; Internal Medicine, University of Tuebingen, Germany.

Background and aims: The increased energy demand associated with prolonged physical exercise causes substantial changes in metabolite fluxes and

directly affects the liver, the key regulator of energy homeostasis. We could previously show that endurance exercise provokes a strong and acute response not only of metabolic, but also of stress-sensitive signalling pathways in the liver. Antioxidant intake with the aim of reducing oxidative stress has a high prevalence in the general population and among endurance athletes. However, excess intake of vitamin C and E could impair the adaptation of the muscle to physical exercise as well as beneficial effects on whole-body insulin sensitivity. We hypothesized that the response of the liver could be affected as well by antioxidant intake and attempted to clarify whether the underlying mechanisms are related to anti-oxidative or direct metabolic effects of these vitamins.

Materials and methods: Male C57BL/6 mice were supplemented during 4 weeks with control diet (n=12) or a vitamin C (100 mg/kg, control diet vitamin C-depleted) and vitamin E (2000 U/kg, control 149 U/kg) enriched diet (n=12) before 6 mice of each group were subjected to 1 h of treadmill running at non-exhaustive conditions (14 m/min, 14° uphill slope) while the others remained sedentary. Plasma and tissue metabolic parameters and mRNA levels in liver and skeletal muscle were assessed immediately after the bout of exercise.

Results: Plasma vitamin E concentration was two-fold increased after the diet (12.6 ± 0.6 vs. 6.5 ± 0.5 $\mu\text{mol/l}$, $p < 0.05$), and exercise-induced upregulation of the endogenous anti-oxidant metallothionein 1 (Mt1) in the liver was blunted in these mice. In contrast, the immediate early response of MAPK- and p53-dependent genes in the liver was not reduced by the vitamin C/E-diet. Most strikingly, the mice fed the vitamin C/E-diet did not show increased plasma free fatty acids after the run (784 ± 174 vs. 620 ± 139 $\mu\text{mol/l}$, $p < 0.05$). Well in line, induction of the PPAR α/δ target gene angiopoietin-like 4 (Angptl4) was prevented in liver and tibialis anterior muscle after exercise, as well as the hepatic increase in mRNA levels of the metabolic regulators PGC-1 α (Ppargc1a), pyruvate dehydrogenase kinase 4 (Pdk4) and insulin receptor substrate 2 (Irs2). The gluconeogenic enzyme G6Pase (G6p) was similarly induced in both groups, and liver glycogen content was not different after the run, while only mice fed the control diet had reduced plasma glucose levels afterwards (5.70 ± 0.50 vs. 7.24 ± 0.53 mmol/l in control, $p < 0.05$; and 7.09 ± 0.66 vs. 7.02 ± 0.29 mmol/l in vitamin C/E-fed mice). The trend towards lower triglyceride content in skeletal muscle after the run in vitamin C/E-fed mice further supports alterations predominantly in fatty acid metabolism.

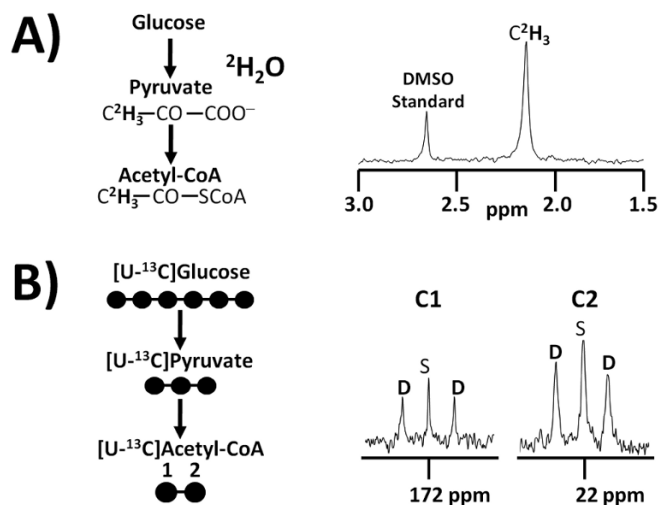

Conclusion: This study provides first evidence that the combination of vitamin C and E impairs the acute adaptive response to endurance exercise not only in the muscle, but also in the liver. The data suggest that this impairment could be due to metabolic rather than anti-oxidative effects. Possibly, vitamin E, which is closely linked to lipid turnover in the body, could directly interfere with fatty acid handling and thus affect the hepatic response to physical exercise.

N-acetyl PABA was purified by solid phase extraction and the acetyl carbon and hydrogen enrichments from $2\text{H}_2\text{O}$ and $[\text{U-}^{13}\text{C}]\text{glucose}$ were determined by NMR.

Results: Fig 1A and B shows representative 2H and ^{13}C spectra of N-acetyl-PABA recovered from protocols 1 and 2, respectively. From protocol 1, enrichment of the acetyl CoA methyl hydrogens from $2\text{H}_2\text{O}$ was estimated to be 2.2 ± 0.3 % compared to 2.4 ± 0.3 % for body water. This indicates that hepatic acetyl-CoA and body water enrichments were equivalent under these conditions. In Figure 1B, the ^{13}C acetyl signals of the N-acetyl PABA is shown. For each carbon, the ^{13}C - ^{13}C -coupled doublets (D), originating from the $[\text{U-}^{13}\text{C}]\text{glucose}$ precursor are well resolved from the background natural abundance ^{13}C singlet (S) allowing the excess acetyl-CoA ^{13}C -enrichment from $[\text{U-}^{13}\text{C}]\text{glucose}$ to be calculated. This was estimated to be $1.7 \pm 0.1\%$.

Conclusion: Analysis of murine hepatic acetyl CoA enrichment from $[\text{U-}^{13}\text{C}]\text{glucose}$ and $2\text{H}_2\text{O}$ by PABA administration and NMR analysis of N-acetyl-PABA was demonstrated. The analyses revealed that a surprisingly small fraction of hepatic acetyl-CoA ($< 2\%$) was derived from an intraperitoneal glucose load given to 24-hour fasted mice. This suggests that the liver was not committed to glycolytic and lipogenic utilization of the administered glucose under these conditions. Following $2\text{H}_2\text{O}$ administration, hepatic acetyl-CoA and body water hydrogens are enriched to the same levels hence body water enrichment can be used as a surrogate for the true acetyl-CoA precursor.

Noninvasive sampling of murine hepatic acetyl-CoA enrichment with p-amino benzoic acid

F. Carvalho¹, A. Gonçalves¹, J. Barra¹, M. Caldeira¹, J. Duarte^{2,3}, J. Jones^{3,4},

¹Chemistry, University of Coimbra, Portugal, ²Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, USA, ³Center for Neurosciences, Coimbra, Portugal, ⁴Associação Protectora dos Diabéticos de Portugal, Lisbon, Portugal.

Background and aims: Acetyl-CoA is a key hepatic metabolite but is difficult to analyze for enrichment from metabolic tracers. We developed a method that allows acetyl-CoA enrichment from ^{13}C - and 2H -enriched precursors to be quantified. p-Amino benzoic acid (PABA) is acetylated via hepatic acetyl-CoA and N-acetyl PABA is cleared into urine where it is analyzed. To demonstrate this sampling method, acetyl-CoA enrichment from deuterated water ($2\text{H}_2\text{O}$) was quantified by 2H NMR of N-acetyl-PABA in order to determine the true 2H -precursor enrichment for de novo lipogenesis. Second, the contribution of an $[\text{U-}^{13}\text{C}]\text{glucose}$ load to hepatic acetyl-CoA was determined by ^{13}C NMR analysis.

Materials and methods: In protocol 1, 4 mice were injected with $2\text{H}_2\text{O}$ in saline (3g/kg body water) one hour into the light phase, and their drinking water was also enriched with 3% $2\text{H}_2\text{O}$. 24 hours later, they received an injection of PABA (15 mg/kg) dissolved in saline containing 3% $2\text{H}_2\text{O}$. Urine was collected for 6 hours following PABA injection. In protocol 2, 4 mice were fasted overnight, then injected with $[\text{U-}^{13}\text{C}]\text{glucose}$ (2 g/kg) and PABA (15mg/kg) in saline. Urine was collected over the following 6 hours. Effects of acute exercise on hepatic lipid content

L. Bilet¹, B.M.W. Brouwers¹, E. van Ewijk^{1,2}, M.K.C. Hesselink³, V.B. Schrauwen-Hinderling^{1,2}, P. Schrauwen¹;

¹Human Biology, ²Radiology, ³Movement Sciences, MUMC, Maastricht, Netherlands.

Background and aims: There is increasing evidence that hepatic lipid content (IntraHepatic Lipid, IHL) markedly increases the risk of metabolic complications, including insulin resistance and cardiovascular events. Recent evidence suggests that exercise training might have beneficial effects on IHL content. However, it is unknown if an acute bout of exercise is able to lower IHL content. One confounding factor when investigating this research question is that acute exercise raises plasma fatty acid (FA) concentrations. We have previously shown that elevated concentrations of plasma FA, induced by exercise in the fasted state, lead to increased lipid accumulation in the heart and in non-active skeletal muscle. To circumvent this, we investigated the effect of acute exercise on IHL in both, the fasted and the glucose-fed state, as the increase in plasma FA concentrations is severely blunted in the latter condition. We hypothesized that acute exercise would be able to lower IHL content.

Materials and methods: Seven overweight male subjects (age: 57.4 ± 8.3 y, BMI: 28.4 ± 1.8 kg/m²) underwent hepatic Proton Magnetic Resonance Spectroscopy (¹H-MRS) (Intera, 1.5T, Philips Healthcare) in the morning in the fasted state to determine IHL content. Subsequently, subjects cycled for two hours at 50% of maximal performance. IHL content was measured directly after exercise and again four hours post-exercise. All subjects underwent this procedure twice, once while fasted, and once while ingesting glucose during both exercise and recovery from exercise (bolus: 1.4g/kg, 8 x 0.35 g/kg). Indirect calorimetry was used to determine whole body fat- and carbohydrate oxidation. Blood plasma samples were collected repeatedly for later analysis. For hepatic ¹H-MRS, an 18 cm³ VOI was placed within the lower right hepatic lobe (PRESS, TR = 4s, TE = 23ms, n = 64). Water signal was suppressed using frequency-selective prepulses. Spectra without water suppression were acquired with identical settings (n=64) and all spectra were fitted with AMARES in the jMRUI software. Values are given as T2-corrected ratios of CH₂ peak, relative to the unsuppressed water resonance (as percentage).

Results: RQ was significantly lower in the fasted condition compared with the glucose-supplemented condition during both exercise and recovery from exercise (0.77 ± 0.01 vs 0.85 ± 0.02 , respectively, $p=0.007$). Fat oxidation was significantly higher in the fasted condition compared with the glucose-supplemented condition (385.5 ± 108.3 mg/min vs 281.0 ± 87.5 mg/min, respectively, $p=0.004$). In the fasted condition IHL content was elevated directly after exercise and four hours post-exercise compared with baseline (from 1.72 ± 0.33 % at baseline to 1.91 ± 0.36 % post-exercise, $p=0.03$, to 2.06 ± 0.32 % four hours post-exercise, $p=0.023$), whereas it did not change when glucose supplementation was given (from 1.69 ± 0.32 % at baseline to 1.77 ± 0.36 % post-exercise, $p=0.30$, to 1.63 ± 0.35 % four hours post-exercise, $p=0.30$).

Conclusion: Acute exercise in the fasted state increased rather than decreased IHL content. However, IHL content did not change during exercise when the elevation of plasma FA in response to exercise in the fasted state was blunted by glucose intake. These data suggest that plasma FA concentrations play an important role in determining IHL content, and that a single bout of exercise may not be able to lower IHL.

Molecular basis of nonalcoholic fatty liver disease (NAFLD) in obese patients with or without glucose intolerance

M. Cardellini¹, P. Gentileschi², F. Davato², I. Cardolini², V. Marzano³, R. Menghini¹, V. Casagrande¹, I. Arisi⁴, D. Lauro¹, O. Porzio³, A. Urbani³, P. Sbraccia¹, R. Lauro¹, M. Federici¹;

¹Department of Internal Medicine, University of Rome Tor Vergata,

²Policlinico Tor Vergata, ³University of Rome Tor Vergata, ⁴European Brain Research Institute, Rome, Italy.

Background and aims: The basis of hepatocellular injury and progressive fibrosis in patients with obesity, Type 2 Diabetes and with nonalcoholic fatty

liver disease (NAFLD) is poorly understood. We sought to identify hepatic factors that are differentially abundant across the histologic spectrum of NAFLD.

Materials and methods: 45 non diabetic obese patients undergoing bariatric surgery (sleeve gastrectomy or gastric bypass) were characterized before the intervention with oral glucose tolerance, euglycemic hyperinsulinemic clamp, lipid and inflammatory biomarkers. Two biopsies were performed during the intervention, one for histological analysis and one for RNA and peptides extraction. RNA was extracted for differential gene expression with Affimetrix human GeneChips U 133 plus 2.0. Hepatic peptides were analyzed on an Q-TOF Premiere mass spectrometer with mass lynks/protein lynks software. 1-tail or 2-tail T tests were performed and used to screen for differential abundance gene expression or peptides expression, respectively.

Results: Patients were divided in four groups according to glucose tolerance status and NAFLD/NASH score: (1) obese with normal glucose tolerance/simple steatosis (NGT/SS, n=16), (2) obese with normal glucose tolerance/nonalcoholic steatohepatitis (NGT/NASH, n=7), (3) obese with type 2 diabetes/simple steatosis (DM2/SS, n=7), and (4) obese with type 2 diabetes/NASH (DM2/NASH, n=15). Comparative gene expression and protein abundance analyses were performed in a subset of DM2/NASH (n=3) and NGT/SS (n=3) patients. Most significant hits were controlled in the other samples by rtPCR and western blots. Gene expression analysis revealed that most significant annotation clusters were fatty acid biosynthesis, nucleosome core and response to hormone stimulus. Among most significant upregulated genes in DM2/NASH were: fatty acid binding protein 4, protein kinase AMP-activated alpha 2 catalytic subunit, neurotrophin Y receptor Y6 (pseudogene), CD36 molecule, serpin peptidase inhibitor, clade E (nexin, plasminogen activator inhibitor type 1) member 1. Most significant upregulated genes in NGT/SS were: complement component 1s subcomponent, interleukin 6 signal transducer (gp130), itchy E3 ubiquitin protein ligase homolog, salt-inducible kinase 1, pyruvate dehydrogenase kinase isozyme 4. Shotgun Proteomics revealed that 7 known proteins were significantly expressed with differential abundance between study groups. In DM2/NASH liver were highly expressed Cytochrome P450 2C19 GN (CYP2C19), Phosphoglycerate kinase 2 GN (PGK2) and Aldo-keto reductase family 1 member C4 GN (AKR1C4). We also found that Microsomal triglyceride transfer protein large subunit GN (MTTP), Glutathione S-transferase Mu 1 GN (GSTM1), Lumican GN (LUM) and Prelamin-A/C GN (LMNA) were highly represented in NGT/SS liver biopsies.

Conclusion: Our data suggest that the pathogenesis of liver inflammation and fibrosis in obese insulin resistant patients with histologically progressive NAFLD is associated to multiple pathways and particularly to a deregulation of lipid metabolism.

Interaction of lipid accumulation with mitochondrial function during the development of hepatic steatosis

G.F.B. Séquaris¹, J. Szendroedi¹, J. Kotzka², E. Phielix¹, B. Knebel², H.-J. Partke¹, D. Müller-Wieland³, M. Roden¹;

¹Institute for Clinical Diabetology, ²Institute for Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Düsseldorf, ³Department of Internal Medicine, Asklepios Clinic St. Georg, Hamburg, Germany.

Background and aims: In muscle, reduced ATP production relates to insulin resistance and fat storage. Recently, hepatic ATP production was also found to be lower in humans with type 2 diabetes and non-alcoholic fatty liver (NAFL). However, it is unclear whether hepatic energy metabolism may be impaired prior to the development of NAFL and thereby directly affects mitochondrial function. To address this question, we studied two transgenic mouse strains which develop NAFL due to liver- (alb-SREBP-1c: ALB) or adipose tissue- (ap2-SREBP-1c: AP2) specific overexpression of the lipogenic transcription factor, sterol regulatory-element binding protein-1c (SREBP-1c), and wild-type mice (CON) under unfasted (n: ALB=3, AP2=3, CON=7) and fasting conditions (n: ALB=4, AP2=5, CON=3). Alb-SREBP-1c mice develop primary NAFL due to stimulation of hepatic lipogenesis, while ap2-SREBP-1c mice exhibit lipodystrophy and excessively store liver fat resulting in secondary NAFL.

Materials and methods: Mitochondrial oxidative capacity (complex I and II) was measured by high-resolution respirometry (Oroboros Instruments) in permeabilized liver samples after addition of 2 mM malate, 10 mM pyruvate, 10 mM glutamate, 2.5 mM ADP and 10 mM succinate. Mitochondrial content was determined from the ratio of mtDNA to nuclear DNA, using quantitative

PCR. Serum insulin concentrations were determined fluorometrically by ELISA (Mercodia). Homeostasis model assessment-estimated insulin resistance (HOMA-IR) was computed from fasting glucose and insulin concentrations. **Results:** At 18 weeks, AP2 are lipodystrophic and have 37% greater ($p<0.001$) liver weight than in ALB and CON. Their livers showed doubled ($p<0.004$) state-3 mitochondrial oxidation rates of complex I and II compared to ALB and CON (AP2: 63 ± 7 , ALB: 31 ± 8 , CON: 31 ± 9 pmol.s⁻¹.mg⁻¹). On the other hand, hepatic mitochondrial content of AP2 was 17% lower than in ALB and CON (1.31 ± 0.03 , 1.57 ± 0.11 , 1.57 ± 0.08 ; $p<0.008$ vs. ALB and CON). In AP2, postprandial serum insulin concentrations were 3.2fold higher than in ALB and 6.8fold higher than in CON (AP2: 776.0 ± 89.4 , ALB: 243.8 ± 282.5 , CON: 113.4 ± 67.9 pmol/L; $p<0.001$ AP2 vs. CON; $p=0.003$ AP2 vs. ALB). HOMAR-IR indexes derived from fasting glucose and insulin levels revealed severe insulin resistance in AP2 (5.8 ± 2.0 , ALB: 2.2 ± 1.2 , CON: 1.0 ± 0.6 ; $p<0.02$ AP2 vs. ALB, $p<0.01$ AP2 vs. CON).

Conclusion: Adipose-tissue specific overexpression of SREBP-1c causes lipodystrophy with subsequent development of steatosis and insulin resistance. This is associated with lower content, but greater oxidative capacity of liver mitochondria and could result from elevated intrahepatic lipid supply and/or compensatory increased mitochondrial function.

Increased endogenous formation of N^ε-(Carboxymethyl)lysine in fatty liver induces inflammatory markers in an *in vitro* model of hepatic steatosis

K.H.J. Gaens¹, P.M.G. Niessen¹, S.S. Rensen², W.A. Buurman², J.W.M. Greve², A. Driessen³, J.G. Bloemen², C.H.C. Dejong², C.D.A. Stehouwer¹, C.G. Schalkwijk¹;

¹Internal Medicine, ²General Surgery, ³Pathology, Maastricht University, Netherlands.

Background and aims: (Nonalcoholic fatty liver disease) NAFLD is strongly associated with the presence and severity of obesity, and are associated with a high risk of developing insulin resistance and type 2 diabetes. Increased lipid peroxidation and cytokine-induced inflammation are major pathways in the pathogenesis of NAFLD. An important lipoxidation product that could play a role in the induction of hepatic inflammation is the biologically active advanced glycation/lipoxidation endproduct N^ε-(Carboxymethyl)lysine (CML). Therefore, the aim of the present study was to investigate the relationship between steatosis and the accumulation of CML, and to study the role of CML in hepatic inflammation.

Materials and methods: This study included 31 severely obese individuals, which were categorized into 3 groups according to the grade of hepatic steatosis. CML accumulation in liver biopsies was assessed by immunohistochemistry, and CML plasma levels were measured by ultra performance liquid chromatography-tandem mass spectrometry. CML plasma levels were also determined in a second cohort of 22 individuals with a range of body mass index (BMI). In these individuals, CML levels in the hepatic artery, portal vein and hepatic vein were determined and CML fluxes across the liver were calculated by multiplying arterialized-venous concentration differences with hepatic plasma flow. Hepatocyte HepG2 and HuH7 cell lines were used to study endogenous CML formation during intracellular lipid accumulation. Real time PCR analyses were performed to investigate the effects of CML on the expression of pro-inflammatory cytokines in cultured hepatocytes.

Results: CML accumulation in the liver was significantly higher in individuals with moderate and severe grade of steatosis compared with individuals with a low grade of steatosis (IHC score 2.0 ± 0.1 vs 1.2 ± 0.1 , $p<0.001$, and 1.9 ± 0.5 vs 1.2 ± 0.1 , $p=0.023$, respectively). Analysis of CML fluxes across the liver indicated that there was no release or uptake of CML by the liver. Intracellular lipid accumulation in cultured hepatocytes, as induced by incubation with a mixture of linoleic and oleic acids, was associated with increased endogenous CML formation in HepG2 and HuH7 cells (21% and 42% increase in CML levels, respectively, $p<0.05$ for both), which was accompanied by increased gene expression of receptor for advanced glycation endproducts (RAGE), plasminogen activator inhibitor-1 and interleukin-6. Endogenous CML formation and the increased gene expression were inhibited by pyridoxamine and aminoguanidine, both inhibitors of ALE formation.

Conclusion: There is a significant accumulation of CML in steatotic livers of obese individuals. The CML-induced inflammation in fatty livers may play a role in the pathogenesis of NAFLD and/or in the increased high risk of developing insulin resistance and type 2 diabetes.

Apolipoprotein C-I concentration is associated with liver fat content and triglyceride levels in patients with type 2 diabetes

B. Bouillet^{1,2}, T. Gautier², L. Lagrost², L. Duvillard^{3,2}, P. Buffier¹, B. Vergès^{1,2}, J.-M. Petit^{1,2};

¹Service d'Endocrinologie, Diabétologie, ²Unité INSERM CRI 866, ³Service de Biologie, Dijon, France.

Background and aims: Apolipoprotein (Apo) C-I mainly affects lipoprotein metabolism by inhibiting Lipoprotein Lipase (LPL) and promoting Very Low Density Lipoproteins (VLDL) production. In accordance with observations in mouse models, high Apo C-I levels have been shown to be associated with increased triglyceride (TG) concentrations and decreased visceral fat mass in men with metabolic syndrome. Non alcoholic fatty liver disease is commonly associated with obesity, metabolic syndrome and type 2 diabetes (DT2). So far, Apo C-I has never been studied in DT2. This prompted us to determine whether Apo C-I concentrations are associated with TG levels, visceral fat area and liver fat content in patients with DT2.

Materials and methods: Liver fat content (1H-magnetic resonance spectroscopy), area of visceral fat (single slice axial T1-RMN), Apo C-I and TG concentrations were measured in 121 patients with type 2 diabetes. High Apo C-I concentration was determined according to median Apo C-I concentration (77.4 mg/L).

Results: TG concentrations (2.85 ± 2.12 vs 1.85 ± 1.11 g/L, $p=0.001$) and liver fat content (13.51 ± 9.63 vs $9.73 \pm 8.3\%$, $p=0.02$) were significantly higher in patients with high Apo C-I compared with low Apo C-I. The visceral fat area was borderline significantly increased (266.71 ± 93.52 vs 242.71 ± 103.46 cm², $p=0.088$) in subjects with high Apo C-I levels compared with low Apo C-I. There was no correlation between Apo C-I concentrations and BMI and between ApoC-I levels and subcutaneous adipose tissue. In multivariate analyses, liver fat content (>median level:9.98%) was associated with Apo C-I (> median concentration:77.4 mg/L) ($p=0.01$), TG ($p=0.0287$) and BMI ($p=0.002$), but not with age and sex.

Conclusion: The association between high Apo C-I concentrations and decreased visceral fat described in patients with metabolic syndrome is not observed in type 2 diabetic patients. High Apo C-I levels are correlated with high TG levels and liver fat content in type 2 diabetic patients. Liver fat content is independently associated with Apo C-I. It may be explain by inhibition of LPL, which may increase TG concentrations and promote hepatic TG storage. Further studies are needed to evaluate cross-links between Apo C-I and fatty liver.

705

Regulation of hepatic lipid and cholesterol synthesis by PEPCK-C

J.A.G. Duarte^{1,2}, A.J. Potts¹, N.E. Sunny¹, S. Satapati¹, J.G. Jones², S.C. Burgess¹;

¹Advanced Imaging Research Center, UT Southwestern Medical Center, Dallas, USA, ²Department of Life Sciences and Center for Neurosciences and Cell Biology, University of Coimbra, Portugal.

Background and aims: Cytosolic Phosphoenolpyruvate carboxykinase (PEPCK-C) catalyzes the conversion of oxaloacetate to phosphoenolpyruvate. Although this step is classically considered gluconeogenic, PEPCK-C is also expressed in non-glucose producing tissues like adipose tissue and is more generally a cataplerotic pathway required to match mitochondrial anaplerosis to biosynthesis and dynamic regulation of the TCA cycle. In addition to gluconeogenesis (GNG), PEPCK-C is important for glyceroneogenesis (GyNG), triglyceride (re)esterification and mitochondrial function. Despite being required for GNG, we previously demonstrated that the control coefficient of PEPCK-C over hepatic GNG is surprisingly low (0.18), but that complete loss of liver PEPCK-C causes impaired mitochondrial function. Liver-specific PEPCK knockout mice have a remarkable increase in hepatic triglyceride levels after an overnight fast, further underscoring the importance of this enzyme in the regulation of lipid metabolism. GyNG is a pathway that shares most enzymatic reactions with GNG and is critical for triglyceride synthesis. The objective of this study was to determine the consequence of PEPCK-C loss of function on the regulation of GyNG and its broader impact on lipid metabolism.

Materials and methods: Three types of mice with graded expression of PEPCK-C were used in this study: control (pck-1 lox/lox), 70% (pck-1 lox/neo) and 90% (pck-1 lox + neo/del) whole body knockdown and a liver specific PEPCK Knockout (pck-1 lox/lox+AlbCre). Mice were I.P. injected

with 27 μ l/g 99.9% D₂O to achieve a body water enrichment of 4% and then given 4% deuterated drinking water and chow ad libitum for 4-days to label hepatic and adipose triglycerides and cholesterol. Tissue triglycerides were extracts via Folch extraction and purified via solid phase extraction before being analyzed by ¹H and ²H nuclear magnetic resonance (NMR). Synthesis of the glycerol and fatty acid moieties of triglycerides and cholesterol were determined from incorporation of deuterium compared to total deuterium body water enrichment.

Results: There was a direct correlation between synthesis fluxes and whole body PEPCK-C expression (see table). Remarkably, this correlation suggested a stronger control of fed state GyNG by PEPCK-C than we previously reported for fasted state GNG. Despite no obvious requirement for PEPCK-C in lipogenesis or cholesterologenesis, the synthesis of total FFA, unsaturated FFA and cholesterol strongly correlated with levels of PEPCK-C. This observation was most apparent in whole body PEPCK-C deficient mice and less evident in liver specific KO mice.

Conclusion: These data confirm an important role for PEPCK-C in glycerol and triglyceride metabolism and reveal an unexpected role for PEPCK-C in fatty acid and cholesterol synthesis

Obesity influences white matter integrity: a combined diffusion tensor imaging and voxel-based morphometric study

H.K. Karlsson¹, J. Tuulari¹, J. Hirvonen¹, V. Lepomäki¹, R. Parkkola², J. Hiltunen³, P. Salminen², P. Nuutila¹, L. Nummenmaa³;

¹Turku PET Center, ²University of Turku, ³Aalto University School of Science and Technology, Turku, Finland.

Background and aims: Obesity has profound impact on several organs, yet little is known about its effect on brain structure. In this study we wanted to test whether morbid obesity is associated with structural changes in the brain's white and gray matter integrity.

Materials and methods: We compared brains of 23 neurologically intact, morbidly obese subjects and 22 neurologically intact, age-matched normal-weight volunteers with diffusion tensor imaging (DTI) and voxel-based morphometry (VBM) of T1-weighted anatomical magnetic resonance imaging (MRI) images. Full-volume statistical parametric mapping (SPM) analysis was used to compare fractional anisotropy (FA) and mean diffusivity (MD) values as well as gray and white matter density between the obese and normal-weight groups.

Results: Obesity was associated with lowered FA and MD values as well as reductions in both focal and global gray and white matter volumes. The focal obesity-related structural changes were observed in brain regions governing reward seeking, inhibitory control and appetite. Regression analysis showed that focal FA and MD values as well as gray and white matter density in these regions were negatively associated with body fat percentage. However, correlations with blood pressure, triglycerides, LDL, HDL or HbA_{1c} were mostly nonsignificant.

Conclusion: Anatomical changes in the gray and white matter in the obese persons' brains may partly be due hormonal and metabolic factors. These focal reductions were observed in brain regions involved in reward processing and appetite control, thus they may further promote abnormal reward seeking and eating behavior in obese individuals. Our results suggest that in order to prevent overeating in obese individuals, both behavioral and pharmacological treatments for obesity should aim at modifying the functional properties of the reward and cognitive control circuitry.

Cerebral glucose metabolism in human type 1 diabetes is increased after treatment with insulin detemir compared to NPH insulin: possible explanation for differences in weight?

L.W. van Golen¹, M.C. Huisman², R.G. Ijzerman¹, N.J. Hoetjes², L.A. Schwarte³, P. Schober³, R.P. Hoogma⁴, M.L. Drent¹, A.A. Lammertsma², M. Diamant¹;

¹Diabetes Center/ Department of Internal Medicine, VU University Medical Center, ²Nuclear Medicine & PET Research, VU University Medical Center, ³Anesthesiology, VU University Medical Center, Amsterdam, ⁴Groene Hart Hospital, Gouda, Netherlands.

Background and aims: The aim of this study was to test the hypothesis that insulin detemir, which consistently has been shown to result in less weight gain than other insulin therapies, leads to a more pronounced effect on brain glucose metabolism than NPH insulin in human type 1 diabetes.

Materials and methods: Eighteen male type 1 diabetic patients (mean \pm SD; age 38.5 \pm 8.9 years, body weight 83.1 \pm 13.5 kg, BMI 24.7 \pm 2.6 kg·m⁻², diabetes duration 14.0 \pm 7.5 years, HbA_{1c} 7.5 \pm 0.7%) were included in a randomised cross-over study. Patients were treated with a basal bolus regimen for 2 periods of 12 weeks, starting with either insulin detemir or NPH insulin, in combination with insulin aspart. After each treatment period, all patients were scanned in the morning in the fasted state; patients had injected their last basal insulin the previous night. Dynamic [¹⁸F]-fluoro-2-deoxy-D-glucose (FDG) brain scans were acquired over 60 minutes using an HRRT (Siemens/CTI) PET scanner. Arterial blood was measured continuously using an on-line sampling system. Using a standard template, various brain regions

were defined automatically on an MRI scan. Cerebral metabolic rate of glucose uptake (CMRGlu) was obtained by non-linear regression of the regional time-activity curves using the standard irreversible 2-tissue compartment model with blood volume parameter together with an arterial plasma input function. A lumped constant of $0.83322 - 0.0043 \times (\text{arterial glucose level})$ was used, based on previous human and rat data. Differences between treatments were tested by paired 2-tailed t-tests.

Results: After 12 weeks, daily insulin doses and HbA1c were similar between treatment groups. Insulin detemir decreased body weight by 0.3 kg, whereas NPH insulin increased weight by 0.5 kg (between-group difference $p=0.18$). After treatment with insulin detemir, average brain CMRGlu was increased with 4.7% when compared to NPH insulin ($p<0.01$); this effect was consistently shown in all brain regions including those regions involved in appetite regulation. Arterial glucose levels during scanning were similar between treatments.

Conclusion: Treatment with insulin detemir versus NPH insulin resulted in an increase in cerebral glucose metabolism in men with type 1 diabetes, paralleled by a trend towards weight loss. These findings support the hypothesis that a differential effect on cerebral glucose metabolism may contribute to the consistently observed weight sparing effect of insulin detemir.

Does central dopaminergic activity influence metabolic parameters?

L. Brunerova¹, J. Potockova², J. Horacek³, M. Andel²;

¹Endocrinology, Mediscan Euromedic, ²Diabetologic Cetnre, II.

Department of Medicine, ³Psychiatric Centre Prague, Czech Republic.

Background and aims: Dopaminergic agonists have been proved to improve control of diabetes and lipids. Central dopaminergic activity can be measured by apomorphin challenge test (apomorphin increases growth hormone and decreases prolactin levels), which is a marker of dopaminergic activity. The aim of our study was to evaluate the relationship between central dopaminergic activity and metabolic parameters in healthy men.

Materials and methods: We examined 42 healthy men (average age 43.5 ± 7.4 years, BMI $27.4 \pm 5.7 \text{ kg/m}^2$), anthropometric (waist-hip ratio, blood pressure and body fat by bioimpedance) and metabolic (glycaemia, lipids, glycated hemoglobin) parameters were measured and HOMA index of insulin resistance was calculated at the beginning of the study. Sublingual apomorphine (0.033 mg/kg with 4 mg as the highest dose) was administered and basal prolactin and growth hormone were measured in -30, -15, 0, 15, 30, 45, 60, 75, 90, 120, 150, 180 minutes. Area under the curve for prolactin (AUCPRL) and growth hormone (AUCGH) was calculated using trapezoidal rule. Euglycemic hyperinsulinemic clamp (insulin 1 mg/kg/min) was performed and glucose disposal (M) calculated. Linear regression was used for statistical analysis.

Results: Negative correlation was observed between AUCPRL resp. AUCGH and total cholesterol ($r=-0.52$, $P=0.001$; resp. $r=-0.34$, $P=0.04$), triglycerides ($r=-0.42$, $P=0.009$; resp. $r=-0.36$, $P=0.03$), HOMA index ($r=-0.33$, $P=0.043$; resp. $r=-0.5$, $P=0.001$), percentage of body fat ($r=-0.44$, $P=0.009$; resp. $r=-0.45$, $P=0.007$) and BMI ($r=-0.36$, $P=0.013$; resp. $r=-0.56$, $P=0.0001$). Negative correlation was also found between AUCGH and glycated hemoglobin ($r=-0.55$, $P=0.0001$), AUCGH and diastolic blood pressure ($r=-0.35$; $P=0.039$), waist hip ratio ($r=-0.46$; $P=0.006$) and age ($r=-0.53$; $P=0.001$), whereas positive correlation between AUCGH and M ($r=0.36$, $P=0.039$). After adjustment for age and BMI negative correlation between AUCGH and HbA1c ($r=-0.37$, $P=0.016$), AUCGH and HOMA index ($r=-0.34$, $P=0.025$), resp. AUCPRL and total cholesterol ($r=-0.41$, $P=0.007$) remained statistically significant.

Conclusion: Lower central dopaminergic activity is connected with higher total cholesterol, glycated hemoglobin and HOMA index after adjustment for BMI and age in healthy men.

Impact of milk fat- and canola oil-enriched diets on peripheral glucose metabolism and insulin action in the mouse brain

T. Sartorius¹, A. Janessa¹, C. Rotermund¹, A. Peter¹, J. Machann², F. Schick², H.-U. Häring¹, A.M. Hennige¹;

¹Internal Medicine IV, ²Diagnostic and Interventional Radiology, University of Tuebingen, Germany.

Background and aims: Increased consumption of dietary fats and reduced physical activity are the most important environmental factors leading to obesity, insulin resistance and finally type 2 diabetes. In this respect, the source and structure of dietary fat plays an important role, and in vitro studies suggested that saturated fatty acids (SFA) impair insulin action and secretion while mono-unsaturated fatty acids (MUFA) might be beneficial. Along with alterations in insulin action and secretion in the periphery, the brain emerged as a target for SFA to impair insulin action and neuronal activity. Moreover, insulin resistance in the brain was linked to an increase in food intake, peripheral insulin resistance and physical inactivity. The aim of the study was to analyze the effect of dietary SFA versus MUFA in vivo in mice.

Materials and methods: Four-week old C57BL/6 mice were weaned on an isocaloric milk fat- or canola oil-enriched diet with a total fat content of 8.3% and on chow diet for 8 weeks and the impact on glucose tolerance, insulin sensitivity and secretion, as well as cortical (ECOG) and locomotor activity, assessed by radiotelemetric measurements, was evaluated. Magnetic resonance imaging (MRI) of total and visceral fat tissue was performed on a 3 T whole-body imager.

Results: Both groups of mice with fat-enriched diet displayed a significant increase in body weight compared to the control group which was accompanied by impaired locomotor activity. MRI measurements revealed a significant increase in visceral adipose tissue mass (vs. control: milk: $+134.3\%$, $p<0.001$; canola: $+85.3\%$, $p<0.05$). The increase in body fat was accompanied by an impairment in glucose tolerance and insulin secretion and increased plasma non-esterified fatty acid concentrations (milk: 740 ± 48 vs. control: $588 \pm 46 \text{ } \mu\text{mol/l}$, $p<0.05$) in the milk fat-enriched diet group but not in the canola fat group. Interestingly, radiotelemetry analysis revealed a significant decrease in cortical activity in the milk fat group while canola oil even improved cortical activity. In addition, an intracerebroventricular application of human insulin was accompanied by an increase in locomotor activity in canola oil- and chow-fed mice, while mice fed the milk fat-enriched diet displayed insulin resistance. In order to study molecular mechanisms of altered cortical activity by the two fat-enrichments, tyrosine phosphorylation of the insulin receptor (IR) was assessed in the brain after intravenous injection of human insulin. Thereby, an increase in insulin-mediated tyrosine phosphorylation of the IR in total brain lysates was detected in the chow and canola-fed animals, but absent in milk-fat fed mice.

Conclusion: Feeding of mice with either canola oil that consists predominantly of MUFA or milk fat characterized by a large amount of SFA significantly increased body weight and body fat mass compared to chow. Moreover, both diets are accompanied by a significant decrease in physical activity. However, glucose tolerance and insulin secretion were solely impaired in the milk fat group but unaffected in the canola fat group and this was also true for measures for insulin resistance in the brain. Therefore, upon a moderate isocaloric intake of dietary fat, SFA display aversive effects on insulin secretion and the brain while MUFA were protective.

A mouse model of Alzheimer's disease develops insulin resistance

M. Jimenez-Palomares¹, J.J. Ramos-Rodriguez², M. Pacheco-Herrero², M. Garcia-Alloza², I. Cozar-Castellano¹;

¹Hospital Universitario Puerta del Mar, Cadiz, ²Universidad de Cadiz, Spain.

Background and aims: Type 2 diabetes mellitus (T2DM) and Alzheimer's disease (AD) share many common features such as common susceptibility genes, production of amyloid plaques and predisposition with age. The risk to develop AD is double in patients with T2DM. Furthermore, DM may induce micro and macrovascular complications on the brain, a risk factor for AD. In parallel it has been reported that AD's predisposition can be linked to T2DM development. Lepr^{-/-} (db/db) mice develop obesity, hyperinsulinemia and hyperglycemia, being considered a model of obesity, insulin resistance and type 2 diabetes. Lepr^{+/-} mice do not show any metabolic phenotype, so

they are used, together with *lepr*^{+/+}, as a control group when compared to the *lepr*^{-/-}. APPsw mice overexpress amyloid precursor protein (APP) which is processed into Aβ peptide, these mice have detectable levels of Aβ on their plasma and they are used as a model of AD.

Materials and methods: We were interested in whether circulating high levels of Aβ can have an effect on glucose metabolism. We characterized the metabolic phenotype of transgenic APPsw versus wild type (WT) mice, measuring weight, blood glucose, plasma insulin, glucose tolerance and insulin response to glucose challenge *in vivo*.

Results: First we characterized 5–7 weeks old mice (APPsw versus WT) and found they are both, normoglycemic and normoinsulinemic, showing normal glucose tolerance test. Then, we decided to include a genetic risk to develop diabetes, breeding *lepr*^{+/+} mice with APPsw, generating *lepr*^{+/+} mice having the APPsw transgene (*db*^{+/+}; Tg-APP) or not (*db*^{-/-}; WT). We then characterized the metabolic phenotype of these mice, finding unexpectedly that *db*^{+/+}; Tg-APP were normoglycemic but hyperinsulinemic in non-fasting conditions and glucose intolerant, showing a phenotype of insulin resistance. Their hyperinsulinism is not mediated by improved beta-cell function, as their insulin levels 15 minutes after glucose challenge are similar in *db*^{+/+}; Tg-APP and in *db*^{+/+}; WT mice.

Conclusion: Thorough investigation will be performed for a better understanding of the phenotype (insulin tolerance test, pyruvate tolerance test, beta-cell mass) as well as mechanistic studies to decipher if insulin resistance is due to circulating APP or if it is secondary to alterations in the central nervous system (CNS). This study will shed light into the mechanisms underlying AD's link to T2DM, and it will give clues to the hypothesis that the individuals bounded to suffer the first disease will be predisposed to suffer the second one and vice versa.

Insulin 2 is present in the adult mouse brain and its gene expression controls food intake

J.D. Johnson, A.E. Mehran, S.M. Clee;

Cellular and Physiological Sciences, Diabetes Research Group, University of British Columbia, Vancouver, Canada.

Background and aims: The murine insulin 1 and insulin 2 genes are widely considered to be functionally redundant, despite reports of distinct tissue distribution, differential regulation in the embryo and distinct promoter elements. While it is obvious that pancreatic β-cells are the only source of circulating insulin, reports throughout the years have pointed to extra-pancreatic insulin production and local action (e.g. thymus, brain). The brain is a known target for insulin's effects on satiety and energy homeostasis. The goal of the present study was to further test the hypothesis that insulin 2 is selectively expressed in the adult brain and determine the effect of graded insulin 2 gene expression on high-fat food intake and obesity. We hypothesize that adult brain insulin 2 normally suppresses fatty food intake and peripheral insulin sensitivity, and that reductions in brain insulin 2 can cause obesity.

Materials and methods: We employed Taqman RT-qPCR with insulin 1 or insulin 2 knockout mice as controls to examine the mRNA expression of insulin 2 in multiple parts of the brain. We tested the effect of control and 58% high-fat diets on multiple parameters, including obesity, glucose homeostasis and food intake in *ins1*^{-/-}; *ins2*^{+/-} mice with reduced insulin 2 and their *ins1*^{-/-}; *ins2*^{+/+} littermate controls. All groups in this study lacked the pancreas-specific insulin 1 gene.

Results: *Ins1*^{-/-}; *ins2*^{+/-} mice on a control diet had significantly lower insulin release when compared to *ins1*^{-/-}; *ins2*^{+/+} mice. This was associated with a significant reduction in body weight. -Cell mass and glucose homeostasis were similar in all groups. Mice with low insulin 2 gene dosage (*ins1*^{-/-}; *ins2*^{+/-}) were initially hypersensitive to insulin on normal chow, but eventually became paradoxically insulin resistant. *Ins1*^{-/-}; *ins2*^{+/-} mice showed increased body weight on a high fat diet relative to *ins1*^{-/-}; *ins2*^{+/+} controls. Food intake was selectively increased in high fat-fed *ins1*^{-/-}; *ins2*^{+/-} mice relative to *ins1*^{-/-}; *ins2*^{+/+} mice, suggesting a central mechanisms of weight gain, consistent with a satiety role for insulin 2. We also found brain insulin 2 gene expression was reduced by high fat feeding, a potential vicious cycle.

Conclusion: Together with our work on insulin 1, our data strongly suggest that the insulin 1 and insulin 2 have distinct functions in body weight regulation and energy homeostasis. Our data clearly show insulin 2 in the brain. Local brain insulin 2 may play an amplified satiety role in the absence of insulin 1. Indeed, the *ins1*^{-/-}; *ins2*^{+/-} mice resemble brain-specific insulin receptor knockout mice, showing exaggerated obesity with a high fat diet. The expres-

sion of two murine insulin genes presents a unique opportunity to genetically dissect the tissue-specific roles of insulin 1 (pancreas) from the actions of insulin 2 (pancreas + brain). Since all mammals, including humans, express insulin in tissues outside the pancreas, our studies have the potential to help us understand the tissue- and diet-dependent effects of insulin on obesity and energy homeostasis.

Serum brain-derived neurotrophic factor (BDNF) concentration is down-regulated by Intralipid/heparin infusion in young and healthy male subjects

M. Karczewska-Kupczewska, I. Kowalska, A. Nikolajuk, A. Adamska, M. Zielinska, N. Kaminska, M. Górska, M. Straczkowski;

Department of Endocrinology, Diabetology and Internal Medicine, Medical University of Białystok, Poland.

Background and aims: Insulin resistance and type 2 diabetes are associated with an increased risk of neurodegenerative diseases. Brain-derived neurotrophic factor (BDNF) regulates neuronal differentiation and synaptic plasticity and its decreased levels are supposed to play a role in the pathogenesis of Alzheimer disease and other disorders. The aim of the present study was to estimate the effects of hyperinsulinemia and plasma NEFA elevation on serum BDNF concentration in humans.

Materials and methods: We studied 18 healthy male subjects (mean age 25.61±3.01 years; mean BMI 26.62±4.76 kg x m⁻²). Serum BDNF concentration was measured in the baseline state and in the 120 and 360 minutes of euglycemic hyperinsulinemic clamp with or without Intralipid/heparin infusion.

Results: There was more than 3-fold increase in plasma NEFA from the initial values during Intralipid/heparin infusion (*p*<0.001). Insulin sensitivity was not different during the second hour of both clamps (*p*=0.47), however, it was reduced by approx. 40% after six hours of Intralipid/heparin infusion (*p*<0.001). Hyperinsulinemia had no effect on serum BDNF concentration (*p*=0.89). Raising NEFA had no effect on serum BDNF in 120 minute (*p*=0.99), however, it resulted in a significant decrease by 43% in serum BDNF value after 360 minutes (*p*=0.005). Additionally, BDNF 360 min value of Intralipid/heparin was markedly lower in comparison with BDNF 360 minute value of the clamp without raising NEFA (*p*=0.007). Serum BDNF in 360 minute of the clamp was related to a decrease in insulin sensitivity during Intralipid/heparin infusion (*r*=−0.50, *p*=0.035).

Conclusions: Our data show that raising NEFA decreases serum BDNF. This might indicate a potential link between NEFA-induced insulin resistance and neurodegenerative disorders.

Type 2 diabetes alters the stem cell content of the stromal vascular fraction of subcutaneous adipose tissue

R. Ferrer-Lorente, M.T. Bejar, L. Badimon;

Cardiovascular Research Center (CSIC-ICCC), Barcelona, Spain.

Background and aims: Cell therapy is a promising option for treating ischemic diseases and heart failure. Nevertheless, it has recently been shown that aging and cardiovascular risk factors, such as diabetes, affect endogenous progenitor cells thereby limiting their therapeutic potential. The impact of diabetes on the number and function of endothelial progenitor cells (EPCs) and bone marrow derived progenitor cells (BMSC) is already known. However, its impact on other stem cell populations remains unclear. Recently, different tissues have emerged as possible stem cell sources, and adipose tissue represents a particularly abundant, practical, and appealing source for autologous cell replacement. Therefore, the aim of this study was to investigate the effects of diabetes on stem cell content in the adipose stromal vascular fraction (SVF).

Materials and methods: Subcutaneous adipose tissue from Zucker Diabetic Fatty (ZDF) and lean normoglycemic control (ZDFc) rats was dissected and processed for SVF isolation. Total RNA from the SVF was isolated and gene expression was analyzed by a specific Rat Stem Cell PCR Array. Additionally, total RNA from subcutaneous adipose tissue was isolated and specific stem cell markers expression were measured by real-time PCR.

Results: ZDFc rats showed normal blood glucose levels (92 ± 1.99 mg/dl) whereas those of ZDF rats were significantly higher (392.75 ± 11.62 mg/dl, p -value <0.0001 vs. lean controls) clearly reflecting their diabetic status. Real-time PCR analysis of subcutaneous adipose tissue showed a reduction of expression of stem cell markers CD90 (42.01 ± 6.38 %), CD29 (76.81 ± 9.51 %) and CD105 (71.32 ± 7.85 %) in ZDF compared to controls. However, only CD90 and CD105 showed a significant difference (p -value 0.0003 and 0.0289, respectively). The PCR Array used analyses expression of genes related to stem cell identification and growth. Diabetes was associated with an overall down regulation of stem cell specific markers in SVF (a cut off fold change of 1.5 was applied). Interestingly, mesenchymal cell lineage markers (Acan, Alpi, Bglap, Col1a1, Col2a1 and Col9a1), genes involved in signalling pathways important for stem cell maintenance (Notch and Wnt pathway) and genes involved in maintaining pluripotency and self-renewal status (Fgf4, Gdf3, Sox2 and Tert) showed a reduced expression in the SVF from diabetic rats.

Conclusion: These findings suggest that type 2 diabetes affects the maintenance of the "stemcellness" characteristics of stem cells and their content in the SVF of subcutaneous adipose tissue. Impairment of diabetic-derived progenitor cells might limit the efficiency of direct autologous stem cell therapy with SVF. Further isolation from stroma and characterization of these stem cells is required to truly confirm their therapeutic potential.

Early transcriptional activation of adipose genes precedes the phenotypic remodelling of adipose tissue in pregnancy

V. Resi¹, L. Presley², J. Minium², P.M. Catalano², S. Hauguel-de Mouzon²;

¹Malattie Metaboliche e Diabetologia, University of Pisa, Italy, ²Reproductive Biology, Case Western Reserve University, Cleveland, USA.

Background and aims: Pregnancy is characterized by significant changes in basal maternal metabolic homeostasis with extensive adipose tissue (AT) remodeling. Early gestation is viewed as an anabolic state with increasing maternal adipose stores to meet the feto-placental and maternal energy demands at later time. The aim of this study was to characterize the mechanisms responsible for adipose tissue remodelling focusing on the molecular events occurred in adipose tissue during the early stage of pregnancy.

Materials and methods: 11 women with normal glucose tolerance were recruited pre-gravid and followed-up longitudinally in early (8-12 weeks) pregnancy. The metabolic profile, body composition and insulin sensitivity were obtained at pre-pregnancy (P) and again at early pregnancy (E). White adipose tissue biopsies were obtained by liposuction in the subcutaneous gluteal depot at time P and E. Modification of adipose tissue transcriptome

were assessed by microarray (U133A2 Affymetrix) and RT-PCR of candidate genes.

Results: BMI, fat mass, adipose cell volume and cellularity and insulin resistance index were all significantly increased at L ($p < 0.001$) and unchanged at E compared to P. Among the 22,278 genes surveyed, the adipose tissue transcriptome encompassed 7612 ± 524 genes. At time E 15% of the adipose transcriptome (1286 genes) was significantly modified (645 increased and 641 decreased) and 10 % at time L. Stringent filtering (p value < 0.001 and $FC > \pm 1.5$) and hierarchical cluster analysis identified 4 main functional categories overrepresented in early pregnancy: metabolism related genes, ECM, immune regulation and angiogenesis. In the lipid cluster increased in ACLY-ATP citrate lyase, Stearoyl-CoA desaturase, Fatty acid synthase indicated enhancement of lipogenesis. There were an increase in genes regulating angiogenesis (VEGFA, IGF2-, MMP-14, fibronectin) and recruitment of LPS-sensing pathways (lipopolysaccharide binding protein, CD14-, Toll-like receptor 4, NFKB).

Conclusion: Early pregnancy is characterized by a combination of molecular events which precede the phenotypic changes of adipose tissue and body composition. The activation of immune and angiogenic regulation are novel findings suggesting that early inflammation and vascular growth prepare for adipose tissue remodeling at later stages of pregnancy.

715

Pericardial adipose tissue and stem cells in diabetics

M.T. Bejar, R. Ferrer-Lorente, L. Badimon;

Cardiovascular Research Center (CSIC-ICCC), Barcelona, Spain.

Background and aims: Several studies have shown adipose tissue plays an important role in endocrine regulation and as a source of mesenchymal stem cells (MSC) which might be involved in endogenous repair of organ damage. It has been suggested that pericardial adipose tissue (PAT) might interact with the vessel wall and regulate coronary artery disease progression. We hypothesized that diabetes can affect PAT-MSCs and reduce or modify their endogenous repair potential. In this study we aimed to investigate differences in PAT of ZDF (diabetic) and ZDFc (normal) rats in terms of their stem cell characteristics.

Materials and methods: PAT from ZDF and ZDFc rats was surgically excised and the stromal vascular fraction (SVF) isolated. Total RNA from SVF was extracted and gene expression analyzed by a specific Rat Stem Cell Array. The statistical analysis was realized with RT² Profiler™ PCR Array Data Analysis (SABiosciences). Biochemical analysis was performed following standard procedures.

Results: ZDF showed higher glucose levels than ZDFc (392.75 ± 11.62 mg/dl vs. 92 ± 1.99 mg/dl, p -value < 0.0001) at time of analysis (14th weeks). SVF-ZDF showed a significant reduction of cell content compared to control (p -value 0.01). Diabetic and control groups showed significant differences in gene expression with a general down-regulation trend in the diabetic rats. The most specific pluripotency markers (Tert, Sox2, Gdf3, Fgf4) were down-regulated and likewise several genes included in Notch and Wnt pathways (with important roles in stem cell maintenance). A few genes, involved in cell proliferation, were up-regulated in diabetic SVF (Cdc42, Col1a1, Fgfr1).

Conclusion: These results suggest that the number and pluripotency of stem cells in PAT are reduced in diabetes. Furthermore, genes involved in proliferation are up-regulated in diabetic PAT. These findings suggest that the increased progression of coronary artery disease found in diabetics may be associated to a lower endogenous repair capacity in PAT for organ damage.

The effect on endoplasmic reticular stress in the liver and pancreas of prediabetes and diabetes stage OLETF rats after alcohol ingestion

S. Lee, J. Son, O. Hong, S. Kim, B. Cha, H. Son, S. Yoo;

Endocrinology and Metabolism, Catholic University, Seoul, Republic of Korea.

Background and aims: Diabetes mellitus is caused by beta cell loss or insulin resistance. Endoplasmic reticular stress (ER stress) mechanisms have been known to play a key role in developing diabetes. ER stress is caused by multiple factors, and alcohol is also one of them. The present study investigated the effect of alcohol on ER stress in the liver and pancreas of Otsuka Long Evans Tokushima Fatty (OLETF) rats.

Materials and methods: The OLETF rats aged 11–16 weeks were in the prediabetic stage. The prediabetic experimental group (15 OLETF rats) was treated with Liber DeCali regular ethanol-containing liquid diet. The prediabetic control group (15 OLETF rats) was treated with Liber DeCali regular control diet (35% fat, 47% carbohydrate, 18% protein). The each group was subjected to pair-fed methods with the same calories from 11 week to 16 week. In addition, the OLETF rats aged 17–22 weeks were in the diabetic stage. The OLETF rats in diabetic stage were given the same diet as prediabetic OLETF rats during 6 weeks. The diabetic experimental group and diabetic control group had 15 OLETF rats, respectively. An intraperitoneal - glucose tolerance test (IP-GTT) was conducted at the end of 16 weeks at the prediabetic stage and 22 weeks at the diabetic stage, respectively. Hematoxylin and eosin staining was performed to observe the morphological changes of liver and pancreatic tissues following alcohol treatment. To assess the degree of ER stress, western blot analysis was performed using ER stress markers.

Results: In the liver, alcohol treatment at the prediabetic stage did not induce the ER stress. The alcohol treatment in the diabetic stage showed an increase in p-PERK, phosphorylation-eukaryotic translation initiation factor 2 α (p-eIF2 α), activated transcription factor 6 (ATF6) and inositol requiring enzyme-1 α (IRE1 α) ($p < 0.05$). However, phosphorylation-c-Jun N-terminal kinase (p-JNK) associated with insulin resistance decreased in the liver at both prediabetic stage and diabetic stage. Meanwhile, in the pancreatic tissue of prediabetic stage, alcohol treatment increased significantly the expression of p-PERK, p-eIF2 α , ATF6, glucose regulated protein 78/binding immunoglobulin protein (Grp78/BiP) and p-JNK ($p < 0.05$). The morphology of the pancreatic islet was damaged. However, growth arrest and DNA damage-inducible gene C/EBP-homologous protein (GADD153/CHOP) in the alcohol group was not different from that of the control group. The morphology of the pancreatic islet was severely damaged at diabetic stage. The expression of p-PERK, p-eIF2 α , ATF6, CHOP, BiP, IRE1 α and p-JNK increased by excessive alcohol ($p < 0.05$).

Conclusion: The alcohol, regardless of the progression of the diabetes, affected the pancreas more than the liver. The compensation mechanism for alcohol-induced damage was operated in the liver but all the mechanisms of ER stress caused the pancreas to negative effects from alcohol. Therefore, the incidence of diabetes may be increased by alcohol consumption, regardless of the progression of diabetes.

Methylglyoxal causes structural and functional alterations in adipose tissue independently of obesity

P. Matafome^{1,2}, D. Santos Silva¹, J. Crisóstomo¹, T. Rodrigues¹, L. Rodrigues¹, C.M. Sena¹, P. Pereira², R.M. Seica¹

¹Institute of Physiology, ²Center of Ophthalmology, IBILI, Faculty of Medicine, University of Coimbra, Portugal.

Background and aims: Adipose tissue alterations including impaired adipocytokine expression, cell death, hypoxia and macrophage infiltration occur since early type 2 diabetes stages as it is the first organ to develop insulin resistance even on moderate BMI values. However, the contribution of hyperglycemia to these events during type 2 diabetes progression was never object of study. In this work we intended to evaluate the role of chronic hyperglycemia and specifically methylglyoxal (MG) on adipose tissue dysfunction.

Materials and methods: We studied normal Wistar (W) rats and a non-obese model of type 2 diabetes, Goto-Kakizaki (GK) rats with 6 and 14 months old, in order to understand chronic effects of hyperglycemia and ageing. We also studied a group of W rats with MG administration (WMG) in order to study MG-specific mechanisms. Several functional and morphological aspects were assessed, namely adipocytokines, fibrosis, glycation, hypoxia and inflammation.

Results: Hyperglycemia (fasting and 2 hours after i.p. glucose administration) is intrinsic to our diabetic animal model ($P < 0.001$) and resulted in structural adipose tissue alterations, namely fibrosis and accumulation of PAS positive components, exacerbated in aged animals. Although in a lesser extent, these alterations were also observed in aged W rats and in MG-treated group. Decreased adiponectin circulating levels ($P < 0.05$) were observed in aged diabetic and MG-treated rats. Diabetic rats, aged W and WMG showed decreased Bcl-2/Bax ratio ($P < 0.05$) and increased caspase 3 expression ($P < 0.05$). Diabetic rats, aged W and WMG also had impaired VEGF/Ang-2 ratio ($P < 0.05$). These alterations led to interstitial hypoxia quantified by pimonidazole staining ($P < 0.05$) and decreased tissue irrigation quantified by Evans Blue infiltration ($P < 0.05$). In aged diabetic rats hyperglycemia resulted in increased MCP-1 ($P < 0.05$) expression and macrophage (F4/80: $P < 0.05$) accu-

mulation in adipose tissue, localized in glycated fibrotic regions. These events were also observed in W rats treated with MG, but not in the other groups. **Conclusion:** Ageing causes several structural and functional modifications of adipose tissue also observable in early type 2 diabetes stages. However, chronic hyperglycemia-induced MG accumulation leads to macrophage recruitment for glycated fibrotic regions, common features of adipose tissue dysfunction models and obese or metabolic syndrome patients. Our results show that MG contributes to adipose tissue dysfunction during type 2 diabetes progression.

Folate and vitamin B12 imbalance induces endoplasmic reticulum stress in human adipocytes

C. McCarthy¹, A. Adaikalakoteswari¹, J. Moore², A.L. Harte¹, A. Brown³, P.G. McTernan¹, P. Saravanan¹, G. Tripathi¹

¹Division of Vascular and Metabolic Health, Coventry, ²Systems Biology Centre, Coventry, ³CVGI Bioscience, AstraZeneca, Cheshire, UK.

Background and aims: Prospective longitudinal studies in humans show that low maternal B12 and high folate levels independently predict higher metabolic risk & insulin resistance in the offspring and a higher risk of adiposity, gestational diabetes and Type 2 Diabetes Mellitus (T2DM) in the affected mother. Folic acid and vitamin B12 are essential nutrients required by humans due to their involvement in cell formation and maintenance and participation in several vital reactions. Intracellularly, folic acid and vitamin B12 provide continuous critical support in maintaining the genomic stability of human cells through the prevention of chromosomal breakage, hypomethylation of DNA and myelin destabilization. Therefore, the aim of this study was to examine the underlying molecular mechanisms in human adipocytes affected by changes in folate and B12 concentrations using microarrays. One of the pathways significantly affected was the unfolded protein response (UPR) or endoplasmic reticulum (ER) stress pathway, which has recently been shown to be vital for initiation and integration of inflammation and insulin action in adipocytes. Therefore the effect of B12 and folate on this pathway and related pathogenesis in human adipocytes was investigated.

Materials and methods: Human pre-adipocyte cell line (Chub-S7) were grown and fully differentiated in different concentrations of vitamin B12 and folate; (1) Normal: Normal B12 (0.5 μ M) + Normal folate (6 μ M); (2) Null: No B12 + No folate; (3) F30: No B12 + High folate (30 μ M) and (4) F60: No B12 + High folate (60 μ M). The cells were harvested for RNA, conditioned media and protein after day 9 (d9) and 14 (d14) post-differentiation. Total RNA was isolated from Chubs-S7 (d9 and d14 post differentiation) and reverse transcribed to cDNA for microarray and quantitative real-time PCR analysis. Protein was used for western blotting.

Results: Microarray analysis revealed that ER stress was significantly upregulated in cells cultured in high folate conditions compared to the cells cultured in normal media. The two main pathways activated under these conditions were PERK and ATF6. Western blotting showed downstream target of PERK induced phospho-eukaryotic translation initiation factor 2- α kinase (p-eIF2 α) ($p < 0.05$) was significantly upregulated under high folate conditions. Furthermore, qRT-PCR showed that the downstream targets and other protein chaperones expressions were also increased in high folate conditions such as HERPUD1 ($p < 0.02$), activating transcription factor 4 (ATF4), eIF2 α and protein disulfide isomerase (PDI). mRNA expression levels of asparagine synthetase (ASNS): Normal vs F60, d14 ($p < 0.02$); Null vs F60 ($p < 0.01$), ERO1 α : Normal vs F60, d14 ($p < 0.04$), ubiquitin protein ligase E3B (UBE3B): Normal vs Null, d9 ($p < 0.05$) and activating transcription factor 6 (ATF6): Normal vs F60, d9 ($p < 0.02$) were also significantly altered.

Conclusion: Our results highlight that an imbalance of folate and B12 induces the expression of key genes mediating ER stress, promoting inflammation and inducing insulin resistance. Taken together these data suggest that a B12/Folate imbalance leads to a higher risk of developing obesity and T2DM. As a consequence, this study highlights that even subtle changes in the micronutrients (folate and B12) may have profound effects on the gene networks that regulate key metabolic functions.

Early induction of 11 β -HSD1 expression in 3T3-L1 preadipocyte differentiation by cAMP increasing agents

C. Palmieri, E. Torrecilla, G. Fernández-Vázquez, F. Sánchez-Franco, D. Vicent;
Endocrinology, Hospital Carlos III, Madrid, Spain.

Background and aims: Adipose tissue production of active glucocorticoids from inactive metabolites is considered a pathogenic mechanism for metabolic syndrome and type 2 diabetes mellitus. Cortisone activation in tissues is mediated by 11 β Hydroxysteroid Dehydrogenase type 1 (11 β -HSD1) and Hexose 6 Phosphate Dehydrogenase (H6PDH) which co-operate in reducing cortisone to cortisol. 11 β -HSD1 protein is undetectable during the first stages of 3T3-L1 adipogenesis and is heavily upregulated in fully differentiated adipocytes. For this reason 11 β -HSD1 activity is considered part of the terminal differentiated adipocyte phenotype with no relationship to adipocyte differentiation regulation. Nevertheless adipose vascular stromal cells and 3T3-L1 preadipocytes, are able to differentiate in the presence of inactive corticoids, what requires 11 β -HSD1 activity during the first steps of differentiation. The aim of our work was to investigate, at the mRNA level, the gene expression regulation of the cellular system for glucocorticoid production during the first stages of adipose differentiation. In addition we explored individually the action of in vitro adipogenic inducers on 11 β -HSD1 mRNA level to identify in vivo candidates for the process.

Materials and methods: 3T3-L1 preadipocytes were differentiated by exposing confluent culture to a differentiation medium containing 10% Fetal Bovine Serum, glucocorticoid, insulin and 3-isobutyl 1-methylxanthine (IBMX) as an intracellular cAMP increasing agent. Total RNA was purified from the cells, cDNA was synthesized by a retrotranscriptase reaction and quantified by Real Time PCR.

Results: Quantification of 11 β -HSD1 mRNA by quantitative PCR during the first hours after differentiation induction shows a two fold increase at 8 hours and an exponential rising afterwards that reaches 2000 folds the level of expression in confluent 3T3-L1 preadipocytes before induction. This regulation seems to be specific for 11 β -HSD1 since H6PDH, which cooperates with 11 β -HSD1 in glucocorticoid reactivation, is not regulated during early differentiation. Separate incubation of confluent 3T3-L1 for 24h with the components of the differentiation cocktail clearly indicates that upregulation of 11 β depends on IBMX and suggests that glucocorticoids have an inhibitory effect. Time course experiments during 3T3-L1 differentiation indicate that early regulation of 11 β -HSD1 doesn't depend on upregulation of CCAAT/Enhancer-Binding Protein β or δ (CEBP- β , CEBP- δ) which are known regulators of 11 β -HSD1 promoter.

Conclusion: The ability of 11 β -HSD1 to respond to intracellular cAMP increase as an early differentiation event suggests that 11 β -HSD1 may be part of a preadipocyte stress response mechanism relevant for adipose tissue function.

Bariatric surgery increases regional glucose uptake in adiposity

T.T. Pham¹, J.C. Hannukainen¹, A. Karmi¹, R. Parkkola², P. Nuutila¹;

¹Department of Medicine, Turku PET Center, ²Department of Medicine, Turku University Hospital, Finland.

Introduction: Studies have shown that bariatric surgery improves insulin sensitivity and decreases adipose tissue masses. The aim of this study was to investigate the effect of bariatric surgery on adipose tissue regional glucose uptake (GU).

Methods: The study consisted of 23 morbidly obese subjects (BMI = 42.6 ± 3.5 kg/m²), 15 with diabetes or pre-diabetes and 8 non-diabetics and they were compared with 10 healthy volunteers (BMI = 23.7 ± 0.9 kg/m²). All the obese subjects were randomized for two bariatric surgery techniques, either gastric sleeve (n = 10) or gastric bypass (n = 13). Abdominal GU was measured using positron emission tomography and ¹⁸F- fluoro-deoxy-glucose at fasting state and during euglycemic hyperinsulinemic clamp before and six months after the surgery. Magnetic resonance imaging (MRI) was used for abdominal fat mass assessment and anatomical reference.

Results: Bariatric surgery decreased average body weight by 26.9 ± 8.3 kgs (p<0.01) after six months. Abdominal subcutaneous adipose tissue (SAT) mass decreased postoperatively 7.5 ± 3.9 kg (p = 0.002) and 6.6 ± 1.3 kg (p < 0.001) respectively; and abdominal visceral adipose tissue (VAT) mass by 1.2 ± 0.5 kg (p = 0.001) and 1.8 ± 1.1 kg (p < 0.001) respectively. Whole-body insulin mediated glucose uptake (M value) was significantly impaired both in diabetics (11.8 ± 5.2 μ mol/min/kg) and in non-diabetics (14.0 ± 7.0 μ mol/min/kg) compared to controls (40.3 ± 9.5 μ mol/min/kg), both p < 0.001, and increased by 119 % (p < 0.001) in diabetics and by 81 % in non-diabetics (p = 0.001) six month after bariatric surgery. At fasting state, VAT and SAT GU remained unchanged after the surgery and no group differences were observed pre- or postoperatively with healthy controls. Insulin stimulated VAT and SAT GU increased postoperatively in all patients (by 3.4 ± 1.4 μ mol/min/kg, p=0.015 and by 3.7 ± 0.9 μ mol/min/kg, p=0.001 respectively). However, no differences in metabolic effects were observed between diabetic and non-diabetic obese patients.

Conclusion: Weight loss through bariatric surgery improved insulin stimulated regional glucose uptake in both abdominal visceral and subcutaneous adipose tissue in which sleeve and gastric bypass techniques effect similarly in diabetic and non-diabetic obese.

Abdominal adipocyte size predicts liver fat independent of age, gender, BMI, body fat distribution and PNPLA3 genotype in nondiabetic subjects

E.M. Petäjä¹, K. Sevastianova², A.I. Hakkarainen³, H. Yki-Järvinen⁴;

¹University of Helsinki, ²Department of Medicine, Division of Diabetes,

³Department of Radiology, ⁴Department of Medicine, Division of Diabetes, Helsinki University Central Hospital, Finland.

Background and aims: Adipocyte hypertrophy has been suggested to be causally linked with ectopic lipid accumulation in the liver. Factors known to regulate liver fat in humans include body mass index (BMI), body fat distribution and genetic variation in the patatin-like phospholipase domain-containing 3 gene (PNPLA3; adiponutrin) at rs738409 (16 positive studies). It is unknown, however, whether adipocyte size predicts liver fat content independently of these factors and, if so, how much of the variation it explains.

Materials and methods: Liver fat (¹H-MRS), intra-abdominal (IA) and abdominal subcutaneous adipose tissue (SC) volume (MRI), abdominal adipocyte size (collagenase digestion, light microscope) and the PNPLA3 genotype were determined in 113 nondiabetic subjects (age 40 ± 14 years, BMI 30.0 ± 5.5 kg/m², male-to-female ratio 55/78). Multiple linear regression analysis was used to identify independent predictors of liver fat content.

Results: In multiple linear regression, age, gender, BMI, the IA/SC ratio and PNPLA3 genotype explained 43% of variation in liver fat content. Addition

of adipocyte size into the model increased the percent of explanation to 52%. Independent predictors included age ($p=0.011$), BMI ($p<0.001$), PNPLA3 genotype ($p<0.001$), the IA/SC ratio ($p<0.001$) and adipocyte size ($p<0.001$) (Table 1).

Conclusion: Adipocyte size is a highly significant independent predictor of liver fat. While age, gender, BMI and the IA/SC ratio explain 43% of the variation in liver fat, addition of adipocyte size increases it to 52%.

Expression of anti-lipolytic receptors in human adipose tissues

L. Chamas, M. Neville, F. Karpe;
OCDEM, University of Oxford, UK.

Background and aims: Anti-lipolytic signals in adipose tissue could be related to insulin sensitivity through the generation of systemic non-esterified fatty acids. Recently uncovered G-coupled proteins receptors GPR109A, GPR109B and GPR81 respond to ligands produced in intermediary metabolism and convey an anti-lipolytic signal in adipose tissue. The endogenous ligand for GPR109A is beta-OH butyrate whereas lactate is the endogenous ligand for GPR81. Little is known about the regulation of these receptors in human adipose tissue. We hypothesize that depot-specific expression of these receptors could help explain tissue anti-lipolytic effects.

Materials and methods: Due to the high degree of sequence similarity between GPR109A and GPR109B, the existing commercially available Taqman gene expression assays were tested for specificity on in-house developed specific templates for the two genes. Both gene assays were found to be non-specific. Following this, specific expression assays were developed and validated. Expression for all three genes in human adipose tissue was determined using paired abdominal and gluteal biopsy samples from 20 healthy male and 20 healthy female subjects. The mRNA expression assays were run on an ABI-7900HT system and normalized to PPIA and PGK1. To assess the relevance of possible feedback loops, the plasma concentrations of the endogenous ligands were measured in plasma.

Results: GPR81 abdominal subcutaneous adipose tissue expression correlated positively with GPR109A ($p=0.0001$, $r=0.56$) and GPR109B ($p=0.001$, $r=0.49$) expression in the same depot, whereas the expressions of GPR109A and GPR109B were unrelated to each other. GPR109A showed a 1.34 fold higher expression in gluteal tissue compared to abdominal tissue ($p=0.012$). GPR109B showed a 1.45 fold increase in expression in gluteal tissue compared with abdominal tissue ($p=0.006$). No depot difference was observed for GPR81. Gender differences were not detected amongst any of the genes. When looking for effects of obesity, abdominal expression of GPR81 was 1.17 fold lower in obese individuals ($p=0.013$, $n=20$) driven by an 1.26 fold reduction of expression in the male group ($p=0.041$, $n=10$). No obesity effects were seen for the other genes. No correlations were seen between measured levels of beta-OH butyrate and the expression of its receptor GPR109A. The gluteal expression of GPR81 was negatively correlated with lactate levels overall ($p=0.026$, $r=-0.33$, $n=40$) and more so in obese men ($p=0.006$, $r=-0.79$, $n=10$).

Conclusion: GPR109A and GPR109B showed adipose tissue depot specific expression differences. Higher expression of the anti-lipolytic GPR109A was seen in the gluteal tissue, known for its lower lipolysis rate. Obesity did not affect the expression of GPR109A and GPR109B but lowered the expression of GPR81. Furthermore, plasma lactate (the ligand to GPR81) was negatively associated to GPR81 gene expression which suggests a ligand-receptor auto-feedback.

Background and aims: Gene expression of the main lipogenic enzymes is paradoxically decreased in obesity, but the mechanisms behind these findings are poorly known. Breast Cancer 1 (BrCa1) has been described to interact with acetyl-CoA carboxylase (ACC) reducing the rate of fatty acid biosynthesis in lipogenic tissues.

Materials and methods: BrCa1 gene expression, total and phosphorylated (P-)BrCa1 and ACC were analyzed in adipose tissue samples obtained from a total sample of 133 subjects. BrCa1 gene expression was also analyzed during in vitro differentiation of human adipocytes and 3T3-L1 cells.

Results: BrCa1 gene expression was significantly up-regulated in both omental (OM; 1.36-fold, $p=0.002$) and subcutaneous (SC; 1.49-fold, $p=0.001$) adipose tissue from obese subjects. In parallel, P-ACC was increased in SC ($p=0.007$) as well as in OM fat ($p=0.010$). Consistent with its role of limiting fatty acid biosynthesis, BrCa1 mRNA was up-regulated in pre-adipocytes (both mRNA, 3.5-fold, $p<0.0001$, and protein, 1.2-fold, $p=0.001$) and decreased during adipogenesis in both human adipocytes and 3T3-L1 cells, while P-ACC decreased during differentiation of adipocytes ($p=0.005$) allowing lipid biosynthesis.

Conclusion: The specular findings of BrCa1 and lipogenic enzymes in adipose tissue and during differentiation of adipocytes suggest that BrCa1 might help to control fatty acid biosynthesis in adipocytes and adipose tissue from obese subjects.

Effects of dexamethasone on gene expression and glucose uptake in human subcutaneous and omental adipose tissue

J. Palming¹, M.J.R. Pereira¹, M.K. Svensson², M. Rizell³, J. Dalenbäck⁴, M. Hammar⁵, J.W. Eriksson⁵;

¹Lundberg Laboratory for Diabetes Research, Sahlgrenska Academy at University of Gothenburg, ²Molecular and Clinical Medicine, Sahlgrenska University Hospital, ³Department of Surgery, Sahlgrenska University Hospital, Gothenburg, ⁴Department of Surgery, Frölunda Specialist Hospital, Gothenburg, ⁵AstraZeneca R&D, Mölndal, Sweden.

Background and aims: Endogenous cortisol production is suggested to play a role in the development of the metabolic syndrome, visceral obesity and T2DM. We studied the effect of the synthetic glucocorticoid dexamethasone (Dex) on gene expression and glucose uptake capacity in human subcutaneous and omental adipose tissue aiming to identify new mechanisms and biomarkers for insulin resistance.

Materials and methods: Subcutaneous and omental adipose tissue were obtained from 17 patients going through elective abdominal surgery for non-malignant disorders (8 M/9 F; age 28-57 yrs; BMI 20.7-30.6 kg/m²). The adipose tissue was incubated in absence or presence of Dex (0.01-3 μM) for 24 h. After incubation, adipose tissue was saved for RNA extraction and adipocytes were isolated for glucose uptake analysis and cell size determination. DNA microarray analysis (Affimetrix, Human Exon 1.0 ST

Array) was performed in a pilot subgroup of 4 males and pathway analysis was performed.

Results: Dex changed the expression of 527 genes in both subcutaneous and omental adipose tissue at a maximally effective concentration (3 μ M). Pathway analysis of Dex-regulated genes showed a clear over-representation of functions and pathways related to inflammation. Single genes affecting lipolysis, glucose uptake and oxidation or adipocyte differentiation was changed after Dex incubation. Only two genes were differently regulated by Dex between the depots; CYP4Z1 (cytochrome P450, family 4, subfamily Z, polypeptide 1) expression increased in subcutaneous, but not in omental adipose tissue, and C13orf36 (chromosome 13 open reading frame 36) expression decreased in omental but not in subcutaneous adipose tissue. The expression of the secreted peptides leptin and TIMP4 (metallopeptidase inhibitor 4) were increased by Dex in both depots. Dex (3 μ M) exerted a greater inhibition of basal glucose uptake in omental vs subcutaneous adipocytes (by about 40%, $p < 0.01$ vs 30%, $p < 0.05$; $n = 10$). Dex (0.01–3 μ M) had a concentration dependent effect on basal and maximal insulin stimulated glucose uptake in both subcutaneous and omental adipocytes ($n = 4$). EC50 for the Dex effect to inhibit glucose uptake was about 2-fold lower in omental compared to subcutaneous adipocytes. Adipocyte size was not influenced by Dex in either of the adipose tissue depots.

Conclusion: Dex at maximally effective concentration similarly influences gene expression in both subcutaneous and omental adipose tissue depots. Adipocyte glucose uptake capacity is reduced by Dex, with omental adipocytes tending to be more sensitive than subcutaneous adipocytes. Leptin and TIMP4 are potential candidates to be used as circulating biomarkers for glucocorticoid-mediated insulin resistance. The gene expression changes are currently being evaluated with respect to magnitudes, dose-response relationships and links to glucose metabolism in the two fat depots.

Inverse regulation of lipolysis in different intra-abdominal fat depots in mice

S. Wueest¹, J. Liu², E.J. Schoenle¹, D. Konrad^{1,3}

¹Division of Pediatric Endocrinology/Diabetology and Research Centre for Children, University Children's Hospital Zurich, Switzerland, ²Department of Pediatrics, University of Kentucky, Lexington, USA, ³Zurich Centre for Integrative Human Physiology, University of Zurich, Switzerland.

Background and aims: Given the strong link between visceral adiposity and morbidity including hepatic steatohepatitis, it is crucial to characterize obesity-associated alterations in adipocyte function particularly in fat depots drained to the liver. Yet, such depots are not easily accessible in humans, and the most frequently-studied depot in rodent models is the perigonadal fat pad, which is drained systemically. Thus, here we aimed to study metabolic alterations in mesenteric compared to perigonadal adipocytes in mice.

Materials and methods: C57BL/6J mice were put on chow or high fat diet (HFD) for 8 weeks. Adipocytes from perigonadal and mesenteric fat depots were isolated by collagenase digestion. Viability and lipolysis (basal, isoproterenol- and insulin-stimulated) were measured and size of adipocytes was determined. Protein levels and mRNA expression were determined by Western blot technique and real-time RT-PCR, respectively.

Results: Relative increase in adipocyte size due to HFD was higher in perigonadal compared to mesenteric adipocytes (55.6 \pm 5.6% in perigonadal vs. 37.6 \pm 3.4% in mesenteric, $p < 0.05$). In chow-fed mice, the anti-lipolytic effect of insulin was higher in perigonadal compared to mesenteric adipocytes (42.4 \pm 4.6% in perigonadal vs. 10.2 \pm 3.5% in mesenteric, $p < 0.01$), while there was no difference under HFD (9.6 \pm 9.2% in perigonadal vs. 25.3 \pm 12.9% in mesenteric, $p = 0.2$). Basal NEFA release in perigonadal adipocytes was significantly higher in HFD- compared to chow-fed mice (4.5 \pm 0.5 mmol/10⁶cells*60min in chow-fed vs. 8.5 \pm 1.2 mmol/10⁶cells*60min in HFD-fed, $p < 0.01$) whereas there was no increased lipolysis in mesenteric adipocytes upon HFD (25.1 \pm 9.3 mmol/10⁶cells*60min in chow-fed vs. 13.3 \pm 2.0 mmol/10⁶cells*60min in HFD-fed, $p = 0.2$). Consistently, while high fat feeding led to an approx. 45% increase of NEFA levels in systemic circulation ($p = 0.05$), NEFA levels in portal blood were comparable between chow- and HFD-fed mice. In addition, protein levels of the G_o/G_i switch gene 2 (GOS2), which were previously found to be inversely related to basal lipolysis, decreased under HFD in perigonadal adipocytes but increased in mesenteric adipocytes. Similarly, perilipin levels (mRNA and protein) were differently regulated between the two depots.

Conclusion: Lipolysis is differently regulated between perigonadal and mesenteric adipocytes and these depot-specific differences might be explained by altered regulation of GOS2 and/or perilipin content.

Characterisation of the metabolic fluxes in the adipocyte differentiation process using bioinformatics tools

A. Miranda¹, S. Marín¹, V. Selivanov¹, S. Rodríguez-Cuenca², M. Cascante¹

¹Departament de Bioquímica i Biologia Molecular, Universitat de Barcelona, Spain, ²University of Cambridge Metabolic Research Laboratories, UK.

Background and aims: White adipose tissue mass is a critical factor determinant for obesity and associated health risks. The formation of new adipocytes from the differentiation of pre-adipocytes is accompanied with important metabolic changes. Stable isotope tracer data is used to reveal the metabolic flux profile in cells under studied conditions, and thus to provide an insight into the cell phenotype. The *de novo* adipocyte differentiation and the associated changes of metabolic flux profile were studied on the 3T3-L1 cell line incubated with stable isotope tracers. The use of a software simulating the measured data ensures the acquisition of more information and the elaboration of a metabolic map, taking into account all the available information throughout the differentiation process.

Materials and methods: 3T3-L1 preadipocytes were cultured with 25 mM glucose DMEM medium with 10% NCS and differentiated with DMEM containing 10% FBS, 0.5 mM 3-isobutyl-1-methylxanthine, 1 μ M dexamethasone and 1 μ M insulin (designated day 0). At day 3 the medium was replaced by DMEM containing 10% FBS and insulin, and at day 6 the medium was changed to DMEM with 10% FBS, and was changed every two days. Biochemical determinations of glucose, lactate, glutamate and glutamine were performed from day 0 to day 9. Incubations with 25 mM glucose 50% enriched with [1,2-¹³C₂]-D-glucose were performed for 24 hours at day 0 (preadipocytes), day 4 (immature adipocytes) and day 8 (mature adipocytes). The biochemical concentrations and isotopologic patterns of glucose, lactate, glutamate, glycogen, ribose and fatty acids were measured at the beginning and at the end of the incubations, the rates of production and consumption were calculated, and Mass Isotopomer Distribution Analysis and flux estimation with our software Isodyn was performed.

Results: The biochemical measurements indicated three distinct periods. Day 0 to day 4 was characterized by a glucose-to-lactate ratio of 1:2 and positive glutamine consumption. Days 4 to 7 the glucose consumption increased, although the glucose-to-lactate ratio approached 1:1, and from day 7 the consumption of glucose decreased, and glutamine production was observed. Using the isotopologue data obtained in our experiments and our custom metabolic software Isodyn we quantified the metabolic flux distribution in the glucose metabolic network.

Conclusion: The analysis of the isotopic distribution allowed us to evaluate the dynamics of metabolic fluxes in the central carbon metabolism. The results are consistent with previous works in the field. Dramatic changes in glycogen accumulation were observed throughout the differentiation process, and a metabolic rearrange in anaplerotic pathways was observed. The analysis with Isodyn allows us to define the whole set of metabolic fluxes inside the cell, defining the changes in the metabolic phenotype during the differentiation process.

Low B₁₂ and high folate: a novel regulator of cholesterol biosynthesis in human adipocytes

A. Adaikalakoteswari¹, J. Moore², P.G. McTernan¹, S. Kumar¹, P. Saravanan¹, G. Tripathi¹

¹Diabetes and Metabolism Unit, Clinical Sciences Research Institute, Coventry, ²Warwick systems biology centre, School of life sciences, Coventry, UK.

Background and aims: Vitamin B12 and folate play a crucial role in genomic stability of human cells and several other critical pathways during development and adult life. Peri-conceptional nutrition is associated with increased metabolic risk in the offspring. Prospective, longitudinal studies in humans show low maternal vitamin B12 and high folate levels independently predict: higher metabolic risk & insulin resistance in the offspring, higher risk of adi-

posity, gestational diabetes and type 2 diabetes in the affected mother. This is supported by an animal study, which showed that B12 and folate mediate a vital role in determining offspring's metabolic risk by DNA methylation. "Low B12 and high folate" imbalance is increasingly common, may partly be due to folic acid fortification programmes. It is intriguing that such "imbalance" causes hyperhomocysteinaemia, higher incidence of anaemia & cognitive dysfunction in elderly and higher metabolic risk of offspring when present in mothers. Therefore, to elucidate the underlying molecular mechanisms, gene expression analysis was done to study the effect of B12 and folate on human pre-adipocyte cell line using microarray analysis.

Materials and methods: Human pre-adipocyte cell line Chub-S7 was grown and fully differentiated in different concentrations of vitamin B12 and folate such as (1) Normal: Normal B12 (0.5µM) + Normal folate (6µM); (2) Null: No B12 + No folate; (3) F30: No B12 + High folate (30µM) (4) F60: No B12 + High folate (60µM) for 14–21 days. Total RNA was then isolated for microarray and reverse transcribed for quantitative real-time PCR analysis.

Results: Microarray analysis revealed that 491 genes were differentially expressed significantly ($p < 0.05$) in adipocytes treated with different concentrations of B12 and folate compared to normal B12/folate levels. Our results screened that genes involved in different biological processes and metabolic pathways were modulated including the cholesterol synthesis pathway. Differential array expression analysis examined that genes involved in biosynthesis of cholesterol occurring in three important phases: (1) mevalonate formation from acetyl-CoA by 3-hydroxy-3-methyl glutaryl-CoA synthetase (HMGCS1) & 3-hydroxy-3-methyl glutaryl-CoA reductase (HMGCR) (2) conversion of mevalonate to squalene by isopentenyl diphosphate isomerase (IDI1) and (3) squalene conversion to cholesterol by sterol C4 methyl-oxidase-like (SC4MOL) & squalene epoxidase (SQLE) were significantly modulated ($p < 0.001$ to $p < 0.05$). In addition, genes regulating cholesterol levels such as insulin induced gene-1 (INSIG1) ($p < 0.01$) and StAR-related lipid transfer domain4 (STARD4) were significantly up-regulated ($p < 0.05$). Validation by real-time PCR confirmed that these genes ($p < 0.01$ to $p < 0.05$) were up-regulated by different concentrations of B12 and folate compared to normal B12/folate levels.

Conclusion: Our data provides novel evidence that imbalance of B12/folate alters gene expression in cholesterol biosynthesis and regulation, thus potentially predisposing to obesity-associated dyslipidemia and insulin-resistance syndromes. This is the first report, unravelling the powerful effect of these micronutrients on gene networks that regulate many important metabolic functions in human adipocytes.

Autophagy activity is up regulated in adipose tissue of obese individuals and controls pro-inflammatory cytokine expression

P. van Essen, R. Stienstra, T.B. Koenen, H.J. Jansen, L.A.B. Joosten, M.G. Netea, C.J. Tack;
Radboud University Nijmegen Medical Center, Netherlands.

Background and aims: Autophagy is a cellular mechanism which rearranges the cellular structure and provides essential nutrients by degrading intracellular organelles or protein aggregates. Essential autophagy-related proteins are LC3 and ATG7. Recent studies have shown that autophagy also governs pro-inflammatory cytokine production in peripheral blood mononuclear cells. The development of obesity is often accompanied by a chronic low grade inflammation in adipose tissue. Together, these results suggest that autophagy may regulate inflammation in adipose tissue. We hypothesized that altering autophagy activity will affect pro-inflammatory cytokine expression in adipocytes.

Materials and methods: Human and mouse adipose tissue and human SGBS adipocytes were treated with the autophagy inhibitor 3-methyladenine (10 mM) (3MA) or siRNA to block ATG7. Expression and production of cytokines was evaluated by Real-time PCR, ELISA and western blotting techniques.

Results: Our results show that autophagic activity is increased in adipose tissue of obese animals (1.44 ± 0.12 LC3:actin ratio in wt mice vs. 12.32 ± 1.188 in obese mice; $p < 0.001$). Similarly, levels of the autophagy marker LC3 were elevated in subcutaneous adipose tissue of obese vs. lean individuals (0.24 ± 0.031 LC3:actin ratio in lean vs. 0.51 ± 0.13 in obese individuals; $p < 0.05$). Treatment of human subcutaneous adipose tissue explants with 3MA to reduce autophagy led to a significant increase in IL-1 β , IL-6 and IL-8 gene expression (relative fold change of 1,00 vs. 6.75 ± 0.68 for IL-1 β , 1,00 vs. 22.53 ± 17.10 for IL-6 and 1,00 vs. 6.90 ± 1.50 for IL-8; $p < 0.05$). In addition, secretion levels of the pro-inflammatory cytokines by subcutaneous adipose tissue explants were similarly enhanced after treatment with 3MA (1318 ± 244.0 vs. 3782 ± 618.2 pg/ml/g IL-1 β , 326.9 ± 78.93 vs. 643.6 ± 84.25 ng/ml/g IL-6 and 514.6 ± 167.4 vs. 1480.0 ± 160.4 ng/ml/g IL-8; $p < 0.05$). Treatment of visceral adipose tissue explants and SGBS adipocytes with 3MA showed comparable results. Alternatively, blocking of the autophagy protein ATG7 activity in vitro using small interfering RNA (siRNA) treatment led to similar results since it promoted inflammatory gene expression in SGBS cells (relative fold change of 1,00 vs. 3.93 ± 0.30 for IL-1 β , 1,00 vs. 3.79 ± 0.36 for IL-6 and 1,00 vs. 15.90 ± 2.52 for IL-8; $p < 0.05$).

Conclusion: Our results demonstrate that autophagy activity is up regulated in adipose tissue of obese individuals and controls pro-inflammatory gene expression. Autophagy may function to regulate inflammatory gene expression and prevent chronic inflammation in adipose tissue.

Transcriptomic analysis of macrophage polarisation: role of PPAR γ in alternative activation

E. Derlindati, I. Zavaroni, D. Ardigo;
Internal Medicine, University of Parma, Italy.

Background and aims: Human macrophages (HM) undergo different forms of activation in response to cytokines. Classical activation (M1) displays pro-inflammatory properties, and can be induced by IFN γ and/or LPS. Alternative activation (M2a) shows immuno-regulatory properties and is promoted by IL-4, whereas IL-10 produces a "deactivated" state, with immunosuppressing characteristics (M2c). Glitazones are the newest class of oral type-II antidiabetic agent and are a selective agonist for peroxisome proliferator activated receptor gamma (PPAR- γ). The PPAR γ system appears to be implicated in M2a activation enhancing their anti-inflammatory properties. The aim of the study is the evaluation of the biological processes involved in the different types of HM activation compared to the effects induced by exposure to PPAR γ -agonists.

Materials and methods: HM were stimulated with INF γ +LPS (M1), IL-4 (M2a), IL-10 (M2c), or a PPAR γ -agonist (GW1929-Sigma). Phenotypic changes for each experimental condition were investigated through whole-genome transcriptomic analysis by microarrays (Agilent-Technologies).

Gene ontology (GO) analysis was performed using Gorilla tool. Validation was obtained by RT-PCR on the most differentially expressed genes.

Results: After characterization of M1, M2a, and M2c genomic profiles, we investigated the differences between PPAR γ -stimulated HM and M1, observing a significant decrease in immunitary and inflammatory processes (corresponding GO-term's p -value=2.00*10⁻³⁵ and 1.20*10⁻²⁰) and a great increase in cell cycle activity (p =1.51*10⁻³⁵). Similar, but quantitatively lower, results were observed also in comparison with M2a and M2c, although these two subpopulations are usually regarded as anti-inflammatory.

Conclusion: Exposure of HM to a PPAR γ -agonist induces a transcriptomic phenotype closer to M2a/M2c than to M1. Nevertheless, PPAR γ -agonist activation decreases inflammatory cytokine production and increases cell-cycle gene expression also compared to cytokine-induced M2a and M2c activation, suggesting a specific role of PPAR γ in the regulation of macrophage differentiation. These results can partially explain the anti-inflammatory properties of glitazones, actually widely employed in clinical practice.

Physical exercise improves infiltration and polarisation of macrophage in white adipose tissue of diet-induced obesity rats

A.G. Oliveira, B.M. Carvalho, G.Z. Rocha, T.G. Araujo, D. Guadagnini, J.B.C. Carvalho, M.J.A. Saad;
Internal Medicine, State University of Campinas, Brazil.

Background and aims: Increased infiltration of white adipose tissue (WAT) by macrophages plays an important role in the establishment of the chronic inflammatory state and metabolic dysfunction (e.g., insulin resistance) that is associated with obesity. In obese animals, macrophages assume a proinflammatory classical activation profile also known as M1, in contrast to lean conditions with an alternative activation state (M2) and production of immunosuppressive factors, such as IL-10. Although physical exercise might decrease proinflammatory status in WAT, it remains uncertain whether exercise affects the adipocytes or the infiltrated macrophages. The purpose of the current study was to analyze the effects of acute and chronic swimming exercises on the inflammatory status and insulin signaling of the adipose tissue fractions, stromal-vascular fraction (SVF) and adipocytes.

Materials and methods: The effects of acute and chronic exercise protocols were investigated on circulating IL-6 and TNF- α levels by an enzyme-linked immunosorbent assay, insulin signaling proteins and cytokine expression by Western Blot analysis and mRNA cytokine levels by Real Time in WAT fractions of diet-induced obesity (DIO). Additionally, we also observed macrophage infiltration and polarization in WAT through immunohistochemistry.

Results: The results showed that acute exercise reduced the proinflammatory status mainly in SVF evidenced by reduced expression of MCP-1, TNF- α and IL-1 β , without changing WAT macrophage infiltration. In this line, the chronic exercise displayed the same results and also completely reversed the macrophage infiltration into WAT. In parallel, both exercise protocols increase the IL-10 protein content and also promote reduction in circulating TNF- α levels. We also observed higher insulin-induced phosphorylation of IR, IRS-1 and Akt in both fractions in all exercised animals. Our results show that physical exercise in DIO rats induces not only an important suppression in proinflammatory cytokines, but also increases anti-inflammatory cytokines secretion.

Conclusion: Taken together these alterations indicate that acute and chronic exercises contribute to improved inflammatory status and insulin signaling in WAT by different mechanisms. Acute exercise induces only the phenotypic switching from M1 to M2 macrophages. On the other hand, besides improving the polarization, the chronic exercise blunted macrophage infiltration induced by obesity. These data provide considerable progress in our understanding of the molecular events that link physical exercise to an improvement in inflammation and insulin resistance in WAT.

Foam cells formation in human visceral adipose tissues correlates with increase in BMI

H. Shapiro, R. Shako-Levy, N. Bashan, A. Rudich;
Clinical Biochemistry, Faculty of Health Sciences, Ben Gurion University, Israel.

Background and aims: Inflammation is one of the mechanisms proposed to link obesity with its associated morbidities, including type 2 diabetes and

cardiovascular diseases. Macrophages accumulate in adipose tissues in proportion to obesity and adipose tissue macrophages (ATMs) suggested to promote insulin resistance and type 2 diabetes. We aimed to study the molecular characteristics of human lipid-laden ATMs and correlate it with the clinical parameters associated with the metabolic syndrome.

Materials and methods: Histological sections of human fat biopsies (visceral and sub-cutaneous adipose tissues) were stained with CD68 and hematoxylin-eosin to identify macrophages and lipid-laden ATMs, respectively. Using flow cytometry, we developed a technique to detect and quantify lipid-laden ATMs by gating on CD45⁺, CD14⁺ cells and analyze their lipid profile by staining with Bodipy for neutral lipids.

Results: We found in human fat biopsies a sub-group of macrophages loaded with lipids, which we named adipose tissue (AT) foam cells, as they resemble foam cells found in atherosclerotic lesions. AT foam cells accumulated in crown-like structures areas surrounding the adipocytes. Foam cells were detected in fat biopsies of obese and diabetic but not lean patients and were more evident in visceral comparing to subcutaneous adipose tissues. In diabetic patients AT foam cells were associated with matrix deposition in crown-like structures. Based on flow cytometry analyses, we found that formation of AT foam cells correlated with increase in the BMI of the patients. For example, for BMI 20.1: 0.05% AT foam cells, for BMI 40: 12.4% AT foam cells, for BMI 43.7: 24.4% AT foam cells and for BMI 50, 53.7% AT foam cells were found.

Conclusion: We discovered in adipose tissues of obese, diabetic but not lean patients formation of AT foam. Higher frequency of AT foam cells correlated with increase in the BMI and in visceral adiposity of the patients. We plan to further study the molecular characteristics of AT foam cells and correlate them with other clinical parameters associated with obesity and its related morbidities. Together, using these approaches, we will be able to determine whether foam cells generation in visceral adipose tissues of obese patients contribute to adipose tissues insulin resistance and promoting the systemic insulin resistance and type 2 diabetes.

Dietary fatty acids activate TLR4 and the inflammasome in dendritic cells and adipocytes - implications for diet-induced obesity

C.M. Reynolds¹, F.C. McGillicuddy¹, K.A. Harford¹, K.H.G. Mills², H.M. Roche¹;

¹Conway Institute, University College ²Immune Regulation Research Group, Trinity College Dublin, Ireland.

Background and aims: Adipose tissue inflammation has been linked with a plethora of pro-inflammatory cytokines which are thought to play a key role in the attenuation of insulin sensitivity. Several recent studies suggest a functional role for the NLRP3 inflammasome, a protein complex involved in processing IL-1 and IL-18, in obesity, with specific roles in adipogenesis and development of adipocyte insulin resistance (IR). However the critical metabolic trigger of inflammasome activation within the context of diabetes remains elusive.

Materials and methods: C57BL/6J mice received a HFD for 0-16 weeks. Glucose tolerance test (GTT) determined IR. Plasma, adipose and bone marrow (BM) were harvested. Stromal vascular fraction (SVF) cells were isolated from adipose and analyzed by flow cytometry for CD11c⁺CD11b⁺F4/80⁺ DC. BM cells were cultured in RPMI supplemented with GM-CSF for 7 days. DC were stimulated with LPS (100ng/ml) and harvested for protein and RNA. BMDC were primed for 3h with either LPS (100ng/ml) or PA (200 μ M) to induce pro-IL-1 β production followed by 1h ATP stimulation (5mM), a well characterised activator of the inflammasome.

Results: We demonstrate that dietary fatty acids directly prime and activate the NLRP3 inflammasome via TLR4, promote recruitment/activation of adipose DC (CD11c⁺CD11b⁺F4/80⁺) in high-fat diet (HFD) induced IR. HFD-derived BMDC exhibited greater LPS responsiveness with increased IL-1 β secretion, enhanced IL-1R1, TLR4 and caspase-1 expression. Adipocyte/HFD-derived BMDC co-culture enhanced adipocyte IL-1 β secretion, caspase-1 activity, with greater adipocyte IR, versus age-matched chow fed controls. Complimentary *in vitro* experiments demonstrate saturated fatty acid (SFA) treatment (palmitic acid; PA) enhanced cytokine expression, which was attenuated by caspase-1 and TLR4 inhibition in BMDC. Pre-priming of BMDC with PA led to a dramatic rise in IL-1 β concentrations following exposure to ATP, a potent inflammasome activator.

Conclusion: SFA represent potential metabolic triggers priming the inflammasome, promoting adipocyte inflammation and IR, suggesting a direct effect of SFA on inflammasome activation in diet-induced obesity.

The impact of hyperinsulinaemia on the serum IL-12/p40 subunit concentrationA. Nikolajuk^{1,2}, A. Adamska¹, M. Karczewska-Kupczewska¹, N. Kaminska¹, M. Zielinska¹, M. Górski¹, I. Kowalska¹, M. Strączkowski¹;¹Endocrinology, Diabetology and Internal Medicine, Medical University of Białystok, ²Department of Prophylaxis of Metabolic Diseases, Institute of Animal Reproduction and Food Research of Polish Academy of Sciences, Białystok, Poland.

Background and aims: Numerous studies indicate an association between low-grade chronic inflammation and predisposition to type 2 diabetes and atherosclerosis. IL-12 is a proinflammatory cytokine with proatherogenic properties. IL-12 is a disulfide-linked, 70kDa (p70) heterodimeric glycoprotein composed of a 40kDa (p40) subunit and a 35kDa (p35) subunit. Many data reported higher levels of p40 subunit than total IL-12. The aim of the present study was to investigate the influence of hyperinsulinemia on serum p40 subunit.

Materials and methods: Our study involved 35 young (age: 24.31±2.81 years), apparently healthy men with normal glucose tolerance. Anthropometric measurements, blood biochemical analysis and euglycemic hyperinsulinemic clamp were performed in the studied group.

Results: The serum concentrations of p40 was significantly lower after the clamp than the baseline state ($p<0.05$). The change in IL-12/p40 during the clamp was already to the steady-state insulin (SSI) concentrations ($r=0.35, p=0.037$) - the higher SSI the greater decrease in serum IL-12/p40. We found inverse correlations between post-clamp serum p40 and total cholesterol and LDL-cholesterol ($r=-0.34, p=0.049$ and $r=-0.46, p=0.006$, respectively). A significant association between basal and post-clamp p40 subunit and lymphocyte cell count ($r=0.35, p=0.037$ and $r=0.45, p=0.006$, respectively) and significant negative correlations with neutrophil cell count ($r=-0.41, p=0.014$ and $r=-0.51, p=0.002$, respectively) was observed in the studied group.

Conclusion: Our data indicated that hyperinsulinemia decreased serum IL12/p40 concentration.

The expression of interleukin-33 and its receptor ST2 are increased in obese adipose tissue and predominantly found in endothelial cellsT.M. Stulnig¹, B. Wernly¹, S. Demyanets², C. Kaun², M. Hammerle³, B. Hantusch³, A. Neuhofer³, M. Keck³, O. Azsmann³, G. Prager³, J. Wojta², M. Zeyda¹;¹Clinical Division of Endocrinology and Metabolism, ²Clinical Division of Cardiology ³Medical University of Vienna, Austria.

Background and aims: Obesity is associated with a chronic inflammation of the adipose tissue, which contributes to obesity-associated complications such as insulin resistance and Type 2 diabetes. Interleukin(IL)-33, a novel member of the IL-1 family, acts via its receptor ST2 and is involved in the pathogenesis of inflammatory disorders including atherosclerosis and heart disease. IL-33 has been demonstrated to promote endothelial cell inflammatory response but also Th2 and M2 polarization of T cells and macrophages, respectively. IL-33 and its receptor ST2 have been shown to be expressed in human and murine adipose tissue, but alterations in obesity as well as a possible role in adipose tissue inflammation has not been investigated yet.

Materials and methods: We utilized murine obesity models as well as obese and lean individuals to investigate the impact of obesity on IL-33 and ST2 gene and protein expression levels in adipose tissue and blood and their correlation with obesity-associated parameters. By fractionation of adipose tissue we examined the cellular sources and location of IL-33 and ST2.

Results: We show that IL-33 and ST2 are markedly elevated in obese visceral and subcutaneous adipose tissue of humans and in diet-induced obese mice, but not in leptin receptor-deficient obese mice. Also soluble ST2, but not IL-33 plasma levels were elevated in obesity. As the main source for IL-33 within the adipose tissue, we identified endothelial cells. In human adipose tissue ST2 was almost exclusively found on endothelial cells, indicating these cells as the main target of IL-33 action. In contrast, T-cells were the predominantly ST2-expressing cell in mice. In human omental adipose tissue of obese IL-33 expression strongly correlated with leptin expression, while no other significant correlation with inflammatory, metabolic, and anthropometric data was detectable.

Conclusion: IL-33 expression in adipose tissue is regulated by obesity and endothelial cells are the main cell type involved in expression and, in humans, also action of IL-33. Thus, the adipose tissue microvasculature could participate in obesity-associated inflammation and related complications via IL-33/ST2.

Implication of the inflammatory kinase Tpl2 in the deleterious effects of cytokines and macrophages on adipocytes functionsJ.-F. Tanti^{1,2}, F. Ceppo^{1,2}, T. Grémeaux^{1,2}, J. Jager^{1,2}, O. Bezy³, Y. Le Marchand-Brustel^{1,2}, M. Cormont^{1,2};¹Team Cellular and Molecular Pathophysiology of Obesity, INSERM U 895, ²Université de Nice Sophia Antipolis, Nice, France, ³Joslin Diabetes Center, Boston, USA.

Background and aims: Adipose tissue (AT) inflammation and dysfunction are involved in the development of the complications of obesity. In obesity, AT is infiltrated by inflammatory macrophages that contribute to the production of cytokines. These cytokines alter the functions of adipocytes leading to a decrease in insulin signaling and action and to an increase in lipolysis. Further, free fatty acids produced by dysfunctional adipocytes have an inflammatory effect on macrophages. This cross-talk may sustain the inflammation of the adipose tissue. We have recently reported that the MAP3 kinase Tpl2 was a new inflammatory kinase involved in the deleterious effect of cytokines on adipocytes function. The aim of the present study was to determine the implication of Tpl2 in the cross-talk between macrophages and adipocytes and in the deleterious effect of macrophages on adipocytes function.

Materials and methods: The expression of Tpl2 in AT macrophages was measured by real-time PCR after FACS sorting. Adipocytes were cultured with macrophages or incubated with conditioned medium from macrophages treated with a concentration of LPS that is compatible with the concentration found in obese mice or patients. All these treatment was performed in the absence or presence of a Tpl2 inhibitor in order to assess the implication of Tpl2 pathway on cytokines production, lipolysis, insulin signaling and action.

Results: We found that Tpl2 expression was increased in AT of obese mice and patients and that treatment of adipocytes with TNF-alpha or IL-1beta increased its expression in adipocytes. Further by FACS sorting, we demonstrated that Tpl2 expression was increased in CD11c+ macrophages from AT of obese mice. A co-culture between adipocytes and macrophages enhanced the expression and production of inflammatory cytokines and the lipolysis and decreased insulin signaling in adipocytes. We found that the pharmacological inhibition of Tpl2 in the co-culture markedly suppressed the production of cytokines and free fatty acids and partly restored the insulin signaling in adipocytes. A conditioned medium of macrophages treated with low dose of LPS inhibited insulin signaling and glucose transport in adipocytes. Treatment of macrophages with a Tpl2 inhibitor markedly reduced the deleterious effect of the conditioned medium on insulin signaling and action in adipocytes.

Conclusion: Our results indicate that the Tpl2 pathway may constitute a mediator in the cross-talk between adipocytes and macrophages in adipose tissue leading to sustained inflammation. Inhibition of this pathway may reduce the production of inflammatory cytokines by the macrophages and improved adipocytes insulin signaling and functions.

The effect of age versus high-fat feeding on adipose tissue macrophage accumulation and immunogenicity

K.A. Harford, F.C. McGillicuddy, C.M. Reynolds, O. Finucane, H.M. Roche; Nutrigenomics Research Group, UCD Conway Institute, Dublin, Ireland.

Background and aims: High-fat diet (HFD)-induced obesity is associated with progressive infiltration of macrophages into adipose tissue. These adipose tissue macrophages (ATM) are referred to as classically-activated M1 macrophages and are potent sources of the cytokines IL-1 β , IL-6 and TNF α , which augment adipose tissue inflammation. While HFD undoubtedly drives macrophage recruitment, age is another factor that may play a role in this phenomenon. In this study we hypothesized that macrophage recruitment into adipose may be evident with age but the inflammatory

phenotype of ATM would be attenuated due to lack of pro-inflammatory high-fat insult.

Materials and methods: C57BL/6 mice (6–8wks old) were fed HFD (45% palm oil) or were maintained on a chow diet (CD) (10% palm oil) for 16 weeks. Glucose (GTT, 1.5g/kg glucose) and insulin (ITT, 0.75U/kg) tolerance tests were performed at baseline (6–8wks) and after dietary interventions (6mths old). Adipose was harvested from mice at baseline and after chow or HFD and cytokine secretion from adipose explants monitored after 24h in culture. Epididymal adipose tissue (EAT) was harvested at baseline or after 16wks HFD/CD. Presence of M1 macrophages (F4/80⁺CD11b⁺CD11c⁺) in the stromal vascular cells (SVCs) of adipose was analyzed by flow cytometry. Separately, a population of F4/80⁺CD11b⁺ cells were isolated from the SVCs of HFD/CD fed mice after 16wks dietary intervention and were cultured for 24hours *ex vivo* prior to RNA isolation. mRNA expression of inflammatory genes was assessed by real-time PCR. SVCs isolated from chow-fed or HFD-fed derived adipose tissue were co-cultured with 3T3L1 adipocytes for 48h. Insulin stimulated glucose transport into adipocytes and mRNA expression of key inflammatory and insulin signalling genes were monitored by real-time PCR.

Results: M1 macrophage recruitment increased equivalently from baseline ($4.53 \pm 1.7\%$) after HFD ($18.75 \pm 1.3\%$) and CD ($15.63 \pm 1.2\%$). Development of IR was only evident in HFD-fed animals with preservation of glucose tolerance in CD mice. Cytokine secretion from adipose tissue explants was markedly higher after HFD compared to CD despite presence of similar numbers of ATM. F4/80⁺CD11b⁺ cells isolated from mice fed a HFD exhibited greater mRNA expression of pro-inflammatory M1 markers IL-6, TNF α , IL-1 β , IL-18 and Nos2 compared to CD-derived cells. Furthermore co-culture of SVCs derived from HFD, but not chow-fed mice, with 3T3L1 adipocytes resulted in significantly reduced insulin-stimulated glucose uptake into adipocytes ($p < 0.05$) and enhanced adipocyte IL-6 and reduced IRS-1 and adiponectin mRNA.

Conclusion: In the present study we demonstrate that both obesity and age are associated with increased infiltration of M1 macrophages into adipose tissue but development of IR was only evident in high fat-fed cohorts. Further characterization revealed that the immunogenic phenotype of recruited ATM and adipose tissue explants was significantly higher after HFD compared to CD. Furthermore, SVCs from high-fat fed animals induced a greater degree of IR in co-cultured adipocytes compared to chow-derived cells. These results suggest that it is not the number of macrophages that infiltrate adipose that dictates severity of IR but the immunogenic phenotype of the recruited cells

Endocannabinoids regulate adipokine production and the immune balance of omental adipose tissue in human obesity

Q. Ge¹, E. Maury¹, J. Gérard¹, L. Noël¹, R. Detry², B. Navez², S.M. Brichard¹;

¹Unité d'Endocrinologie et Métabolisme, ²Abdominal Surgery Unit, l'Université Catholique de Louvain, Bruxelles, Belgium.

Background and aims: The endocannabinoid system (ES) is involved in regulation of energy homeostasis and the metabolism of lipids and glucose through central and peripheral pathways. Blockade of the cannabinoid type 1 (CB₁) receptor with Rimonabant in obese patients promoted significant decrease of bodyweight and waist circumference, and improvement in cardiovascular risk factors. The ensuing rise of circulating adiponectin (ApN) levels was not merely explained by weight loss and suggested specific improvement of adipose tissue function and immune regulation. The aim of this work was to address whether modulation of CB1 directly regulates the production of ApN and other potential adipokines by omental adipose tissue (OAT) of obese subjects.

Materials and methods: OAT was obtained from 30 obese subjects (BMI, 40.6 ± 1.3 kg/m²) undergoing abdominal (mainly bariatric) surgery. Tissue explants (2–3 mm³) or isolated adipocytes or stromal-vascular cells (SVC) were cultured for 24 h with or without a selective CB1 antagonist or a selective agonist (arachidonyl-2-chloroethanolamide; ACEA). mRNA levels of adipokines, which were previously found to be differentially regulated between lean and obese subjects, were measured by RTQ-PCR, and ApN secretion in medium was quantified by RIA. Phosphorylation of p38 Mitogen-activated protein kinase (MAPK) was analysed by Western blot.

Results: In adipose tissue explants, the CB1 blocker rimonabant upregulated ApN gene expression by ~40%. mRNA abundance of omentin which, like ApN, exhibits insulin-sensitizing properties and is decreased in obesity was upregulated as well (~ +70%). Conversely, mRNA levels of 2 pro-inflammatory cytokines, macrophage inhibitory protein (MIP)-1 β and interleukin (IL)-7 were downregulated (~-26% and ~-32%, respectively). We next examined where these effects took place within OAT. CB1 expression was roughly similar in both cellular fractions. In isolated mature adipocytes, blockade of CB1 reproduced the increase of ApN mRNA and the decrease of IL-7 mRNA while inducing a moderate but significant increase of ApN secretion into the medium (+20%). In isolated SVC, gene expression of omentin, which is restricted to this fraction, was augmented while that of MIP-1 β was diminished. To decipher the mechanisms leading to ApN regulation by the ES, we investigated several signalling pathways in adipocytes. The upregulation of ApN by CB1 blockade was unaltered by inhibiting cAMP production. Unlike the blockade, activation of CB1 by ACEA did down-regulate ApN gene expression, an effect reversed by specific inhibitors of p38MAPK (but not of JNK or ERK1/2). Western blot analysis further confirmed that ACEA did actually increase p38MAPK phosphorylation in adipocytes.

Conclusion: The ES directly regulates the immune balance of OAT in human obesity. Specifically, blockade of CB1 attenuates the inflammatory state in both cellular fractions of OAT either by increasing ApN and omentin production or decreasing mRNAs of MIP-1 β and IL-7. ApN regulation by the ES partly involves p38MAPK.

N-3 polyunsaturated fatty acids lead to an increased production of lipid derived adipokines and improve systemic inflammation in severely obese subjects

B.K. Itariu¹, A. Neuhofer¹, D. Mascher², M. Zeyda¹, E. Hochbrugger¹, G. Prager³, T.M. Stulnig¹;

¹Clinical Division of Endocrinology and Metabolism, Medical University of Vienna, ²pharm-analyt Labor GmbH, Baden, ³Division of General Surgery, Medical University of Vienna, Austria.

Background and aims: The systemic inflammatory response to obesity originates in the adipose tissue (AT) and is tightly linked to insulin resistance and type 2 diabetes. Eicosanoids are potent lipid mediators that play a key role in the regulation of inflammation. Such lipid mediators, called lipid-derived adipokines (LDA), are produced by the AT in considerable amounts. Whereas pro-inflammatory eicosanoids deriving mainly of the n-6 polyunsaturated

fatty acid (PUFA) arachidonic acid (AA) have been extensively studied, some highly potent n-3 PUFA-derived LDA and LDA-precursors have been identified only recently. Such novel LDA like 17-hydroxy-DHA (17-HDHA), resolvins and protectins have been showed to promote the resolution of inflammation. Since chronic inflammation could result from a failure to resolve an inflammatory response, we aimed to identify LDA production in AT from severely obese subjects and to investigate whether n-3 PUFA supplementation would impact LDA production, systemic inflammation, and insulin sensitivity.

Materials and methods: Fifty-four severely obese (BMI ≥ 40 kg/m²) non-diabetic patients, supposed to undergo elective bariatric surgery, were treated for two month with either 3,3 g/day highly purified n-3 PUFA (1,8 g EPA/1,5 g DHA) or an equivalent amount of mainly saturated fatty acids as a control, in a randomized, open label controlled clinical study. Compliance was assessed by comparing levels of EPA and DHA in plasma phospholipids before and after treatment by GC/MS. Plasma concentration of inflammation markers such as IL-6 and hsCRP were determined at baseline and at the end of treatment. Concomitantly, 2 h OGTT were performed and insulin sensitivity/resistance indices such as OGIS, CLIX, HOMA-IR were calculated. During the surgical procedure, omental AT samples were collected. LDA concentrations in AT were analysed by solid phase extraction and HPLC-MS/MS. For statistical analyses, we used repeated measures ANOVA, unpaired Student's t-test and Pearson's correlation.

Results: Plasma EPA and DHA levels increased after n-3 PUFA treatment (both $P < 0.001$). The intervention led to a decrease in AA concentration ($P = 0.03$) as well as a consistent improvement of the anti-inflammatory index AA/EPA ($P < 0.001$). Omental AT production of 17-HDHA and Protectin D1 was higher in the n-3 PUFA group ($P = 0.02$ and $P = 0.002$ respectively). Resolvin E1 and Resolvin D1 were only detectable in AT of n-3 PUFA treated patients. In this group we also found a correlation between AT 17-HDHA concentration and CLIX ($r = 0.82$, $P < 0.001$). The treatment lead to a decrease in IL-6 concentration ($P = 0.03$), without affecting hsCRP levels. No treatment-related changes were observed in any of the calculated insulin sensitivity/resistance indices.

Conclusion: Our results show that n-3 PUFA treatment of severely obese patients leads to a shift in LDA towards an increase in the synthesis of anti-inflammatory or resolving lipid mediators and their precursors in AT. These local changes were associated with beneficial effects on systemic inflammation. Although we could not detect any improvement in insulin sensitivity under the given conditions, the anti-inflammatory changes induced by n-3 PUFA may be beneficial in long term treatment.

Decreased lactoferrin expression in adipose tissue and adipocytes in association with obesity

J. Moreno-Navarrete¹, M. Serrano¹, M. Sabater¹, N. Pueyo¹, F.J. Ortega¹, J.I. Rodríguez-Hermosa², G. Pardo¹, W. Ricart¹, J. Fernández-Real¹;

¹Department of Diabetes, Endocrinology and Nutrition (UDEN),

²Department of Surgery, Institut d'Investigació Biomèdica de Girona (IdIBGi), Spain.

Background and aims: Recently, a possible role of lactoferrin in adipogenesis and insulin action has been reported. To gain insight in this role, we aimed to investigate lactoferrin and delta-lactoferrin gene and protein expression in human adipose tissue and adipocytes in association with obesity.

Materials and methods: Lactoferrin and delta-lactoferrin gene expression was measured in 75 visceral and subcutaneous adipose tissue samples, in 16 adipose tissue fractions (Stromal vascular cells (SVCs) and adipocytes) and during adipocyte differentiation in human primary preadipocytes from lean and obese subjects. Lactoferrin protein levels were measured by elisa in adipose tissue and in adipocyte-conditioned media.

Results: Lactoferrin (LTF) gene and protein was expressed in both visceral and subcutaneous adipose tissue at similar levels as other master adipogenic genes such as PPAR γ . LTF gene expression was negatively associated with BMI and fat mass in both subcutaneous and visceral fat depots. In addition, LTF gene expression in subcutaneous adipose tissue was negatively associated with fasting glucose and fasting triglycerides and positively associated with lipogenic genes [FASN ($r = 0.67$, $p < 0.0001$), ACC1 ($r = 0.42$, $p < 0.0001$) and SCD1 ($r = 0.42$, $p < 0.0001$)]. LTF gene expression was significantly increased in adipocytes in comparison with stromal vascular cells (SVCs) (0.034 ± 0.01 vs. 0.001 ± 0.0003 R.U., $p = 0.03$). According with this, lactoferrin

levels increased during human adipocyte differentiation in parallel to adipogenic genes, and its levels were increased in human adipocytes from lean in comparison with obese subjects (0.008 ± 0.002 vs. 0.0007 ± 0.0001 , $p < 0.001$). The inhibition or stimulation of adipogenesis during adipocyte differentiation (with metformin or rosiglitazone administrations) reduced or increased, respectively, lactoferrin levels during adipocyte differentiation. Otherwise, delta-lactoferrin (δ -LTF) was expressed at low levels in human adipose tissue and adipocytes. δ -LTF gene expression was not associated with metabolic parameters, and it was more expressed in SVCs in comparison with adipocytes (0.018 ± 0.004 vs. 0.007 ± 0.002 R.U., $p = 0.03$). In human adipocytes, LTF but not δ -LTF gene expression increased in response to inflammatory conditions (TNF- α and LPS-macrophage conditioned medium) and rosiglitazone treatment. Lactoferrin protein levels in adipose tissue and circulating lactoferrin concentration in adipocyte conditioned medium run in parallel with LTF gene expression.

Conclusion: Lactoferrin gene and protein expression in adipose tissue was inversely associated with obesity, and increase during adipogenesis. These results suggest a beneficial role of lactoferrin improving insulin sensitivity and obesity-associated metabolic disturbances.

Serum concentrations and adipose tissue expression of pigment epithelium-derived factor in obese patients with type 2 diabetes mellitus: the influence of very-low-calorie diet

M. Mraz¹, P. Trachta¹, Z. Stranska¹, Z. Lacinova¹, D. Haluzikova^{1,2}, V. Touskova¹, M. Matoulek¹, S. Svacina¹, M. Haluzik¹;

¹3rd Department of Medicine, ²Department of Sports Medicine, Charles University, Prague, Czech Republic.

Background and aims: Pigment epithelium-derived factor (PEDF) is a novel adipokine and metabolic regulator with diverse effects on glucose homeostasis, inflammation and angiogenesis. The aim of the present study was to explore the possible role of PEDF in the positive metabolic effects of short term very-low-calorie diet (VLCD) in obese patients with type 2 diabetes mellitus (T2DM).

Materials and methods: Thirteen obese females with T2DM and 17 healthy lean sex- and age-matched controls (C) were included into the study. Serum concentrations of selected biochemical, hormonal and immunological parameters were measured by standard laboratory methods. The expression analysis of genes for PEDF, TNF- α , IL-6, IL-8, adiponectin and adiponectin receptor 1 and 2 in subcutaneous adipose tissue (SCAT) was performed by real-time PCR at baseline and after 3 weeks of VLCD (energy intake 2500 kJ/day).

Results: Compared to C group T2DM patients had significantly increased BMI (57.7 ± 2.7 vs. 22.2 ± 0.5 kg/m², $p < 0.001$), fasting glucose (8.51 ± 1.11 vs. 4.58 ± 0.11 mmol/l, $p < 0.001$), insulin (35.3 ± 3.7 vs. 17.3 ± 1.4 mIU/l, $p < 0.001$), CRP (2.25 ± 0.43 vs. 0.32 ± 0.12 mg/l, $p = 0.001$), TNF- α (6.53 ± 0.84 vs. 3.52 ± 0.39 pg/ml, $p = 0.017$), IL-6 (2.34 ± 0.45 vs. 1.01 ± 0.14 pg/ml, $p < 0.001$) and IL-8 (2.53 ± 0.26 vs. 1.67 ± 0.24 pg/ml, $p = 0.018$) and decreased concentrations of adiponectin (16.1 ± 2.0 vs. 26.4 ± 3.2 μ g/ml, $p = 0.012$). Serum PEDF was significantly elevated in T2DM group (16.7 ± 1.6 vs. 10.4 ± 0.5 ng/ml, $p < 0.001$) and correlated positively with BMI ($r = 0.633$, $p < 0.002$), fasting glucose ($r = 0.487$, $p = 0.025$), insulin ($r = 0.698$, $p < 0.001$), HOMA index ($r = 0.750$, $p < 0.001$), CRP ($r = 0.609$, $p = 0.004$) and IL-6 ($r = 0.592$, $p = 0.005$) in a combined population of T2DM and C patients. mRNA expression of PEDF, adiponectin and adiponectin receptor 2 was significantly ($p < 0.05$) reduced in SCAT of T2DM subjects, while no expression change was seen in other investigated parameters. Three weeks of VLCD markedly decreased body weight (57.7 ± 2.7 vs. 48.7 ± 2.3 kg/m², $p < 0.001$) and improved glycemia (8.51 ± 1.11 vs. 6.28 ± 0.64 mmol/l, $p = 0.008$), insulin resistance (HOMA index: 12.8 ± 1.5 vs. 8.1 ± 1.1 , $p < 0.001$) and inflammatory profile (CRP: 2.25 ± 0.43 vs. 1.31 ± 0.29 mg/l, $p = 0.01$; IL-6: 2.34 ± 0.45 vs. 1.53 ± 0.32 pg/ml, $p = 0.009$). PEDF serum concentrations (16.7 ± 1.6 vs. 14.7 ± 1.1 ng/ml, $p = 0.233$) and mRNA expression ($p = 0.113$) showed no significant change after VLCD. The same was true for mRNA expression of other studied factors.

Conclusion: Our results show that serum PEDF is increased in patients with T2DM and obesity and correlates well with nutritional status, parameters of glucose metabolism and inflammatory markers. The lack of change in serum concentrations or mRNA expression after VLCD does not support a significant role of PEDF in the positive metabolic effects of short-term caloric restriction.

Retinol binding protein 4 and osteoprotegerin in patients with type 2 diabetes mellitus: relation to insulin resistance

M. Gorshunskaya¹, Y. Karachentsev¹, E. Jansen², N. Kravchun¹, T. Grinchenko¹, I. Romanova¹, T. Tyzhnenko¹, Z. Leshchenko¹, A. Gladkih¹, A. Pochernyaev¹, Y. Opaleiko¹, L. Atramentova¹, V. Poltorak¹;

¹Endocrinology, SI "V. Danilevsky Institute of Endocrine Pathology Problems of AMS of Ukraine", Kharkiv, Ukraine, ²National Institute for Public Health and the Environment, Bilthoven, Netherlands.

Background and aims: Adipose tissue has been demonstrated to secrete various adipokines that relate to insulin resistance, which has a causal role in type 2 diabetes mellitus (T2DM) and its cardiovascular complications. But understanding of the diverse effects of distinct adipokines and the interactions between these bioactive mediators and osteoprotegerin (OPG) as important regulatory molecule in atherosclerosis are still incomplete. Aim of this study was to evaluate OPG, retinol binding protein 4 (RBP4), other adipokines feature in T2DM patients exploring potential links between the above and insulin resistance parameters.

Materials and methods: A total of 60 patients with T2DM (M/F: 34/26, age 53.93±1.20 yrs, diabetes duration 6.29±0.67 yrs, BMI 32.68±0.77 kg/m², HbA_{1c} 7.06±0.18%) and 21 sex- and age matched healthy control subjects (C) were enrolled in the study. The plasma fasting OPG, adipokines (RBP4, total and HMW adiponectin, vaspin, fetuin-A, resistin, progranulin) and insulin levels were measured with ELISAs. The homeostasis model assessment of insulin resistance (HOMA-IR) and insulin sensitivity (QUICKI) were calculated. Fasting blood glucose, HbA_{1c}, free fatty acids (FFA), lipid profile, high sensitivity CRP(hs-CRP) and IL-6 were determined. The relationship between plasma OPG, RBP4, other adipokines and insulinemic state and metabolic variables was also analyzed (Spearman correlation). Data were presented as mean ± SEM.

Results: Comparing with C significant increase in triglyceridemia (3.29±0.41 vs. 1.56±0.20 mM/L), plasma FFA levels (1.08±0.07 vs. 0.70±0.06 mM/L), HOMA-IR (8.01±0.76 vs. 4.53±0.58) as well as strongly marked decrease in adiponectinemia (total adiponectin 6.22±0.33 vs. 11.80±1.45 mg/L; HMW adiponectin 2.70±0.20 vs. 6.80±0.91 mg/L) and impaired insulin sensitivity (QUICKI 0.47±0.01 vs. 0.50±0.01) were observed in T2DM patients. Plasma RBP4 and OPG levels were significantly ($p<0.001$) higher in T2DM patients in comparison with C (33.28±0.99 vs. 23.01±1.82 mg/L; 493.00±38.80 vs. 312.56±24.78 pg/ml, respectively), hs-CRP and IL-6 were also increased. No differences were observed in resistin, vaspin, fetuin-A and progranulin. In T2DM patients, a strong linear relationship was revealed between OPG value and both progranulin ($r=0.419$, $p<0.002$) and fetuin-A ($r=0.367$, $p<0.001$); there was a correlation with RBP4 ($r=0.253$, $p<0.032$) and resistin ($r=0.301$, $p<0.01$), but not with fasting glucose, HbA_{1c}, insulin or adiponectin (total and HMW). It was identified a relationship of RBP4 to fasting insulin ($r=0.440$, $p<0.004$) and HOMA-IR ($r=0.501$, $p<0.001$) as well as inverse correlation with insulin sensitivity ($r=-0.501$, $p<0.001$). A significant positive correlation was found between RBP4 and progranulin.

Conclusion: In T2DM patients, circulating novel adipokine RBP4 was increased and correlated positively with insulin resistance. Furthermore, it was found significant enhancement of OPG and direct relationship between RBP4 and OPG in circulation. These findings provide a rationale for antidiabetic therapies aimed at lowering plasma RBP4 and OPG levels.

Relationship between retinol binding protein 4 and the risk of cardiovascular diseases

J.M. Kim¹, J.C. Won², K.S. Ko², B.D. Rhee², C.-Y. Park³;

¹Internal Medicine, Sanggye Paik Hospital, Inje University College of Medicine ²Internal Medicine, Sanggye Paik Hospital, Mitochondrial Research Group, Cardiovascular and Metabolic Disease Center, Inje University College of Medicine, ³Internal Medicine, Department of Endocrinology and Metabolism, Sungkyunkwan University School of Medicine, Kangbuk Samsung Hospital, Seoul, Republic of Korea.

Background and aims: Visceral obesity has been suggested to be an independent risk factor for cardiovascular disease (CVD); the role of adipokines in the risk for CVD is less clear. Aim of this study was to investigate the relationship between parameters of visceral obesity and index of CVD risk.

Materials and methods: A cross-sectional analysis of healthy males ($n = 116$) and females ($n = 175$) for evaluation of clinical, laboratory, and anthropo-

metric parameters were undertaken. Abdominal subcutaneous and visceral adipose tissues (SAT and VAT) were measured by computed tomography. Adipokines, including RBP 4 and adiponectin, were determined. The risk for CVD was estimated using the 10-year Framingham Coronary Heart Disease Risk Point scale (10-y FCRP)

Results: The 10-y FCRP was significantly correlated with VAT ($\gamma = 0.123$, $P = 0.049$) and RBP4 ($\gamma = 0.230$, $P < 0.001$), after adjustment for age, gender and BMI. The magnitude of the increased the 10-y FCRP correlated with VAT and RBP4 independent of obesity. In a multiple linear regression model, the serum levels of RBP4 at a given body mass index (BMI) and VAT significantly correlated with the 10-y FCRP ($\beta = 0.123$, $P < 0.001$).

Conclusion: RBP4 is closely associated with the 10-y FCRP. RBP4 appears to provide a link between central obesity and CVD.

743

Effect of short-term hyperglycaemia on the release of adipocytokines from subcutaneous adipose tissue in obese women

V. Stich¹, L. Simonsen², M. Siklova¹, J. Polak¹, J. Bulow²;

¹Department of Sports Medicine, Third Faculty of Medicine, Charles University, Praha, Czech Republic, ²Department Clinical Physiology/Nuclear Medicine, Bispebjerg Hospital, Copenhagen, Denmark.

Background and aims: Diabetes mellitus type 2 is characterized by a pro-inflammatory state associated with an increase of circulating levels of adipocytokines and chemokines. The aim of this study was to investigate whether hyperglycemia per se may increase the release of adipocytokines/chemokines from adipose tissue and, thus, contribute to their increased levels in circulation.

Materials and methods: 9 healthy obese women (age 35+/-5, 1yr, BMI 34+/-4, 9kg/m²) underwent 3 hours' hyperglycemic clamp (HGC) with infusion of somatostatin (to inhibit the endogenous insulin release). The net output of interleukin 6 (IL6) and monocyte chemoattractant protein-1 (MCP-1) from subcutaneous abdominal adipose tissue (SCAAT) was assessed by measurements of arterio-venous differences at rest and during HGC. Blood samples were taken from vein draining subcutaneous abdominal fat and compared with arterial blood samples. Adipose tissue blood flow (ATBF) was assessed using the local Xe-clearance technique.

Results: There was no change of ATBF during HGC (baseline: 1,56+/-1,34 vs 3rd hour of HGC: 1,39+/-0,58 ml/100 g/min, NS). The net outputs of IL-6 and MCP-1 from SCAAT were higher at the end of HGC when compared with baseline (IL 6: 4,2+/-5,28 vs 18,08 +/- 16,44 ml/100 g/min, $p<0,05$; MCP-1: 13,68+/- 31,99 vs. 63,33 +/- 50,73 ml/100 g/min, $p<0,01$). In arterial blood there was a non significant tendency to an increase during HGC for IL-6 (1,70+/-0,89 vs. 3,42+/-3,26 pg/ml, NS) and for MCP-1 (190,28+/- 83,75 vs 211,95+/- 86,83 pg/ml, NS).

Conclusion: Short-term hyperglycemia induces an increase in the release of IL-6 and MCP-1 from SCAAT and, thus, may play a role in the development of the low-grade inflammatory state in adipose tissue associated with diabetes mellitus type 2.

The novel adipokine DPP4 exhibits a stronger release from visceral human adipose tissue compared to subcutaneous adipose tissue in association with insulin resistance

H. Sell¹, R. Schlich¹, M. Willems^{1,2}, F. Ruppe², W.T. Knoefel², M. Blüher³, K.N. Frayn⁴, J. Eckel¹;

¹Paul-Langerhans-Group, German Diabetes-Center, ²Dep. of General, Visceral and Pediatric Surgery, University Hospital Düsseldorf, ³Dept. of Medicine, University of Leipzig, Germany, ⁴Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford University, UK.

Background and aims: By an unbiased proteomic approach, we could recently identify dipeptidyl peptidase 4 (DPP4) as a novel adipokine. DPP4 cleaves N-terminal dipeptides from various substrates including incretins. DPP4 inhibitors prolong the insulinotrophic effect of GLP1 and are in clinical use. DPP4 expression and release increases during adipogenesis of human adipocytes. *In vitro*, DPP4 induces insulin resistance in adipocytes and muscle cells. Human subcutaneous adipose tissue (AT) explants release DPP4 correlating positively with donor BMI, fat cell volume and the metabolic syn-

drome. Circulating DPP4 is significantly increased in obese patients as compared to lean controls and positively correlated with fat cell size and leptin. This study is aimed to 1) assess depot-specific differences of DPP4 release in lean, obese and diabetic patients, 2) measure *in vivo* release of DPP4 from subcutaneous abdominal AT and 3) compare circulating DPP4 levels in insulin-sensitive obese and matched insulin-resistant obese.

Materials and methods: Paired AT explants from the subcutaneous and visceral depot were generated from lean controls and lean diabetic patients as well as obese controls and obese diabetic subjects and DPP4 release was measured by ELISA. Arterio-venous differences in circulating DPP4 were measured across subcutaneous abdominal AT in 17 lean and obese volunteers. 60 morbidly obese patients divided into an insulin-sensitive and insulin-resistant group based on euglycemic hyperinsulinemic clamp and matched for age, gender and body fat, were analyzed for serum DPP4.

Results: DPP4 release was significantly increased from visceral AT explants compared to subcutaneous AT in lean and obese subjects (5-fold and 7-fold, respectively). The highest DPP4 release could be measured from visceral AT of obese diabetic patients compared to lean and non-diabetic controls. A net release of DPP4 from AT also occurred under *in vivo* conditions with obese subjects and women exhibiting an increased net release from subcutaneous abdominal AT. Insulin-sensitive obese patients are characterized by significantly lower circulating DPP4 as compared to obesity-matched insulin-resistant patients. In this cohort, DPP4 positively correlates with the amount of visceral AT, HbA1c, % macrophages in omental AT and adipocyte size. DPP4 is not correlated to total body fat and the amount of subcutaneous AT.

Conclusion: DPP4 is a novel adipokine with higher release from visceral adipose tissue that is particularly pronounced in obese diabetic patients. In obese patients, circulating DPP4 is associated with insulin resistance and correlated with visceral AT mass, enlarged adipocytes and adipose tissue inflammation. Our data suggest that DPP4 might be a biomarker for visceral obesity and the metabolic syndrome.

Serum visfatin is differentially regulated by insulin and non-esterified fatty acids in healthy men

I. Kowalska, M. Karczewska-Kupczewska, A. Adamska, A. Nikolajuk, A. Lebkowska, N. Kaminska, M. Zielinska, E. Otziomek, M. Górski, M. Strączkowski;
Endocrinology, Diabetology and Internal Medicine, Medical University, Białystok, Poland.

Background and aims: Visfatin is a protein secreted by adipose tissue which was discovered as a protein with insulin-mimetic properties. Experimental and clinical studies demonstrated that visfatin can be involved in the pathogenesis of insulin resistance. It was demonstrated that plasma visfatin is elevated in insulin resistant states i.e. obesity, type 2 diabetes mellitus and polycystic ovary syndrome. In vitro study showed that insulin inhibits visfatin release from adipocytes. The aim of the present study was to evaluate serum visfatin concentration during hyperinsulinemia (6-hours hyperinsulinemic euglycemic clamp) and then during insulin resistant conditions caused by an acute elevation of NEFA (6-hours hyperinsulinemic clamp combined with Intralipid-heparin infusion).

Materials and methods: The study group consisted of 19 apparently healthy male volunteers (mean age 25 ± 7 years, BMI 24.3 ± 3 kg/m²). Clinical examination, anthropometric measurements, OGTT, plasma lipids and liver enzymes activity were measured. Subjects underwent 6h euglycemic hyperinsulinemic clamp and after one week 6h hyperinsulinemic euglycemic clamp combined with Intralipid-heparin infusion. Measurements of serum visfatin during both clamp studies were performed.

Results: 6-hours of insulin infusion during clamp resulted in significant decrease in serum visfatin concentration ($p=0.0057$), however after 2h there was no change in serum visfatin concentration. Concomitant 6-hours Intralipid-heparin infusion which caused a significant increase in NEFA concentration ($p<0.0001$), resulted in marked increase in serum visfatin ($p=0.00035$) which was already observed after 2 hours of Intralipid infusion ($p=0.00028$). Serum visfatin during clamp study after 2h and 6h of Intralipid infusion were significantly higher than the respective values during clamp study without elevation of NEFA (both $p<0.0001$). The increase of serum visfatin during Intralipid infusion (delta visfatin) was positively related to body weight ($r=0.54$, $p=0.016$), %body fat ($r=0.48$, $p=0.036$) and gamma glutamyl transpeptidase ($r=0.56$, $p=0.011$).

Conclusion: Our data show that plasma visfatin is differentially regulated by insulin and NEFA. One might suggest that induction of insulin resistance by NEFA suppress insulin inhibition of visfatin production by adipose tissue, resulting in plasma visfatin increase in insulin resistant conditions.

Molecular mechanism of the insulin sensitizing adipokine vaspin

J.T. Heiker¹, N. Klötting¹, P. Kovacs¹, B. Küttner², N. Sträter², S. Schultz³, M. Kern¹, M. Stumvoll¹, M. Blüher¹, A.G. Beck-Sickingher³;

¹Department of Internal Medicine, ²Center for Biotechnology and Biomedicine, ³Institute of Biochemistry, University of Leipzig, Germany.

Background and aims: Obesity significantly increases the risk of developing type 2 diabetes mellitus, hypertension, coronary heart disease, stroke, and several types of cancer. Vaspin (visceral adipose tissue-derived serpin) was identified as an adipokine with insulin-sensitizing effects, which is predominantly secreted from visceral adipose tissue in a rat model of type 2 diabetes. Recently, we reported that elevated vaspin serum concentrations are associated with obesity and impaired insulin sensitivity in humans. Therefore, it has been postulated that increased vaspin expression and secretion could represent a compensatory mechanism associated with obesity, severe insulin resistance, and type 2 diabetes. Although, antiprotease properties have been suggested as mechanism of vaspin action, until now a protease substrate of vaspin has not been identified.

Materials and methods: We recombinantly expressed human vaspin for crystallization and *in vitro* protease inhibition screenings. C57BL/6J and db/db mice were treated with recombinant vaspin to investigate vaspin effects on glucose tolerance and insulin sensitivity. Expression of vaspin and the target protease were investigated in tissue samples using immunohistochemistry and in human serum samples.

Results: Here, we show that the crystal structure of vaspin confirms the typical serpin structure and suggests a protease target. We find that vaspin is expressed in pancreatic beta cells and inhibits a member of the kallikrein family with a high specificity via typical serpin mechanism *in vitro*. This is the first identified target of vaspin. Consistent with a potential insulin protective role of vaspin, plasma insulin concentrations in response to glucose are higher in mouse models treated with recombinant vaspin compared to controls explaining the glucose lowering effect of vaspin. Patients with type 2 diabetes show significantly lower kallikrein serum concentrations. Together with increased vaspin expression in obesity and type 2 diabetes these data corroborate the vaspin-kallikrein system as a physiological compensation mechanism in the metabolically challenged state of obesity and insulin resistance.

Conclusion: Our results suggest the vaspin-kallikrein system as a potential novel target for anti-diabetic treatment strategies.

Adiponectinaemia, metabolic status, insulin secretion and insulin resistance in obese women: influence of weight loss

J. Silva-Nunes^{1,2}, L. Duarte¹, A. Oliveira², A. Melão², M. Brito², L. Veiga²;

¹Endocrinology Department, Curry Cabral Hospital, ²Escola Superior de Tecnologia da Saúde de Lisboa, Lisbon, Portugal.

Background and aims: Obesity is strongly associated with type 2 diabetes mellitus and prediabetes. Loss of the excessive fat mass is expected to improve glucose metabolism. Adiponectin is an adipokine which levels increase with fat mass loss. AIMS: 1) To compare variation (Δ) in adiponectin levels, in insulin secretion (IS) and insulin resistance (IR) indexes, and in anthropometric parameters and metabolic status changes in obese women during weight loss program, according to their initial status; 2) to assess the association between changes in adiponectin levels, IS and IR indexes with those in anthropometric parameters.

Materials and methods: We studied 100 premenopausal obese women anthropometrically characterized. They were submitted to fasting blood sample collection, followed by an oral glucose tolerance test (oGTT). We used one index of IR (homeostatic model -HOMA-IR), one of insulin sensitivity (Matsuda formula) and two IS indexes (homeostatic model -HOMA%beta and insulinogenic index -INS-i). Women entered in a weight loss program and were reassessed for all parameters after 6 and 12 months.

Results: Patients were characterized by mean age=34.1±8.2 yrs, BMI=43.6±8 Kg/m², fat mass=54±15.1 Kg, waist circumference=117.7±15.2cm, waist:hip ratio (WHR)=0.88±0.08, adiponectin=6.86±3.21µg/ml, Matsuda=3.69±2.54, HOMA-IR=4.42±3.65, HOMA%beta=262.1±174.9 and INS-i=24.2±20.2. Normoglycemia (NG) was present in 71 patients, prediabetes in 19 and diabetes in 10. Eighty six patients were reassessed at month 6 and 67 accomplished the 12 months follow-up. No difference between metabolic status groups were observed for anthropometric or adiponectin variation between baseline and months 6 or 12. There was a significantly difference in metabolic status characterization between baseline and month 6 ($p<0.001$) and between baseline and month 12 ($p<0.001$). Between baseline and month 6 we observed that Δ HOMA-IR was positively correlated with Δ waist ($p<0.001$; $r=0.475$) and Δ fat mass ($p<0.001$; $r=0.579$); Δ Matsuda were negatively correlated with Δ waist ($p<0.001$; $r=-0.473$), Δ WHR ($p=0.006$; $r=-0.333$) and Δ fat mass ($p<0.001$; $r=-0.521$); Δ INSi were negatively correlated with Δ waist ($p<0.001$; $r=-0.427$), Δ WHR ($p=0.001$; $r=-0.385$) and Δ fat mass ($p=0.002$; $r=-0.379$); we found a direct correlation between Δ adiponectin and Δ Matsuda ($p=0.003$; $r=0.361$). Considering variations between baseline and month 12, we observed that Δ HOMA-IR was positively correlated with Δ waist ($p<0.001$; $r=0.792$), Δ WHR ($p<0.001$; $r=0.547$) and Δ fat mass ($p<0.001$; $r=0.76$); Δ Matsuda were negatively correlated with Δ waist ($p=0.002$; $r=-0.479$), Δ WHR ($p=0.015$; $r=-0.393$) and Δ fat mass ($p=0.005$; $r=-0.442$). Δ adiponectin was negatively associated with Δ waist ($p<0.001$; $r=-0.448$) and Δ fat mass ($p<0.001$; $r=-0.568$); however it was independently and inversely correlated with Δ HOMA-IR ($p=0.020$; $r=-0.367$).

Conclusion: In weight loss programs, obese women lose fat mass (with a subsequently increase in insulin sensitivity and insulin secretion) independently from their initial metabolic status. Adiponectin levels parallels insulin sensitivity indexes during the process of weight reduction, independently from the amount of fat mass loss. That might indicate a direct insulin-sensitizing effect of adiponectin.

748

Adiponectin improves endothelial dysfunction caused by elevated FFAs levels, partly through cAMP-dependent pathway

B. Wang, Y.R. Yu, L.N. Han;

Endocrinology and Metabolism, West China Hospital, Chengdu, China.

Background and aims: Elevation in circulating free fatty acids (FFAs) is a characteristic metabolic abnormality of the insulin-resistant state, which may be causally related to the onset and progression of endothelial dysfunction. Adiponectin may improve endothelial function in obese rats by reducing oxidative/nitrative stress and regulation of eNOS activity. However, whether adiponectin may protect endothelial cells and attenuate endothelial dysfunction caused by elevated FFAs concentration remains unknown. The current study aimed to determine whether adiponectin may independently improve

the endothelial dysfunction caused by high FFAs concentration and the role of cAMP in the action of adiponectin on endothelial cell.

Materials and methods: Male Sprague-Dawley rats (10 weeks old) thoracic aortas were isolated then cut into four rings of 3-mm length, and was incubated in organ bath contained 20ml of Krebs-Henseleit buffer with different agents separately: 800µmol/L FFA (F, n=14); 800µmol/L FFA+ 2µg/ml adiponectin (A, n=14); 800µmol/L FFA+ 2µg/ml adiponectin + 200µmol/L adenylate cyclase inhibitor dideoxyadenosine (D, n=7); blank control (N, n=10). After 2h of incubation, the aortic rings were precontracted with norepinephrine (0.1µmol/L), then the rings were exposed to cumulative concentration of Acetylcholin (Ach, 10^{-9} - 10^{-5} mol/L) or sodium nitroprusside (SNP, 10^{-10} - 10^{-6} mol/L). Endothelial dysfunction was defined as a reduced vasorelaxation in response to Ach with a normal response to SNP. The NF-κB expression was evaluated immunohistochemically in rat aortic section.

Results: Acetylcholine caused a concentration dependent vascular relaxation in all pre-constricted aortic rings. At the maximal concentration, Ach induced (96.0±2.9)% of vasorelaxation in the N group, indicating well preservation of endothelial function during our procedure. The vasorelaxation was significantly reduced in the F group in comparison with the N group [(60.9±6.7)vs (96.0±2.9)% ($p<0.05$)]. Pretreatment of adiponectin dramatically although incompletely restored maximal vascular relaxation response to Ach [(88.5±3.3) vs (96.0±2.9)% ($p<0.05$)]. Furthermore this vascular protective effect was partly abolished by cAMP signal pathway inhibitor dideoxyadenosine, maximal endothelial dependent vasodilation of the D group reduced to (78.4±6.8)% ($p<0.05$). SNP induced vasodilation had no statistical significance among four groups. Increased NF-κB expression was noted in F group when compared with N group. Pretreatment with adiponectin partly decreased NF-κB expression when compared with F group.

Conclusion: This study demonstrated that adiponectin may independently mitigate endothelial impairment caused by high FFA concentration, and this effect was partly abolished by cAMP inhibitor. These finding raised the possibility that adiponectin perform its vascular protective function partly through activating cAMP signaling pathway, subsequently inhibiting NF-κB expression, which is known to play a central role in the regulation of inflammatory reactions in various types of cells.

Maternal adiponectin multimers determine cord blood adiponectin concentrations

J. Vendrell¹, V. Ceperuelo², A. Megia¹, I. Simon¹, R.M. Miralles³,

F. Tinahones², M. Ballesteros³;

¹Hospital Joan XXIII. IISPV. URV. Ciberdem, ²Hospital Clinico Universitario Virgen de la Victoria. Ciberobn, Malaga, ³Hospital Joan XXIII. URV., Tarragona, Spain.

Background and aims: Adiponectin (Adp) is an adipokine that has been proposed to play a role in the modulation of glucose and lipid metabolism in insulin-sensitive tissues. It is secreted into bloodstream in three different multimeric forms (HMW, MMW, LMW) and the amount and distribution of these forms seem to determine its activity. It is present during fetal life and its levels increase markedly until delivery. Little is known about the factors that determine the concentration of the different multimeric forms during fetal life. The aim of this study was to analyze the influence of Gestational Diabetes Mellitus (GDM) on cord blood adiponectin (cb-Adp) concentrations in full term neonates, and their relationship with some clinical and analytical maternal and neonatal parameters.

Material and methods: 212 women with a singleton pregnancy, 132 with normal glucose tolerance (NGT) and 80 with GDM, and their offspring were studied. Women were recruited between 26 and 30 week of pregnancy at the time of the oral glucose tolerance test and were followed-up until delivery. Cord blood (cb) was obtained at delivery. Maternal and neonatal clinical and anthropometrical data were recorded. Total Adp and the multimeric forms of Adp were determined in cb and maternal (m) serum by a human ELISA kit (Multimeric Adiponectin ELISA Kit; Bühlmann, Schönenbuch, Switzerland). Fasting insulin sensitivity was estimated by the homeostasis model assessment of insulin resistance (HOMA-IR). Spearman correlation coefficient was performed to assess the relationship between cb-Adp levels and clinical and analytical parameters. A stepwise linear regression analysis was used to identify the variables independently related to cb-Adp levels.

Results: maternal age, pre-pregnancy BMI, gestational age at delivery, birth weight (BW) and ponderal index (PI) were similar in the NGT and GDM groups. Total and HMW-Adp levels in maternal serum, were lower in the

GDM compared to the NGT group; Insulin concentrations and HOMA-IR were higher in GDM patients. No differences in Adp levels or its multimeric forms were observed in cb of offspring of diabetic mothers compared to NGT ones, but cb-insulin levels were higher in the GDM group. Cb-Total Adp and cb-HMW Adp levels were positively correlated with BW and PI, whereas cb-MMW Adp was negatively correlated with PI. Interestingly, cb-Adp levels and the multimeric forms of Adp were positively correlated with m-Adp concentrations in bivariate analysis and this relationship persisted after adjustment for GDM, age, pre-pregnancy BMI, gain in BMI and HOMA-IR. In the multivariate analysis, m-MMW Adp (B:3.397; $p<0.001$), PI (B:4920.88; $p<0.01$) and m-LMW Adp (B:1.194; $p<0.05$) were independent predictors of cb-Total Adp. m-MMW Adp (B: 2,399; $p<0.001$) and PI (B:3615,10; $p<0.05$) were predictors of cb-HMW Adp; m-MMW Adp (B:1.038; $p<0.001$) and m-HMW Adp (B:-0.225; $p<0.01$) were the best independent predictors of cb-MMW Adp whereas cb-LMW Adp was only independently related to m-LMW Adp (B:1.075; $p<0.001$).

Conclusion: Cb-Adp levels are independently related to m-Adp concentrations and unrelated to the diagnosis of GDM. Maternal multimeric forms of Adp at the beginning of the third trimester are the main independent predictors of the concentrations of cb-Adp and its multimeric forms at delivery.

Cord blood adiponectin is an independent predictor of neonatal adiposity

A. Megia¹, I. Simon¹, V. Ceperuelo², J. Vendrell¹, L. Garrido¹, M. Ballesteros¹,
¹Hospital Joan XXIII. IISPV.URV. Ciberdem, Tarragona, ²Hospital Clínico Universitario Virgen de la Victoria. Ciberobn, Malaga, Spain.

Background and aims: Adiponectin (Adp) is an adipose tissue derived protein that has been proposed to have a role in the modulation of foetal growth. Adp is detectable in cord serum as early as 24 weeks of pregnancy and its levels increase markedly until delivery coinciding with the period of greater adipose tissue accretion. Adp circulates in three different molecular forms, high molecular weight (HMW), medium molecular weight (MMW) and low molecular weight Adp(LMW). The amount and distribution of these forms seem to determine the activity in peripheral tissues. The aim of this study was to analyze the relationship of the different circulating forms of Adp with neonatal adiposity.

Materials and methods: 172 women with a singleton pregnancy, 102 women with normal glucose tolerance (NGT) and 70 women with Gestational diabetes mellitus (GDM) and their offspring were studied. Women were recruited between 26 and 30 week of pregnancy at the time of the 100 g oral glucose tolerance test and were followed-up until delivery. Cord blood (cb) was obtained from the umbilical vein at delivery. Maternal clinical and demographic characteristics, pregnancy outcome and neonatal anthropometric parameters were recorded. Total Adp and the multimeric forms of Adp were determined in cb by a human ELISA kit (Multimeric Adiponectin ELISA Kit; Bühlmann, Schönenbuch, Switzerland). Fasting insulin sensitivity was estimated by the homeostasis model assessment of insulin resistance (HOMA-IR). Neonatal adiposity was assessed by the sum of skinfolds (SS) and the percent of body fat mass (PBFM) according to the formula proposed by Catalano. Spearman correlation coefficient was performed to assess the relationship between cb-Adp levels with neonatal parameters, and stepwise linear regression analysis were developed to identify if cb-Adp levels were independent predictors of birth weight (BW), ponderal index (PI), SS and PBFM. Each parameter was included as dependent variable and cb-Adp with other clinical and metabolic parameters as independent variables.

Results: Fasting glucose levels ($p<0.001$) and HOMA-IR ($p=0.010$) were higher in the GDM group compared to the NGT. Age, gestational age at entry in the study and pre-pregnancy BMI were similar in both groups. In terms of foetal outcome, there was no difference in gestational age at delivery, mean BW, PBFM, SS or PI. Umbilical insulin levels were significantly higher (4.33[2.35-6.87] vs 4.91[3.05-10.30]; $p=0.010$) in infants born from GDM women, whereas no differences were observed in total Adp levels and its multimeric forms. Cb-total and cb-HMW Adp were positively correlated with foetal parameters (BW, PI, SS and PBFM). Also cb-MMW Adp was positively correlated with SS and PI whereas LMW was positively correlated with all the parameters studied except for BW. In a stepwise multiple lineal regression analysis cb-Adp emerged as an independent predictor of PI (B:0.008; $p<0.01$), SS (B:0.068; $p<0.05$) and PBFM (B:0.102 ($p<0.01$)). Other variables include: pre-pregnancy BMI, BMI gain and cb Insulin. To identify which multimeric form was responsible of this association, the same models were developed

with the multimeric forms of Adp instead of Total Adp. cb-LMW and cb-MMW Adp emerged as independent predictors.

Conclusion: cb Adp levels are independent predictors of neonatal adiposity and the lower weight molecular multimeric forms of Adp seem to be the main responsible of this association.

Gender differences in the response of adipose tissue to deleterious effects of high-fat feeding in mice

K. Bardova, P. Janovska, D. Medrikova, Z. Macek Jilkova, M. Rossmeisl, J. Kopecky;
Department of Adipose Tissue Biology, Institute of Physiology, AVCR, v.v.i., Prague, Czech Republic.

Background and aims: Human as well as animal studies demonstrate less severe obesity-related metabolic disorders (metabolic syndrome) including peripheral tissue insulin resistance and dyslipidemia and/or later onset of these adverse conditions in female than in male subjects. However, mechanisms underlying a relatively low susceptibility of females to various components of the metabolic syndrome remain largely unknown. The goal of this study was to assess the role of adipose tissue in high-fat diet-induced impairment of glucose homeostasis in female as compared with male mice.

Materials and methods: Female and male mice of the C57BL/6N strain were fed from weaning either a chow or obesogenic high fat diet (HF; lipids ~35% wt/wt) for 15 or 35 weeks. Metabolic markers and hormones in plasma, glucose homeostasis, adipocyte size, inflammatory markers and cellularity of gonadal (gWAT) and subcutaneous (scWAT) adipose tissue depots were evaluated.

Results: Although HF-fed female mice were leaner as compared with males during the initial 20 weeks of the experiment, the body weight of both sexes equalized subsequently. Thus, at the end of experiment (Week 35), female mice exhibited greater weight gain and fat accumulation than males, a feature that was associated with larger adipocytes in both fat depots of female mice (~1.21-fold and ~1.19-fold increase in gWAT and scWAT, respectively). While adipose tissue macrophage infiltration, assessed as the number of crown-like structures (CLS) formed by aggregated macrophages, in response to HF feeding was in general less frequent in scWAT (Week 35), it was reduced in both fat depots of female as compared with male mice (~3.1-fold and ~2.8-fold reduction in the CLS number in gWAT and scWAT, respectively). Furthermore, later onset of impaired glucose homeostasis and better insulin sensitivity of female mice was associated with higher adiponectin levels in their circulation, largely independent of the type of diet and duration of the treatment (~1.5-fold difference between the sexes).

Conclusion: As compared to males, female mice display increased capacity for adipocyte enlargement in response to a long-term HF feeding, which is associated with a reduced infiltration of adipose tissue by macrophages and better insulin sensitivity in these mice. Our data suggest that adipose tissue expandability and adiponectin levels might play a role in the gender-specific differences in the development of obesity-associated metabolic disorders.

Adiponectin inhibits nerve growth factor function through direct interaction

K. Kimura, Y. Okura, Y. Okamatsu-Ogura, A. Terao;
Graduate School of Veterinary Medicine, Hokkaido University, Sapporo, Japan.

Background and aims: Adiponectin, an adipokine, plays roles in regulation of metabolic effects and also prevents biological activity of some growth factors such as PDGF-BB through their direct interaction. Here, we examined possible interaction of adiponectin with nerve growth factor- β (NGF- β) being known as an adipokine.

Materials and methods: Direct interaction between adiponectin and NGF- β was examined by surface plasmon resonance method. The effect of adiponectin on NGF- β function was assessed by morphological changes in PC12 cells.

Results: Perfusion of increasing concentrations of NGF- β on the surface of full-length adiponectin-bound chip caused specific increase of mass bound, with the dissociation constant (KD) of 1.0×10^{-7} M and NGF- β /adiponectin ratio of 0.6. NGF- β also bound globular adiponectin-bound chip, but re-

duced KD value and the binding ratio. Treatment of PC12 cells with NGF- β , but not adiponectin, induced neurite outgrowth and cell swelling. However, treatment of the cells with NGF- β and adiponectin simultaneously decreased number of cells with neurite and cell size, compared with those of NGF alone. Treatment of the cells with adiponectin, but not NGF- β , increased activity-related site-specific phosphorylation of AMP-kinase α subunit (AMPK α), and the cells expressed Adipo R1 and Adipo R2 mRNAs. Treatment of the cells with siRNA for Adipo R1 and Adipo R2 prevented adiponectin-induced phosphorylation of AMPK α , but failed to affect adiponectin-caused inhibition of NGF- β -induced neurite outgrowth.

Conclusion: The results indicate that adiponectin interacts with NGF- β in solution, thereby inhibits NGF- β -induced neurite outgrowth and suggest that adiponectin modulates NGF- β function in the adjacent regions of adipocytes.

The rab11 effector rab couplin protein (RCP) regulates adiponectin trafficking and secretion in adipocytes

B.P. Carson^{1,2}, J. Maria Del-Bas², S. Mora²;

¹Physical Education and Sport Sciences, University of Limerick, Ireland,

²Cellular and Molecular Physiology, University of Liverpool, UK.

Background and aims: Adiponectin is an adipocytokine secreted by white adipocytes that regulates insulin sensitivity in peripheral tissues. Adiponectin synthesis and secretion is compromised in obesity and diabetes, resulting in decreased circulating serum levels. The intracellular machinery involved in mediating adiponectin release is largely unknown. We previously reported that intracellular adiponectin partially compartmentalises with rab5 and rab11, markers for the early/sorting and recycling compartments respectively. Here we aimed to investigate the role of several rab11 downstream effector proteins in regulating adiponectin trafficking and secretion.

Materials and methods: GFP-tagged rab11-FIP coding vectors were co-expressed with myc-tagged adiponectin into HEK293 cells or into 3T3L1 adipocytes and localisation of adiponectin-myc and FIP proteins was subsequently determined by immunofluorescent microscopy. Stable 3T3L1 cell lines carrying shRNA for RCP and RIP11 were generated by infecting 3T3L1 cells with lentiviral particles carrying FIP specific shRNA sequences or a scramble shRNA. Released and intracellular adiponectin content was determined using an ELISA kit.

Results: Overexpression of wild type rab11-FIP1 (RCP), FIP3 and FIP5 (Rip11) decreased the amount of secreted adiponectin expressed in HEK293 cells ($p<0.05$), whereas overexpression of rab11-FIP2 or FIP4 had no effect. In addition, the expression of RCP and Rip11 mutants unable to bind rab11 altered adiponectin secretion in HEK293 cells ($p<0.05$). This was supported by shRNA-mediated depletion of RCP and Rip11. Importantly, knock down of RCP in fully differentiated adipocytes also increased adiponectin secretion ($p<0.05$) whereas depletion of Rip11 had no effect in adipocytes.

Conclusion: In all, our findings identify RCP as a novel protein involved in the regulation of adiponectin trafficking and secretion through the endosomal compartments of fully differentiated adipocytes.

Adiponectin levels negatively associate with beta cell function in type 1 diabetes, in contrast to leptin and resistin

M.N. Pham¹, H. Kolb², T. Mandrup-Poulsen³, T. Battelino⁴, J. Ludvigsson⁵, P. Pozzilli⁶, M. Roden^{1,7}, N.C. Schloot^{1,7}, European C-Peptide Trial Study Group;

¹Leibniz Institute for Diabetes Research at Heinrich-Heine-University Düsseldorf, Institute for Clinical Diabetology at German Diabetes Center,

²Institute of Molecular Medicine, University of Düsseldorf, Germany,

³Hagedorn Research Institute, Gentofte, Denmark, ⁴University Children's Hospital, Ljubljana, Slovenia, ⁵Division of Pediatrics, Linköping, Sweden,

⁶University Campus BioMedico, Rome, Italy, ⁷Department of Metabolic Diseases, University of Düsseldorf, Germany.

Background and aims: Adiponectin, leptin and resistin are fat tissue derived peptides with regulatory functions on metabolism and the immune system. A protective (adiponectin, leptin) or disease promoting (resistin) activity has been made probably for type 2 diabetes whereas the possible role of these adipokines in type 1 diabetes is unknown. We therefore

searched for an association with β -cell function in the context of a European multi-centre trial.

Material and methods: The European C-Peptide Trial included 118 patients (mean age 20.3 ± 7.5 years, 70 males) within less than 5 years from diabetes diagnosis. All participants underwent a standardised liquid mixed meal tolerance test (MMTT), and serum samples at -5 until 120 min were centrally analysed by multiplex technology for adipokines or standard procedures for metabolic parameters. Differences of C-peptide levels between patient groups were carried out using multiple regression test adjusted for sex, age, diabetes duration, BMI, baseline glucose, HbA1c or baseline C-peptide, where applicable.

Results: Serum concentrations of the three adipokines varied little over the 120 min of the MMTT. Patients were divided by their adipokine levels in subgroups above or below the median level ("higher versus lower"). Higher adiponectin levels ($>10.6 \mu\text{g/ml}$, mean $15.3 \mu\text{g/ml}$) were associated with lower fasting and stimulated C-peptide concentrations than seen in the lower adiponectin $<10.6 \mu\text{g/ml}$, mean $5.9 \mu\text{g/ml}$ subgroup (fasting C-peptide 0.10 vs 0.14 pmol/ml , $p<0.02$; stimulated C-peptide 0.18 vs 0.31 pmol/ml AUC , $p<0.03$). Conversely, higher leptin or resistin levels associated positively with fasting and stimulated C-peptide concentrations ($p<0.04$ for all comparisons). All differences remained significantly after adjustment for baseline metabolic parameters, including baseline C-peptide when analysing stimulated C-peptide (all $p<0.05$). Correlation analyses confirmed the negative association of adiponectin levels with fasting and stimulated C-peptide levels ($p<0.001$) versus positive associations for leptin and resistin (all $p<0.04$). There was no association between serum adiponectin levels and baseline insulin or HbA1c levels.

Conclusion: Serum adiponectin levels negatively associate with β -cell function in patients with type 1 diabetes. Contrary to what is known for type 2 diabetes, adiponectin does not seem to exert a protective effect on disease development in type 1 diabetes. Surprisingly, both leptin and resistin levels correlated with better preservation of β -cell function in early type 1 diabetes which may be mediated by modulation of innate immunity and regulatory T-cell functions by the two adipokines.

Genetic variation in the genes encoding ADIPOQ and PPAR- γ influences on cardio-metabolic risk factors

F. Dzgoeva, S. Butrova, A.V. Ilyin, A. Prokofiev;

Russian Endocrinology Research Center, Moscow, Russian Federation.

Aim: To investigate the effect of single nucleotide polymorphisms in the adiponectin and PPAR- γ genes on cardio-metabolic risk factors.

Materials and methods: Single nucleotide polymorphisms (SNPs) were genotyped for subsequent association studies on BMI, T2D and related metabolic traits in 752 men and women. Persons with no acute disease or severe chronic disorders underwent physical examination. Fasting blood sample was examined: lipids (total cholesterol, HDL-C, LDL-C, TAG), adiponectin (Adp), insulin; HOMA-IR was calculated. We used PCR to determine the 45T>G (rs2241766), 276C>T (rs 1501299) polymorphisms in adiponectin gene and PPAR- γ 2 Pro12Ala polymorphism. Regression analyses were used to find the associations of single nucleotide polymorphisms with cardio-metabolic risk factors.

Results: The frequency of SNPs PPAR- γ Pro12Ala, ADIPOQ +45T>G and +276G>T in the whole study population ($n=752$) and in the obesity subjects ($n=368$) is comparable (0,158 and 152; 0,064 and 0,058; 0,256 and 0,276, respectively). In women the PPAR- γ 2 Ala12 variant plays a protective role in hypercholesterolemia ($p=0,01$). T allele ADIPOQ rs2241766 is significantly associated with reduced risk of obesity ($p=0,004$). In men T allele ADIPOQ rs1501299 is consistently associated with obesity ($p=0,002$), abdominal obesity ($p=0,04$), prandial hyperglycemia ($p=0,002$); G allele ADIPOQ rs 1501299 plays a protective role for HDL cholesterol level ($p=0,047$).

Conclusion: The allelic variation of the genes encoding adiponectin and PPAR- γ is gender-dependently associated with cardio-metabolic risk factors.

Beneficial effects and signalling pathways of AdipoR1/AdipoR2 activation in muscle like exercise and in liver on glucose/lipid metabolism and anti-inflammation

T. Yamauchi, M. Iwabu, M. Iwabu, T. Kadowaki;

Department of Diabetes and Metabolic Diseases, University of Tokyo, Japan.

Background and aims: The fat-derived hormone Adiponectin has been reported to produce a metabolic profile desirable for treating diseases of ageing such as type 2 diabetes and extend lifespan. In this study, we try to identify orally active AdipoR agonists.

Materials and methods: In skeletal muscle, by using muscle-specific AdipoR1 knockout mice, we showed that calcium signalling pathways as well as AMPK/SIRT1, and PGC-1 α are principal modulators of pathways downstream of Adiponectin/AdipoR1, which increase mitochondrial content and function, and ameliorate insulin resistance and glucose intolerance, like exercise. With regard to the liver, we show that hepatocyte-specific disruption of AdipoR1 results in increased molecules involved in gluconeogenesis, while hepatocyte-specific disruption of AdipoR2 results in decreased PPAR α pathways such as decreased molecules involved in fatty-acid combustion including ACO, both of which are associated with insulin resistance. We next try to identify and characterize orally active AdipoR agonists that are 1,000-fold more potent than adiponectin.

Results: One of these compounds, AdipoR agonist (ARA)-1 increases intracellular calcium concentration and PGC-1 α , and also activates AMPK in C2C12 myocytes. On a high-fat diet, ARA-1 activates AMPK and increases molecules involved in mitochondrial biogenesis such as PGC-1 α , Err α and Nrf1, molecules involved in fatty-acid combustion such as MCAD and oxidative stress-detoxifying enzymes in skeletal muscle, which are associated with increased insulin sensitivity, glucose tolerance and exercise endurance. In the liver, ARA-1 also activates AMPK and suppresses molecules involved in gluconeogenesis as well as activates PPAR α pathways such as increased molecules involved in fatty-acid combustion including ACO. In white adipose tissues, ARA-1 suppresses MCP-1. Importantly, in AdipoR1 and AdipoR2 double knockout mice, all these effects are almost completely abolished.

Conclusion: These data suggest that ARA-1 may activate both AdipoR1 and AdipoR2, and also that orally active AdipoR agonists are promising new therapeutic approach for treating diseases of ageing such as type 2 diabetes as exercise-mimetics.

PS 059 Inflammation and oxidative stress

Aspirin inhibition of thromboxane does not affect oxidative stress, nitric oxide metabolites, paraoxonase activity or P-selectin levels in diabetesL.R. Lopez¹, J.R. Batuca², I.J. Muncy¹, I. Garcia De La Torre³, E. Matsuura⁴, P.R.J. Ames⁵;

¹Corgenix, Inc., Broomfield, USA, ²CEDOC Farmacologia, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Portugal, ³Immunology & Rheumatology, Hospital General de Occidente, Zapopan, Mexico, ⁴Cell Chemistry, Okayama University Graduate School of Medicine, Japan, ⁵Haematology & Rheumatology, Airedale General Hospital, Steeton, UK.

Background and aims: Aspirin (ASA) irreversibly inhibits platelet cyclooxygenase, leading to decreased thromboxane-mediated platelet activation/aggregation. We evaluated additional effects of ASA treatment (100mg/day x 7days) on oxidative stress, nitric oxide metabolites, P-Selectin, paraoxonase 1 (PON1) activity and anti-HDL antibodies in diabetes mellitus (DM).

Materials and methods: Serum and urine were obtained before ASA ingestion (baseline) and after 7 days (post-ASA) from 73 DM (mean age 54.3 years, mean disease duration 9.6 years) and 86 age/sex matched healthy controls. Urinary 11dhTxB2 and 8-isoPGF2 α , and serum P-Selectin, IgG anti-HDL antibodies were measured by ELISA. Serum nitrite (NO₂⁻) and nitrate (NO₃⁻) by modified Griess reaction and PON1 activity by para-nitrophenol formation.

Results: Compared to baseline controls, baseline DM had higher mean levels of 11dhTxB2 (3,665 \pm 2,465 vs 2,450 \pm 1,572 pg/mg creatinine, $p=0.002$), 8-isoPGF2 α (1,457 \pm 543 vs 1,009 \pm 412 pg/mg creatinine, $p<0.0001$), NO₂⁻ (11.8 \pm 7.3 vs 4.8 \pm 5.3 μ M, $p<0.0001$), NO₃⁻ (50.4 \pm 39.3 vs 20.9 \pm 16.7 μ M, $p<0.0001$) and P-Selectin (120.8 \pm 56.7 vs 93.0 \pm 26.1 ng/mL, $p=0.02$). Post ASA inhibition of 11dhTxB2 was 71.5% (3,665 to 996) in DM and 75.1% (2,450 to 624) in controls, but DM had twice as many ASA non-11dhTxB2 responders (>1,500) than controls (14.8% and 8.4%). Post-ASA 11dhTxB2 levels in DM (996 \pm 845) were significantly higher than controls (624 \pm 509, $p<0.0001$). ASA had no effect on 8-isoPGF2 α , NO₂⁻, NO₃⁻, P-Selectin, anti-HDL antibodies or PON1 activity in DM or controls.

Conclusion: ASA had no significant effect on oxidative stress, HDL-associated antioxidant PON1 activity, nitric oxide metabolites or P-Selectin in either DM or controls. The degree of 11dhTxB2 inhibition was similar in DM and controls though ASA non-responders were more frequent in DM despite greater baseline 11dhTxB2 concentration.

758

The role of oxidative stress and inflammation on cellular senescence in diabetesS. Del Guerra¹, M. Gabriele¹, R. Lupi², F. Pancani¹, R. Pandolfi¹, S. Del Prato¹;

¹Endocrinology and Metabolism, Metabolic Unit, ²Endocrinology and Kidney, Metabolic Unit, Azienda Ospedaliero-Universitaria Pisana, Pisa, Italy.

Background and aims: A growing number of observations suggest that telomere shortening is associated with the spectrum of alterations of glucose metabolism. Telomere shortening characterizes both type 1 and type 2 diabetes, but initial telomere shortening has been reported in subjects with glucose intolerance as well. However, it is still unclear to which extent acceleration of telomere attrition and subsequent shortening is the consequence of hyperglycemia. In this study we have evaluated whether oxidative stress and chronic inflammation observed in diabetic patients can be associated with telomere length and telomerase activity.

Materials and methods: We recruited 28 non-diabetic subjects (ND: 49 \pm 10 yrs old; 16M/12F; BMI 24.6 \pm 3.3 Kg/m²), 19 type 1 diabetes (T1DM: 47 \pm 11 yrs; 8M/11F; BMI 25.5 \pm 2.2 Kg/m², Diabetes duration 26.6 \pm 10.3 yrs, HbA1c 8.4 \pm 0.3%) and 19 type 2 diabetes (T2DM age, 54 \pm 9 yrs; gender, 10M/9F; BMI 26.7 \pm 1.8 Kg/m², Diabetes duration 14.2 \pm 9.4 yrs, HbA1c 7.4 \pm 0.3%) patients. In all patients anthropometric data were collected and blood was drawn for lab tests and determination of nitrotyrosine (a marker of oxidative stress) concentration. Genomic DNA and total RNA were extracted from circulating nucleated blood cells. Telomere length was determined by Real-Time qPCR, while Real-Time RT-PCR was used for assessment of telomerase subunits

HTERT (catalytic component) and HTERC (RNA component), and CCR2 gene expression.

Results: As compared to ND (0.153 ± 0.025), telomere length was significantly reduced in T2DM (0.043 ± 0.011 ; $p < 0.001$) but not in T1DM (0.189 ± 0.077). On the contrary, the expression of HTERT ($+319 \pm 25\%$) but not HTERC subunits ($126 \pm 4\%$) was higher ($p < 0.05$) in T1DM than T2DM ($122 \pm 13\%$ and $147 \pm 5\%$, respectively). HTERT mRNA expression was higher in diabetics than in controls respect to ND (all $p < 0.05$ or less). After normalization by telomerase activity, a significant reduction in telomere length became apparent in T1DM (51.35 ± 4.7) and, to a greater extent, in T2DM (8.08 ± 1.45) as compared to ND (248.9 ± 44.6 ; all $p < 0.01$). In T1DM, but not in T2DM, the female gender was associated with a shorter telomere length. Telomere length was negatively associated with age in ND, while in T2DM was negatively related to age, total and LDL cholesterol and positively correlated with HDL-cholesterol. In T1DM it was inversely correlated with total while the relationship was positive with HDL-cholesterol concentration. CCR2 mRNA expression was higher in both T1DM ($+256.2 \pm 14.9\%$) and T2DM ($+656.9 \pm 58.4\%$) as compared to ND (all $p < 0.001$). In the study population as a whole, CCR2 mRNA expression was inversely correlated with telomere length ($r = 0.515$, $p = 0.039$) and positively correlated with HTERT ($r = 0.849$, $p < 0.001$) and HTERC ($r = 0.686$, $p = 0.019$). Similarly, nitrotyrosine levels were greater in diabetics (T2DM: 0.76 ± 0.09 OD, T1DM: 0.52 ± 0.07 OD), than in ND (0.31 ± 0.02 OD, all $p < 0.05$ or less). Moreover, a positive correlation was found between nitrotyrosine levels and CCR2 mRNA expression ($r = 0.513$, $p = 0.041$) and a negative one with telomere length ($r = 0.330$, $p = 0.038$) and C-peptide concentrations ($r = 0.281$, $p = 0.023$).

Conclusions: Our results confirm a link between telomere length, impaired telomerase activity and diabetes. We suggest that oxidative stress and inflammatory status can contribute to shortening of telomere in diabetic individuals.

759

Regulation of the G6pc promoter activity by glucotoxicity: identification of a new mechanism involving ROS and the HIF-1 α transcriptional activity

A. Gautier-Stein, M. Soty, C. Zitoun, J. Chilloux, F. Rajas, G. Mithieux; Inserm 855, Lyon, France.

Background and aims: The activation of Glucose-6-phosphatase, which is the key enzyme of endogenous glucose production (EGP), is associated to type 2 diabetes. The expression of its catalytic unit (G6PC) is paradoxically increased by high glucose levels. This increase might thus contribute to unrestrained EGP characterizing this pathology. Glucotoxicity of type 2 diabetes is linked to the production of reactive oxygen species (ROS). ROS can induce gene expression by the induction of O-linked N-acetyl-glucosaminylation of transcription factors. ROS might also control gene expression through the regulation of the hypoxia inducible factor 1 (HIF-1). HIF-1 is composed of the HIF-1 α and HIF-1 β subunits. However, HIF-1 α only is regulated by hypoxia. In normoxia, the hydroxylation of HIF-1 α first induces its degradation and second inhibits its interaction with the cofactor CREB binding protein (CBP). Hydroxylation of HIF-1 α is inhibited by low O_2 levels or different stimuli such as ROS. In this work, we made the hypothesis that ROS induced by high glucose levels might control the transcription of G6pc through HIF-1 α .

Materials and methods: We analyzed the mechanism of the transcriptional control of G6pc by glucose in the hepatoma cell line HepG2. Cells were treated for 24 hrs with 5 or 25 mM glucose. ROS levels were decreased by the addition of an antioxidant (5.10^{-4} mol/L Trolox). Luciferase assays and chromatin immunoprecipitation were used to decipher molecular mechanisms. We confirmed the existence of the mechanisms evidenced in HepG2 cells in primary rat hepatocytes and in primary hepatocytes of a model of diet induced obesity (mice fed on a high fat-high sucrose diet).

Results: In HepG2 cells, glucose increased G6pc promoter activity in parallel to ROS levels. The addition of antioxidant prevented both the induction of G6pc promoter activity and the increase of ROS levels. The induction of G6pc promoter activity by glucose was prevented by a HIF-1 α dominant negative or a RNAi targeting CBP. In primary hepatocytes, we confirmed that decreasing the amount of ROS by antioxidant decreased the induction of G6pc mRNA levels by glucose. Glucose induced the stabilization of HIF-1 α protein and its binding to the G6pc promoter. Moreover, glucose increased the association of HIF-1 α with CBP and the binding of CBP to the G6pc promoter. The binding of CBP induced by glucose was prevented in the presence of antioxidant. Finally, we showed that levels of HIF-1 α protein and its binding to the G6pc promoter increased in the liver of mice fed on a high fat-high sucrose diet.

Conclusion: In this study, we identify a new mechanism of gene regulation by glucose. We show that glucose induces the expression of G6pc by a mechanism depending on ROS. We propose that ROS controls the transcriptional activity of HIF-1 α as does hypoxia. ROS first induce the stabilization of HIF-1 α and then allow the interaction of HIF-1 α with CBP. This mechanism may contribute to the increase of EGP during type 2 diabetes.

The endothelial nitric oxide synthase (eNOS) co-factor tetrahydrobiopterin (BH4) suppresses hepatic gluconeogenesis and lowers blood glucose levels

A. Abudukadier, Y. Fujita, A. Obara, M. Hosokawa, S. Fujimoto, T. Fukushima, Y. Sato, M. Ogura, Y. Nakamura, N. Inagaki; Department of Diabetes and Clinical Nutrition, Kyoto University, Japan.

Background and aims: The tetrahydrobiopterin (BH4), an essential cofactor for endothelial nitric oxide synthase (eNOS), is crucial for the synthesis of nitric oxide by eNOS. In our previous report, we demonstrated that intra-hepatocellular eNOS is required for activation of AMP-activated protein kinase (AMPK) and suppression of hepatic gluconeogenesis by metformin in liver. Those findings suggest that nitric oxide produced by eNOS plays an important role in hepatic glucose metabolism. The aim of the present study was to determine whether BH4 suppresses gluconeogenesis and increases AMPK activation in hepatocytes.

Materials and methods: Hepatocytes were isolated from male 8-week-old C57/BL6 mice by collagenase digestion. Primary hepatocytes were maintained in DMEM with 10% fetal bovine serum. Protein expressions of AMPK α and phospho-AMPK α were analyzed by Western blot. For gluconeogenesis measurements, hepatocytes were isolated after overnight fast and incubated for 60 minutes in glucose-free KRB buffer with 1 mmol/l pyruvate plus 10 mmol/l lactate. Glucose production was determined by glucose oxidase method. In addition, eNOS-deficient mice were used to confirm the requirement for intra-hepatocellular nitric oxide production for the effect of BH4 in suppression of hepatic gluconeogenesis. To determine whether BH4 lowers blood glucose levels *in vivo*, 20 mg/kg BH4 was injected intraperitoneally to streptozotocin induced diabetic wild-type and eNOS-deficient mice and to AKITA mice fasted for 16 hours. To assess hepatic gluconeogenesis *in vivo*, pyruvate tolerance tests were performed in wild-type and eNOS-deficient mice.

Results: One-hour exposure of 50 μ mol/l BH4 significantly suppressed hepatic gluconeogenesis (BH4, 72 ± 17 ; control, 101 ± 12 nmol/mg protein; $p < 0.001$) and activated AMPK in wild type mouse hepatocytes. These effects of BH4 did not appear in eNOS-deficient mouse hepatocytes. Sepiapterin, a BH4 precursor, also suppressed hepatic gluconeogenesis significantly and activated AMPK. Sepiapterin had no effect on hepatic gluconeogenesis or AMPK activation in eNOS-deficient mouse hepatocytes. Sodium nitroprusside, a nitric oxide donor, suppressed hepatic gluconeogenesis significantly and activated AMPK in both wild-type and eNOS-deficient mouse hepatocytes. Administration of 20 mg/kg BH4 lowered blood glucose levels significantly in diabetic wild-type mice and AKITA mice ($p < 0.05$), but not in diabetic eNOS-deficient mice. In pyruvate tolerance test, 20 mg/kg BH4 injected intraperitoneally to wild-type mice decreased significantly elevation of blood glucose levels compared with saline injection. However, in eNOS-deficient mice, no effects of BH4 were detected.

Conclusion: BH4 suppresses hepatic gluconeogenesis and activates AMPK and lowers blood glucose levels eNOS-dependently. Supplementation of BH4 or its precursor might represent a novel therapeutic approach in type 2 diabetes through improvement of hepatic glucose metabolism.

761

iNOS modulates the NF κ B signalling pathway through a NO-dependent pathway in models of inflammation induced insulin resistance

K. Bellmann, A. Charbonneau, A. Marette; Department of Medicine, Faculty of Medicine, Cardiology Axis of the Quebec Heart and Lung Institute, Laval University, Canada.

Background and aims: It has been previously demonstrated that nitric oxide (NO) and various reactive nitrogen species modulate the NF κ B signaling pathway in cancer development and apoptosis. However, until now, no studies have tested whether iNOS activation modulates the NF κ B signaling pathway in metabolic tissues in conditions of insulin resistance. We have previously shown that

hepatic iNOS plays an important role in lipid- and endotoxin-induced insulin resistance and that this was mediated by an iNOS-dependent tyrosine nitration of insulin signaling proteins including Akt. Here, we evaluated whether iNOS can modulate NFκB activation through a NO-dependent mechanism.

Materials and methods: We subjected 8–12 weeks old WT and iNOS-KO mice to an acute injection of either saline (SAL) or LPS (20 mg/kg, i.p.) to assess insulin sensitivity during a hyperinsulinemic-euglycemic clamp protocol. Furthermore, we induced iNOS in a rat hepatic cell line (Fao) using a cytokine mixture (TNFα, IFNγ, IL-1β) in the presence or absence of the iNOS inhibitor 1400W to block inflammatory NO production.

Results: During euglycemic-hyperinsulinemic clamps we observed a strong reduction of the glucose infusion rate after treatment with LPS, which was completely inhibited in mice lacking iNOS. This was associated with improved insulin-mediated suppression of hepatic glucose production in iNOS-KO mice and increased Akt activation. Furthermore, a significant increase of IKKβ phosphorylation and tyrosine nitration of IκBα was observed in the livers of LPS-treated WT mice indicating an increase in NFκB activity. These effects of LPS were blunted in livers of iNOS-KO mice, suggesting a possible feedforward mechanism of NFκB activation by iNOS in this metabolic tissue. In agreement with the in vivo data, IKK phosphorylation and NFκB transcriptional activity were increased in Fao hepatic cells treated with cytokines, but this was reduced by inhibition of iNOS activity using the selective iNOS inhibitor 1400W.

Conclusion: We conclude that iNOS may positively activate the NFκB pathway through a feedforward mechanism and thus contribute to exacerbate inflammation and thereby further impairing insulin signaling and hepatic insulin action in inflammatory settings.

Effect of dietary macronutrients on oxidative stress, cardiovascular risk factors, and insulin sensitivity in obese, non-diabetic, premenopausal women

A.E. Kitabchi¹, F.B. Stentz¹, K. McDaniel², J. Wan², F. Tylavsky², E. Nyenwe¹, C. Sands²

¹Endocrinology, Diabetes and Metabolism, University of Tennessee Health Science Center, ²University of Tennessee Health Science Center, Memphis, USA.

Background and aims: Various dietary interventions are known to result in significant weight loss and reduction in cardiovascular risk factors (CVR), but advantages of these diets are not established. We hypothesized that high-carbohydrate (CHO) diet (HC) (55% CHO, 30% fat, 15% protein) results in greater triglycerides (TG), oxidative stress (DCF), and lipid peroxidation (MDA) than high-protein (HP) diet (30% protein, 30% fat, and 40% CHO).

Material and methods: The diets based on resting energy expenditures with 500 Kcal reductions were provided by pre-packaged food on a weekly basis. To date, 13 (8HP, 5HC) non-diabetic, obese, pre-menopausal women were studied in a randomized prospective protocol. DCF, MDA, adiponectin and E-selectin were analyzed by ELIZA and colorimetric microplate assays. HOMA-IR was determined by the homeostasis model assessment of insulin resistance. CVR consisted of BP, BMI, and TG.

Results: The data depict results at baseline and after 6 months of diet.

Parameters measured	HP Baseline P* 6 months	HC Baseline P* 6 months	p**
BMI (kg/m ²)	42 ± 7.0 0.01 38.8 ± 7.3	37.5 ± 0.02 35.3 ± 5.4	0.28
% weight loss	0.01 8.6 ± 1.7	0.01 7.2 ± 1.9	0.60
BP (sys/diast)	129/83 ± 4/3 0.01 119/74 ± 3/3	128/82 ± 3/3 0.01 120/75 ± 3/3	0.70
TG (mg/dl)	102 ± 14 0.01 85 ± 10	102 ± 13 0.02 94 ± 9	0.02
DCF (μM)	3.2 ± 0.2 0.01 2.4 ± 0.1	3.2 ± 0.2 0.04 2.9 ± 0.1	0.02

The relationship between coronary atherosclerosis, functional exercise capacity and activin A in patients with type 2 diabetes

O. Johansen¹, P. Aukrust², K. Endresen³, S. Aakhus³, E. Orvik¹, C. Smith², K.I. Birkeland⁴, L. Gullestad³, T. Ueland²

¹Medical department, Asker and Baerum Hospital, ²Research Institute for Internal Medicine, ³Department of Cardiology, ⁴Department of Endocrinology, Oslo University Hospital, Norway.

Background and aims: Despite intensified control of risk factors, silent coronary artery disease (CAD) is still a frequent complication of type 2 diabetes (T2D) and associated with cardiac events. Therefore, new, validated biomarkers are needed to identify patients with silent CAD to reduce the need for invasive testing. Activin A, a multifunctional cytokine member of the TGF-β superfamily, plays a role in inflammation, atherogenesis and glucose homeostasis. We hypothesized that activin A is related to the extent of coronary artery disease in T2D and may be used as a marker for silent CAD.

Materials and methods: The present study is a substudy of the Asker and Baerum Cardiovascular Diabetes (ABCD) study and comprised 133 patients (pts) aged 18–75 years with T2D for a cross-sectional investigation of the prevalence of CAD. Participants underwent clinical examination, stress electrocardiogram and ergospirometry with gas exchange, in addition to blood and urine sampling. Pts with ≥1 CV risk factor were voluntarily referred to invasive coronary angiography and echocardiography. Between-group comparisons were conducted with t-, Mann-Whitney U- or chi squared test.

Results: Serum samples of activin A were available from 102 pts (mean ± SD age: 59 ± 10 y, 28% female, BMI 30.3 ± 5.5 kg/m², diabetes duration 6.7 ± 6.7 years) where 87 were free from previous CAD. The mean activin A level was 0.71 ± 1.16 ng/ml with min and max values of 0.04 and 11.79 ng/ml. Activin A in the 73 pts with T2D with coronary angiography tended to be higher in pts with CAD (> 50% luminal stenosis of major arteries, n=19) versus those without (n=54), i.e., 0.72 ± 0.37 vs 0.58 ± 0.36 ng/ml, p=0.16. The median value of activin A (0.56 ng/ml) for the overall T2D group (n=102) was set as cut-off to explore the association of activin A to anatomical indices of CAD, functional parameters and CV risk factors (table). Pts were comparable for history of smoking, hypertension, CRP and lipid levels, but those with activin A > median were older (61 ± 11 vs 56 ± 9 y, p=0.016) and had lower eGFR (96 ± 19 vs 84 ± 16 ml/min · 1.73 m² [p<0.01]), reduced exercise capacity and had significantly more CAD (table).

Conclusion: These observations imply that, in T2D, activin A may be a useful surrogate marker to define CV risk, and may facilitate early identification of patients with subclinical CAD. We speculate that the increased levels of activin A may reflect the underlying chronic pathological processes.

Pts characteristics and angiographic and exercise parameters according to level of Activin A

	Activin A ≤ 0.56 ng/mL	Activin A > 0.56 ng/mL	p-value
CRP (mg/l)	1.5 (0.9,3.0)	1.8 (1.2,2.9)	0.431
HbA1c (%)	7.4 (6.3,8.0)	7.1 (6.5,8.2)	0.755
UKPDS score (%)	14.5 ± 8.4	20.8 ± 12.5	0.005
MVO2 (O ₂ /kg/min)	25.4 ± 6.4	21.4 ± 5.8	0.004
[n=82]			
Measured MET	7.2 ± 1.8	6.5 ± 1.7	0.053
[n=82]			
Left ventricular ejection fraction (%)	64.2 ± 6.7	63.1 ± 8.3	0.552
[n=72]			
Coronary angiography: Stenosis > 50% (n=73)	6 (17%)	13 (35%)	0.062
Coronary angiography: ≥ 2 vessel disease (n=73)	1 (3%)	10 (27%)	0.004
Coronary angiography: Extent score (n=73)	0.64 ± 1.05	1.51 ± 2.04	0.024

Clinical and metabolic risk factor association with c-reactive protein (hCRP) in type 2 diabetic subjects: base line finding from BNDC trial
 M.M. Iqbal¹, Z. Ahmed², M.A. Mansur², S. Iqbal², N. Nahar², S. Choudhury², S. Ali², A.K.M. Alam², A.K. Azad Khan²;
¹Nephrology, NIKDU & BIRDEM, ²BIRDEM, Dhaka, Bangladesh.

Background and aims: The development and progression of diabetes and its complications are greatly affected by inflammatory mechanisms. The aim of this study was to investigate the association of inflammatory marker high sensitive CRP (hCRP) with a number of clinical and laboratory parameters monitored during regular follow-up of a diabetic patient.

Materials and methods: Here base line data from an ongoing trial on controlling blood pressure, nephropathy and dyslipidemia in type 2 diabetics is primarily analyzed. In this study both diabetic nephropathy (DN) and those without (DM) were included. Association of hCRP at different cut-off values with blood pressure (BP), urinary protein (UTP), serum creatinine (SCr) HbA1c, lipids (LDL) and serum albumin (Alb) was observed.

Results: Total 730 subjects were included. Serum hCRP level was elevated (>3mg/l) in 55% subjects. Association study showed hCRP had no relation with bmi, systolic & diastolic BP, UTP or SCr but a positive correlation with HbA1c ($p<0.01$) and negative with Alb ($p<0.01$). An HbA1c above and below 7% was seen in 59 vs. 41% of all subjects with hCRP of 4.2 ± 4.9 vs. 5.2 ± 6.1 , mg/l, ($p<0.03$); LDL above and below 100mg/dl was seen in 48 vs. 52% with hCRP of 4.1 ± 4.5 vs. 5.3 ± 6.8 , mg/l, ($p<0.01$) and serum albumin above and below 4.0 g/dl cut-off in 60 vs. 40% subjects with the hCRP of 4.5 ± 5.1 vs. 5.6 ± 6.5 , mg/l, ($p<0.001$). The CRP levels didn't vary significantly for bmi above and below 25kg/m^2 and BP>140/90 mmHg. In sub grouping 70% ($n=513$) belonged to DN and 30% ($n=217$) DM group. The percentage of DN vs. DM subjects for hCRP cut-offs at <3 mg/l (39 vs. 62 %), 3-10 mg/l (50 vs. 30%) and >10 mg/l (12 vs. 8 %), ($p<0.001$) respectively showed higher values were present in both groups with more in nephropathy. In DN group comparisons according to same 3 hCRP cut-offs showed similar Systolic BP ($137\pm21, 138\pm21$ and 132 ± 19 , mmHg, $p=NS$), diastolic BP ($78\pm10, 79\pm9$ and 78 ± 9 , mmHg, $p=NS$) and also in DM group Systolic BP ($119\pm13, 120\pm12$ and 118 ± 18 , mmHg, $p=NS$) and diastolic BP ($75\pm8, 77\pm7$ and 72 ± 8 , mmHg, $p=NS$) were unchanged indicating no association of CRP with blood pressure. Similarly for different levels of CRP the UTP levels in DN subjects didn't vary ($1.8\pm2.0, 1.8\pm1.7$ and 1.8 ± 1.9 , g/day; $p=NS$).

Conclusion: It may be concluded that serum CRP level is elevated in majority of diabetic subjects and this has no apparent influence on levels of blood pressure or proteinuria. It seems that raised CRP is more linked to poor diabetes control with dyslipidemia and hypoalbuminemia indicating a higher prevalence of malnutrition-inflammation- atherosclerosis syndrome.

Effects of glucose on insulin stimulated cell proliferation

A. Lundby, A. Lützen, T. Glendorf, B.F. Hansen;
 Insulin Biology, Novo Nordisk A/S, Maaloev, Denmark.

Background and aims: It is well established that type 2 diabetic patients have a higher risk of certain cancers. However, the underlying mechanisms are not clear and both hyperglycemia and hyperinsulinemia have been proposed as possible links. The latter has been suggested to be the more important factor due to epidemiological findings and the fact that certain cancer cells have a constitutively high level of glucose uptake and are able to fully satisfy their glucose requirements at normoglycemia. However, the different glucose transporters (GLUTs) have different Km values. Thus depending on the GLUT expression pattern, glucose concentration could have an impact on glucose uptake and cellular proliferation. We examined the insulin-stimulated proliferative response in the presence of low (5 mM) and high (25-33 mM) glucose levels in a panel of different cell lines.

Materials and methods: L6 rat myoblasts overexpressing IR-A (L6-hIR), human breast (MCF7) or colon (COLO205) adenocarcinoma cells, and rat hepatoma cells (H4IIE). Receptor expression patterns were evaluated by FACS, Western blot or ELISA with monoclonal antibodies against the IR or IGF-IR. Cell proliferation was measured as incorporation of radioactively labeled thymidine using either traditional filter plates or cytostar-TTM scintillation microtiter plates.

Results: Three out of four cell lines showed a robust insulin-stimulated mitogenic response. The most pronounced response was seen in L6-hIR cells, where thymidine incorporation was increased more than 15-fold (EC_{50} of 1.5 nM). MCF7 and COLO205 cells also responded to insulin (3-4-fold) with EC_{50} values in the low nanomolar range. The H4IIE cells responded weakly to insulin (<2-fold) and only at high insulin levels. When the insulin dose-response effects were studied in either low or high glucose concentrations, no effect of high glucose was found in L6-hIR or MCF7 cells. If anything, a small inhibitory effect at 25 mM glucose was seen for MCF7 cells. In contrast, high glucose levels strongly promoted insulin-mediated thymidine incorporation in colon (COLO205) and liver (H4IIE) cancer cells. In COLO205 cells, a shift in the dose-response curve was observed. Thus, more than a doubling in DNA synthesis was seen at 100 pM insulin, but no effect was observed at maximal insulin concentration. Also in the absence of insulin there was an increased (1.6-fold) thymidine incorporation in response to high glucose. This insulin-independent effect was even higher in H4IIE cells showing a 3-4-fold increase in thymidine incorporation in response to high glucose.

Conclusion: We have found a significant difference in the proliferative response to glucose across a panel of cell lines. The growth of H4IIE (liver) and COLO205 (colon) cancer cells appears to be sensitive to glucose levels, whereas MCF7 (breast) cancer cells and myoblasts overexpressing the IR are unresponsive to glucose. Interestingly, liver and colon cancers are among the more frequently seen in patients with type 2 diabetes. Thus, control of blood glucose levels could be important for prevention of some cancer forms.

	IR	IGFIR	IR:IGF-IR ratio	Effect of insulin	Effect of glucose
L6-hIR	204.000	90.000	2:1	+++	no effect
MCF7	4.000	37.000	1:9	++	no effect
COLO205	2.100	13.900	1:7	++	++
H4IIE			1:6	(+)	+++

Insulin glargine does not exhibit carcinogenicity in rodents: review of safety studies

I. Stammberger;
 sanofi-aventis, Frankfurt, Germany.

Background and aims: Insulin glargine (GLA) was tested in life-time carcinogenicity studies in rats and mice, targeting the incidence of spontaneously

occurring tumors and development of rare tumors. The 1995–1997 studies were reassessed for their validity with regard to design, survival rates and incidence of neoplastic mammary lesions in female animals.

Materials and methods: In both 2-year studies 50 animals per sex and per group were used. Three dose levels of GLA were used (2, 5, and 12.5 IU/kg) along with saline control (SC), vehicle control (VC) and NPH insulin (NPH; 12.5 IU/kg in mice or 5 IU/kg in rats) groups. Animals were palpated for nodules monthly until 6 months of age and then every 2 weeks to study end. Rats found dead were autopsied the same day. Statistical analyses were performed for each type of mammary tumor using a modified Peto lifetime adjusted analysis and the Bieler-Williams poly-3-test.

Results: Survival rates by weeks 80 and 90 in female mice were 50 and 30% (2 IU/kg GLA), 62 and 42% (5 IU/kg GLA), 72 and 54% (12.5 IU/kg GLA), 64 and 32% (SC), 52 and 34% (VC) and 56 and 42% (NPH), respectively. In female rats, they were 72 and 56% (2 IU/kg GLA), 74 and 60% (5 IU/kg GLA), 60 and 36% (12.5 IU/kg GLA), 70 and 60% (SC), 74 and 60% (VC) and 72 and 66% (NPH), respectively. Mammary tumors in mice were adenocarcinoma. Incidence was 0 (2 IU/kg GLA), 0 (5 IU/kg GLA) and 2 (12.5 IU/kg GLA) vs. 2 (SC), 0 (VC) and 2 (NPH). Mammary tumors in rats were mainly fibroadenoma and adenocarcinoma. Incidence of fibroadenoma was 26 (2 IU/kg GLA), 22 (5 IU/kg GLA) and 15 (12.5 IU/kg GLA) vs. 26 (SC), 21 (VC) and 28 (NPH). Incidence of adenocarcinoma was 7 (2 IU/kg GLA), 8 (5 IU/kg GLA) and 7 (12.5 IU/kg GLA) vs. 9 (SC), 9 (VC) and 7 (NPH). Statistical analysis revealed no significant differences between GLA and controls, including NPH insulin, in either mice or rats.

Conclusion: Both studies met current design practices and fulfilled the current FDA requirements that enough animals lived long enough to provide adequate exposure to GLA and to be at risk of forming late-developing tumors. The negative carcinogenicity studies confirm the long-term safety of insulin glargine, as derived from 2-year rodent studies.

Metformin monotherapy or its combination with other antidiabetic drugs reduces cancer risk in type 2 diabetes subjects

S. Rizza¹, P. Sarnelli¹, M. Copetti², D. Lauro¹, R. Lauro¹, M. Federici¹;

¹Tor Vergata University, Rome, ²IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.

Background and aims: *In vitro* studies show that metformin reduces cellular proliferation, colonies formation and arrests growth of breast, colon, and prostate cancer cell lines, regardless its metabolic effect through the activation of AMPK-kinase. In humans metformin is associated to a reduction of cancer risk if compared to other antidiabetic medicines. Nevertheless, few evidences are available about the effect on cancer risk when metformin is associated to other antidiabetic drugs, and these results are controversial. The aim of our study is to evaluate the cancer risk in subjects with type 2 diabetes (DM2) in relation to hypoglycaemic treatment. Study hypothesis is that metformin, even in association to other hypoglycaemic therapies, reduces cancer risk compared to therapeutic regimens that do not include metformin.

Materials and methods: This is a retrospective study concerning an ambulatory cohort of patients followed up for DM2 (n=427).

Results: DM2 subjects showed a higher crude prevalence of cancer compared to a control population (426 non-diabetic hypertensive subjects) (12.6% vs 18.5%, p=0.02). Adjusted for age, sex, BMI and smoking habit, the risk of cancer diagnosis remained higher in DM2 individuals respect to non-diabetic controls (OR 1.77, 95% CI: 1.18 to 2.36). The incidence of cancer diagnosis among diabetic subjects was higher (29.3%) among individuals who never took metformin compared to subjects that have taken only metformin (10.0%), but also in comparison with those who received metformin in combination with other hypoglycaemic agents (18.3%). This difference remained unchanged even after adjustment for confounding covariates such as age, sex, smoking and BMI. Thus, the new diagnosis of cancer is statistically higher in patients who have never taken metformin. In particular, this group has an almost threefold risk of a diagnosis of cancer (HR: 2.93, 95% CI: 1.43 to 6.01) than metformin monotherapy group and than subjects treated with metformin in association with other hypoglycaemic agents. This risk is independent from age, sex, smoking and BMI.

Conclusion: Type 2 diabetes is associated with an increased risk of developing cancer respect to non-diabetics by 77%. In DM2 individuals metformin can reduce the risk of cancer regardless of associated hypoglycaemic treatment.

768

Metformin inhibits IGF1 induced proliferation and signalling in a Caveolin-1 dependent manner in NSCLC cells

B. Salani¹, S. Maffioli¹, A. Parodi², M. Hamoudane¹, M. Passalacqua³, S. Ravera⁴, R. Cordera¹, D. Maggi¹;

¹Department of Endocrinology and Medicine (DiSEM), ²Centre of Excellence of Biomedical Research (CEBR), ³Department of Experimental Medicine (DIMES), ⁴Department of Biology (DiBio), University of Genova, Italy.

Background and aims: The biguanide Metformin has potential antineoplastic activity. Metformin regulates cellular growth in cancer cells acting through cellular energy sensors with increase AMP/ATP ratio and activation of AMPK. We examined whether Metformin inhibits IGF1 induced proliferation and transduction pathway in Non Small Cell Lung Cancer (NSCLC) cell lines. Since Caveolin-1 expression plays a role in the cellular response to growth factor, we examined the effect of Metformin in Calu-1 and Calu-6: two NSCLC cell lines that respectively express high and low amount of Caveolin-1 (an essential component of caveolae).

Materials and methods: Biochemical analysis in Calu-1 and Calu-6 following Metformin and IGF1 treatment was performed by Western Blot. To modulate Cav-1 expression, Calu-1 and Calu-6 cells were transiently transfected respectively with a Cav-1 siRNA or Ctr siRNA and a pEGFPN1-plasmid expressing wt-Cav-1 or the empty vector. AMP/ATP ratio was measured by enzymatic assay.

Results: We observed that Calu-6 cells did not respond to acute Metformin inhibitory effect on IGF-IR induced cell growth and signalling, while Calu-1 cells were sensitive. Metformin inhibited IGF-I-induced proliferation of NSCLC in Calu-1 and resulted in a decrease phosphorylation of Akt and FOXO3a, a downstream target of Akt. Phosphorylation of FOXO3a by Akt induces its cytoplasmic sequestration and a reduced Akt signalling causes relocation of FOXO3a to the nucleus. In the presence of IGF1, Metformin retained Foxo3a into the nucleus in Calu-1 but not in Calu-6. We found that modulation of Cav-1 expression influenced Metformin action affecting AMPK phosphorylation as well as AMP/ATP ratio induced by Metformin. Silencing of Cav-1 in Calu-1 cells inhibited AMPK phosphorylation and AMP/ATP ratio increase induced by Metformin while Cav-1 expression in Calu-6 improved AMPK phosphorylation and AMP/ATP ratio increase in presence of Metformin.

Conclusion: Altogether, these data demonstrate that Metformin by AMPK phosphorylation and change of energy balance could inhibit IGF-IR signalling and raise the possibility of future utilization of AMPK activators in the treatment of NSCLC.

769

Metformin inhibits insulin activation of the AKT and mTOR pathways and cellular proliferation in primary endometrial epithelial cells

D.J. Selen¹, C.A. Flannery², H.S. Taylor¹;

¹Reproductive Endocrinology, ²Endocrinology, Internal Medicine, Yale School of Medicine, New Haven, USA.

Background and aims: Obesity and type 2 diabetes are independent risk factors for the development of endometrial hyperplasia and carcinoma. Hyperinsulinemia is a hallmark of obesity and type 2 diabetes, and may play a role in endometrial cell proliferation. In several case reports, metformin has reversed progesterin-resistant endometrial hyperplasia. We sought to determine the effect of insulin on signaling pathways associated with hyperplasia in primary endometrial epithelial cells.

Materials and methods: Epithelial cells were separated from the endometrial tissues of ten women, and cultured in low glucose DMEM. Western blot analysis of phosphorylated and total AKT, 4E-BP1, and p70S6K was done after acute insulin stimulation in a dose range of 0.1 to 100nM for each group of epithelial cells. We then examined the relative concentrations of the same signaling proteins in cells pre-treated with 1 to 10mM of metformin, with and without insulin.

Results: Primary epithelial cells demonstrated a four fold increase (p=0.02) in cell proliferation over 24 hours in the presence of insulin relative to vehicle. Treatment with metformin abolished the proliferative effect of insulin. Insulin induced a robust dose-dependent phosphorylation of AKT and weak to robust activation of mTOR signaling in all ten primary epithelial cell cultures. This activation was inhibited by wortmannin, a PI3 kinase inhibitor. Metformin treatment of epithelial cells for 24hrs reduced the insulin-induced

phosphorylation of AKT, p70S6K, and 4E-BP1 at physiological doses of insulin (0.1–0.5nM). However, metformin did not alter insulin-induced AKT or mTOR pathway activation at supraphysiological doses of insulin (10–100nM). **Conclusion:** We have demonstrated that primary endometrial epithelial cells are sensitive to insulin, and that insulin likely promotes cell proliferation through activation of the AKT and mTOR pathways. Our data also provides preliminary evidence that metformin may have a direct effect on the endometrium, resulting in a reduced effect of insulin on cell proliferation and activation of signaling pathways. Metformin may be beneficial in the treatment of endometrial hyperplasia for women with hyperinsulinemia, in the setting of obesity and type 2 diabetes.

Dipeptidyl peptidase-4 inhibitors and risk of cancer: myth or reality?

M. Monami¹, I. Dicembrini², S. Zannoni¹, C. Lamanna³, E. Mannucci³;

¹Cardiovascular Medicine - University of Florence, Section of Geriatric Cardiology and Medicine, ²Careggi Teaching Hospital, Obesity Agency,

³Careggi Teaching Hospital, Diabetes Agency, Florence, Italy.

Background and aims: Dipeptidyl peptidase-4 inhibitors (DPP4i) have been recently associated with increased risk of cancer and pancreatitis. Aim of the present meta-analysis of randomized clinical trials is the assessment of the effect of DPP4i on the incidence of cancer, and pancreatitis.

Materials and methods: A meta-analysis was performed including all randomized clinical trials with a duration of at least 24 weeks, enrolling patients with type 2 diabetes, comparing DPP4i with either placebo or active drugs.

Results: Fifty-three trials enrolling 20,312 and 13,569 patients for DPP4i and comparators, respectively, were included, reporting 176 malignancies and 22 pancreatitis. DPP4i, compared with placebo or other treatment, were associated with a similar risk of cancer (MH-OR 1.020[0.742–1.402]; $p=0.90$) and pancreatitis (0.786[0.357; 1.734], $p=0.55$).

Conclusion: The present meta-analysis seems to exclude any relevant short term effect of DPP4i on the incidence of cancer or pancreatitis.

Effect of different anatomical changes in gastrointestinal anatomy on glycaemic control after surgery in type 2 diabetic patients with early gastric cancer

T. Kurose, T. Hyo, K. Watanabe, S. Fujiwara, H. Kuwata, K. Sugizaki, Y. Kitamoto, D. Yabe, Y. Seino;

Division of Diabetes, Clinical Nutrition and Endocrinology, Department of Internal Medicine, Kansai Electric Power Hospital, Osaka, Japan.

Background and aims: There is a growing body of evidence that remission of diabetes without medications, could be after bariatric surgery for morbid obese diabetic patients. Normal insulin levels and euglycemia are often observed within several days after surgery, suggesting that weight loss alone cannot explain why this surgery improves diabetes. Whereas diabetes is traditionally viewed as a chronic, relentless disease in which delay of end-organ complications is the major treatment goal, GI surgery may offer a novel end point. The role for GI surgery in diabetes treatment, however, is not clearly defined. To investigate whether diabetes control is the result of GI tract surgery which preserve duodenum or not, we have evaluated the glycemic conditions in the patients with diabetes mellitus who were treated for early stage of gastric cancer by Roux-en-Y method (not preserve duodenum) or Billroth I method (preserve duodenum).

Materials and methods: Using ICD10 codes, we identified patients undergoing Roux-en-Y gastrojejunostomy (RY) or Billroth I (BI) reconstruction over 1 year. Fasting blood glucose, total cholesterol, serum albumin, percentage of lymphocyte in white cell count and body weight before and after surgery were tabulated and compared using student's t-test. Oral hypoglycemic agent and pharmacological therapeutics were evaluated for the follow up period.

Results: Between 2008 and 2010, we identified 16 patients with T2DM out of cohort of 85 who underwent either RY (8 of 16) or BI reconstruction (8 of 16) for early gastric cancer and survived more than 30 days after operation. Study participants are all Japanese and 15 male and 1 female (RY M/F=8/0, BI M/F=7/1). Mean age of RY was 69.8 ± 7.0 and BI was 68.6 ± 9.6 years, HbA1c of RY was 6.8 ± 1.0 and BI was 6.4 ± 0.6 %. Average fasting plasma glucose of RY was 124.1 ± 30.7 , whereas that of BI was 119.4 ± 16.4 mg/dl. After 1 year follow up in RY HbA1c was 6.0 ± 0.8 % ($p < 0.05$, vs the value 1 year before) and BI was 6.3 ± 0.5 (ns, vs the value 1 year before). Body weight of both groups reduced similar, and serum albumin, T-cholesterol, percentage of lymphocyte levels were not changed in both groups. There was also no change in diabetes medication in both groups before and after surgery.

Conclusion: In the RY group the diabetic control was improved after one year follow up, independent of changes in body weight and diabetes medication. The reconstruction method may affect the glycemic control in diabetic patients.

772

Mortality from common cancers among people with type 2 diabetes and the effect of socio-economic status

S.H. Wild, Scottish Diabetes Research Network Epidemiology Group; Centre for Population Health Sciences, University of Edinburgh, UK.

Background and aims: Type 2 diabetes (T2DM) is associated with increased incidence of several cancers, including those of the colon/rectum and breast and a protective effect against prostate cancer. Similar patterns for mortality from these common cancers might be expected although cardiovascular disease may act as a competing cause of death. The aims of this study were to describe absolute and relative mortality from common cancers (lung, colorectal, prostate and breast) among people with and without type 2 diabetes in the Scottish population and to investigate the effect of socio-economic status (SES).

Materials and methods: Data on people with diabetes were drawn from a population-based national diabetes register. Mortality rates for each cancer among men and women with T2DM who were aged 35–84 years in the period 2001–2007 were compared to corresponding rates for the non-diabetic Scottish population with direct age-standardisation using the European Standard Population. The non-diabetic population was created by subtracting numbers of deaths and person-years for people with type 1 or type 2 diabetes from the all-Scotland totals. SES was based on an area-based measure, the Scottish Index of Multiple Deprivation (SIMD), where Q1 and Q5

represent the most affluent and most deprived quintiles respectively. Poisson regression was used to estimate the relative risk (RR) of cancer mortality associated with T2DM compared to the non-diabetic population, adjusting for age or age and SES.

Results: Complete data were available for 210,994 people, representing 99.4% of those who had diabetes and were within the age range of interest for part or all of the study period. There were 2,081 deaths from lung cancer, 945 from colo-rectal cancer, 528 from breast cancer and 419 from prostate cancer. Age-adjusted mortality rates in both the T2DM cohort and general population, stratified by socio-economic status, are shown in the figure. Age adjusted RR (95% CI) for lung, colo-rectal and breast or prostate cancer were 0.94 (0.83 to 1.07), 1.18 (1.06 to 1.32), 1.32 (1.20 to 1.45) for women and 0.83 (0.73 to 0.93), 1.14 (1.04 to 1.25), 0.86 (0.78 to 0.95) for men. Age and SES adjusted RR (95% CI) for lung, colo-rectal and breast or prostate cancer were 0.89 (0.82 to 0.96), 1.17 (1.06 to 1.31), 1.31 (1.19 to 1.44) for women and 0.80 (0.75 to 0.86), 1.13 (1.04 to 1.24), 0.86 (0.78 to 0.95) for men.

Conclusion: There was a marked gradient by SES for lung cancer mortality for both people with and without T2DM with differing gradients for men with and without T2DM, possibly related to differing smoking habits and competing risks of mortality from cardiovascular disease. Compared to the non-diabetic population, T2DM was associated with higher mortality from colo-rectal cancer and breast cancer and lower mortality from lung and prostate cancer among men. Adjusting for SES had a small effect on overall RR for lung cancer but no effect for other cancers. There may be effect modification between T2DM and SES for lung cancer mortality among men.

Retrospective evaluation of the safety of exogenous insulin in people with type 2 diabetes: cardiovascular events, stroke, cancers, all-cause mortality and a combined endpoint

C.J. Currie¹, M. Evans², C.D. Poole¹, S. Jenkins-Jones³, C.L. Morgan¹;

¹Department of Public Health and Primary Care, Cardiff University,

²Department of Medicine, University Hospital of Wales, ³Department of Computer Science, Cardiff University, UK.

Background and aims: Recent observational and RCT data have raised concerns about the safety of treatment with exogenous insulin in people with type 2 diabetes. The purpose of this study was to compare outcome using alternative treatment regimens, and determine if this concern is warranted.

Materials and methods: Retrospective data were from UK general practices from 2000. The primary outcome was a combined endpoint of cardiovascular events, stroke, solid tumour cancers and all-cause mortality. Secondary endpoints were these constituent outcomes. Treatment cohorts were generated by characterising exposure to the following treatment regimens: metformin monotherapy vs. insulin-only regimens, insulin plus metformin combination therapies, sulfonylurea monotherapy, sulfonylurea plus metformin combination therapy, DPP-4s (monotherapy or in combination), and GLP-1s (monotherapy or in combination). Differences in baseline characteristics were accounted for using the Cox model (hazard ratio [HR] \pm 95%CI), with metformin monotherapy the referent.

Results: Cohort attribution was as follows: metformin, n=57,364 people (167,934 years follow-up); insulin-only 2,126 (9,268); insulin+metformin 2,158 (9,494); sulfonylurea 20,060 (64,193); sulfonylurea+metformin 16,464 (50,327); GLP-1s 757 (949); and DPP-4s 2,821 (3,125). The number of events was as follows: CV n=7,275, strokes 3,531, cancers 5,584, and deaths 8,424. The HRs are listed in the enclosed table following adjustment for potentially confounding characteristics.

Table. Adjusted hazard ratios for occurrence of diabetes-related endpoints by diabetes treatment.

	CV	Stroke	Cancer	Death	Combined
Insulin-only	1.85 (1.59-2.16)	1.69 (1.36-2.11)	1.63 (1.37-1.94)	2.54 (2.23-2.90)	1.99 (1.82-2.17)
Insulin+Met	1.54 (1.29-1.83)	1.02 (0.77-1.36)	1.47 (1.23-1.76)	1.61 (1.35-1.92)	1.52 (1.38-1.69)
Sulf	1.24 (1.13-1.35)	1.28 (1.16-1.42)	1.06 (0.97-1.16)	1.78 (1.66-1.90)	1.45 (1.39-1.51)
Sulf+Met	1.16 (1.06-1.27)	1.33 (1.19-1.48)	1.03 (0.94-1.12)	1.30 (1.20-1.41)	1.18 (1.12-1.23)
Metformin (ref)	1.00	1.00	1.00	1.00	1.00
GLP-1	0.84 (0.42-1.69)	1.95 (0.87-4.36)	1.11 (0.59-2.07)	1.05 (0.39-2.80)	0.85 (0.58-1.25)
DPP-4	0.91 (0.64-1.30)	1.31 (0.84-2.04)	0.83 (0.59-1.15)	0.82 (0.50-1.34)	0.74 (0.61-0.89)

Conclusion: Whilst accepting that a small group of patients require insulin replacement in type 2 diabetes, insulin-only regimens were consistently associated with the highest likelihood of progression to adverse outcomes. Together with biological plausibility and other intelligence, the safety and the role of exogenous insulin in type 2 diabetes is a concern and requires thorough scrutiny. Although there was relatively shorter follow-up, these data also demonstrated early promise for treatment with incretin-based therapies.

Incidence and type of cancer in Japanese subjects with type 2 diabetes

S. Honjo, Y. Kawasaki, Y. Hamamoto, K. Mori, Y. Wada, H. Ikeda, K. Nomura, H. Koshiyama;

Center for Diabetes & Endocrinology, The Tazuke Kofukai Medical Research Institute, Osaka, Japan.

Background and aims: An association between diabetes and cancer has long been speculated, but no conclusive evidence has been obtained.

Materials and methods: We prospectively investigated the frequency and type of cancer in Japanese subjects with type 2 diabetes. Subjects included a total of 3136 consecutive patients with type 2 diabetes, who visited our clinic during 27 months from January 2009 to March 2011.

Results: Among 3136 subjects, a total of 64 patients (2.0%) were newly diagnosed to have cancer. The mean age was 70[10] years and male/female ratio was 41/22. The most frequent site of cancer was colon (n=14), followed by pancreas (n=12), stomach (n=12), liver (n=6), bile duct (n=4), lung (n=3), breast (n=3), kidney (n=3), esophagus (n=2), and others. The double cancer was found in two subjects. The A1C at the diagnosis of cancer was 8.3[2.4]%, and the therapy for diabetes was diet and exercise only (n=8), oral antidiabetic drugs (OADs) (n=34) and insulin (n=22). They included eleven patients, who had recently visited our clinic during these 6 months. The therapeutic variations (diet and exercise only 12.5%, OADs 53.1%, and insulin 34.3%) of the patients with cancer were not significantly different from those without malignancy in our clinic (diet and exercise only 18.0%, OADs 42.9%, and insulin 39.1%). The subjects without any symptom and/or sign were 54.2%.

In the cases with cancer who had recently visited our clinic during these 6 months ($n=11$), 50% of them were found to have pancreatic cancer. This is in line with a previous report, suggesting that onset of diabetes preceded the diagnosis of asymptomatic pancreatic cancer. The mean HbA1c was significantly higher in the patients with pancreatic cancer than that in the patients with other cancers (9.6 % vs. 7.4%, $p<0.05$). Furthermore, among the patients with pancreatic cancer, seven of eleven of them were found to have new-onset diabetes.

Conclusion: The present registry indicated that the incidence of cancer was considerably high in Japanese patients with type 2 diabetes, and that the therapeutic intervention, such as insulin or metformin, might not affect the incidence of cancer. Furthermore, nearly half of them were without any symptom and/or sign, justifying the routine screening for malignancy in subjects with type 2 diabetes.

Limitations in the study of type 2 diabetes and pancreatic cancer in electronic insurance claims and health record databases

C.J. Girman¹, T.D. Kou¹, C.M. Alexander², E.A. O'Neill³, S. Engel⁴, B.J. Goldstein⁴, K.G. Brodovicz¹

¹Epidemiology, Merck, North Wales, ²Global Medical Affairs, Merck, North Wales, ³Global Scientific and Medical Publications, Merck, Rahway, ⁴Clinical Research - Metabolism, Merck, Rahway, USA.

Background and aims: While a higher incidence of pancreatic cancer (PC) has been associated with type 2 diabetes (T2D) in observational studies, the impact of reverse causality (impaired glucose metabolism as a consequence, rather than a cause, of PC) and tumor latency on this finding has not been adequately addressed. While electronic insurance claims and health record databases are valuable resources for the study of epidemiologic associations, the ability to consider reverse causality and latency is often limited. This study examined the impact of various latency periods on estimates of the incidence of PC in T2D and the association of T2D and subsequent PC in the General Practice Research Database (GPRD), an electronic health record database from the UK.

Materials and methods: A total of 3,127,581 patients (5.2% with T2D) were identified between 2003–2009 to assess the association of T2D and subsequent PC in patients diagnosed with T2D, relative to patients without T2D, using 1, 2, 3, and 5 year latency periods (time between T2D diagnosis or entry into study period and PC diagnoses). Patients with a history of PC were excluded. Multivariate Cox regression analyses adjusting for age, gender, prior history of chronic pancreatitis, gallbladder disease, obesity, smoking and alcohol use, and Charlson comorbidity index was used to estimate hazard ratios (HR) with 95% confidence intervals (CI).

Results: During this time, 1,934 patients were diagnosed with PC (442 with T2D, 1,492 without T2D). Patients with T2D consistently had a higher crude PC incidence compared to patients without T2D (table). Crude incidence increased with longer latency periods. Using all available data, crude incidence in patients with T2D was 78.8 per 100,000 vs. 11.6 per 100,000 in those without T2D. Using a 5 year latency period, crude incidence increased to 122.43 per 100,000 among patients with T2D and 25.89 per 100,000 in those without T2D. Adjusted HRs remained significant but point estimates attenuated slightly with longer latency periods. With a 5-year latency period, the adjusted HR was 1.5 (95% CI 1.06, 2.12), compared to a range from 1.80–1.84 with shorter or no latency periods.

Conclusion: Studies of the association of T2D and PC should account for reverse causality and latency to avoid underestimating PC incidence in patients with T2D and overestimating the HR. This is also relevant to studies of T2D treatments. These elements are often difficult to assess in electronic claims data due to the shorter duration of follow-up available. Electronic health record data can have the advantage of longer follow-up time and more complete data on potential confounders. However, even in an excellent electronic health record database such as GPRD, patient numbers decline quickly for rare conditions with long latency periods such as PC.

Latency Period	crude incidence rate per 100,000			
	Total cohort	T2D	Without T2D	Adjusted HR (95% CI)
Full cohort (n=1,934)	14.40	78.80 n=442	11.60 n=1,492	1.84 (1.56, 2.17)

776

Synergistic effect of type 2 diabetes and history of chronic pancreatitis on pancreatic cancer risk: a retrospective cohort study from the General Practice Research Database (GPRD)

K.G. Brodovicz¹, T.D. Kou¹, C.M. Alexander², E.A. O'Neill³, S. Engel⁴, C.J. Girman¹

¹Epidemiology, Merck, North Wales, ²Global Medical Affairs, Merck, North Wales, ³Global Scientific and Medical Publications, Merck, Rahway, ⁴Clinical Research - Metabolism, Merck, Rahway, USA.

Background and aims: The causes of pancreatic cancer (PC) remain largely unknown. Alcohol and tobacco use, gallbladder disease, and obesity are known risk factors. Many of these risks are also associated with chronic pancreatitis and type 2 diabetes (T2D). This study examined a potential synergistic association between T2D and chronic pancreatitis on PC risk in a retrospective cohort study in the GPRD.

Materials and methods: Data from 3,127,581 patients, 163,791 (5.2%) with T2D, identified between 2003–2009 were analyzed. Any past medical encounter for obesity (BMI \geq 30), chronic pancreatitis, or gallbladder disease occurring before a patient's index date were evaluated at baseline. Index date was the date of T2D diagnosis or date of entry into the study period for patients with existing T2D or no T2D. Patients with a history of PC were excluded. Multivariate Cox regression analysis covariates included Charlson comorbidity index and any known prior exposure to lifestyle risk factors such as tobacco and alcohol use. Crude and adjusted hazard ratios (HR) with 95% confidence intervals (CI) were calculated.

Results: During this time, 1,934 patients were diagnosed with PC (442 with T2D, 1,492 without T2D). T2D patients without a history of chronic pancreatitis had an elevated PC risk compared to patients without T2D and no history of chronic pancreatitis (adjusted HR = 3.00, 95%CI: 2.67, 3.37). Likewise, patients with chronic pancreatitis but without T2D had a 2-fold elevated risk, compared to those without either condition, but there were only 5 cases of PC in this group and the HR did not reach significance (HR: 2.3; 0.95, 5.56). Patients with T2D and a history of chronic pancreatitis had a much higher PC risk compared to patients without T2D and no history of chronic pancreatitis (adjusted HR = 14.96, 95%CI: 7.99, 28.02). Other risk factors associated with increased PC risk included age, alcohol use, and tobacco use.

Conclusion: After adjusting for known risk factors, T2D and chronic pancreatitis had a synergistic association on increased risk of PC compared to patients without T2D and without a history of chronic pancreatitis.

	N	Number of PC Cases	Adjusted HR	95% CI
Patients with no diabetes and no pancreatitis	2,960,982	1,487	1.00	
Patients with no diabetes and with pancreatitis	2,808	5	2.30	0.95, 5.56
Patients with T2D and no pancreatitis	162,741	432	3.00	2.67, 3.37
Patients with T2D and pancreatitis	1,050	10	14.96	7.99, 28.02

PS 062 Exenatide: twice daily to once weekly

777

Exenatide twice daily: a retrospective analysis of pooled exenatide clinical trial efficacy data stratified by race, age, duration of diabetes, BMI and gender

R. Pencek¹, P.W. Anderson², A. Blickensderfer¹, Y. Li¹, S. Brunell¹

¹Amylin Pharmaceuticals, Inc., San Diego, ²Eli Lilly and Company, Indianapolis, USA.

Background and aims: Many factors can influence the efficacy and safety of antidiabetic drug therapies including race, age, duration of diabetes, BMI, and gender. The purpose of this post hoc analysis was to examine endpoints, stratified by various subgroups, with the use of pooled clinical data from major exenatide BID (ExBID) trials.

Materials and methods: Patients included in this analysis had type 2 diabetes and received 10 µg ExBID in 12 comparator- or placebo-controlled studies. Mean changes from baseline, and corresponding 95% CI, were used to summarize efficacy endpoints for each group.

Results: A total of 1,877 patients were included (age [mean±SD] 57±10 y, HbA1c 8.3±1.0%, weight 93.0±19.3 kg; analysis endpoints at 24–30 weeks). [see table for results] Patients treated with ExBID experienced improvements in HbA1c, fasting glucose (FG), and weight loss from baseline, irrespective of age, duration of diabetes, or race. The reduction in FG was not as substantial in Blacks as it was in other racial groups; the lower baseline FG level in Blacks compared with that of other racial groups (8.2 mmol/L vs 9.2–9.9 mmol/L) may have contributed to this effect. Analyses of the BMI and gender subgroups showed similar efficacy results (data not shown). Overall, the most common adverse events were nausea (39.2%), vomiting (14.3%), and diarrhea (12.3%). Hypoglycaemia was more frequent in patients receiving sulphonylurea. Limitations of this post hoc analysis include a small number of patients in some groups, a lack of controls, and no adjustment for potentially confounding variables.

Conclusion: Patients treated with ExBID experienced improvements in HbA1c, FG, and weight loss from baseline, irrespective of age, duration of diabetes, race, BMI, or gender.

DURATION-3: changes in cardiovascular risk factors observed in patients with type 2 diabetes after 84-week therapy with exenatide once weekly or insulin glargine

M. Diamant¹, L. VanGaal², S. Stranks³, B. Guerci⁴, L. MacConell⁵, M. Chan⁶, M. Trautmann⁶

¹Diabetes Center, VU University Medical Center, Amsterdam, Netherlands,

²Department of Diabetology, Metabolism and Clinical Nutrition, Antwerp University Hospital, Belgium, ³Southern Adelaide Diabetes and Endocrine Services, Australia, ⁴Diabetology, Nutrition, Metabolic Disorders, Brabo Hospital & Center of Clinical Investigation, Vandoeuvre-Les-Nancy, France, ⁵Amylin Pharmaceuticals, Inc., San Diego, ⁶Eli Lilly and Company, Indianapolis, USA.

Background and aims: In the DURATION-3 study, 456 patients with type 2 diabetes who did not achieve adequate glycaemic control on metformin alone or in combination with sulphonylurea were randomized to add exenatide once weekly (EQW) or insulin glargine once daily (IG). The majority of patients had abnormal lipids and/or BP at baseline. Patients in the EQW group experienced superior improvements in glycaemic control as measured by HbA1c compared to those in the IG group in the 26-week core study. EQW also was associated with significant weight loss as opposed to weight gain with IG. In post-hoc analyses, patients on EQW or IG experienced clinically significant changes in several surrogate markers of cardiovascular (CV) risk; those with abnormal baseline CV risk factors showed the greatest improvements. A study extension of up to 2.5 y was planned to evaluate sustained use of EQW in a controlled setting. Here we present interim data.

Materials and methods: Patients who entered the extension study remained on the initial therapy that they were assigned to for a total of up to 84 weeks. We repeated the post hoc analyses to assess changes in CV risk factors in patients with abnormal baseline values (defined in Table) and correlations between CV risk factors and body weight changes. We further analyzed 84-week data to determine whether patients achieved the following composite endpoints: Percentage of patients with HbA1c <7% (goal 1) or ≤6.5% (goal 2) plus SBP <130 mmHg and LDL <2.586 mmol/L.

Results: A total of 346 patients completed 84 weeks of therapy (EQW, 173; IG, 173). Patients with abnormal baseline values in both treatment groups continued to experience improvements in CV risk factors at week 84 (table). Body weight reductions also continued in the EQW group, while body weight continued to increase in the IG group: treatment difference -4.46 (0.30 kg) $P<0.001$. Body weight change for patients in the IG group was significantly correlated with change in SBP ($r^2=0.01736$, $P=0.0499$) and DBP ($r^2=0.02931$, $P=0.0106$). Significantly more patients in the EQW group achieved composite endpoint goal 1 (EQW: 15.7%, IG: 7.9%; $P=0.012$) and goal 2 (EQW: 11.2%, IG: 5.1%; $P=0.020$). The rate of new cases of adverse events declined after 26 weeks of treatment.

Conclusion: These data from patients receiving EQW for 84 weeks demonstrate its potential to be a long-term therapeutic option especially for the many patients with type 2 diabetes who fail to achieve blood glucose control while on oral agents and who have elevated CV risk factors.

Table. Mean Changes in Cardiovascular Risk Factors at Week 84

	SBP, mmHg	DBP, mmHg	LDL-C, mmol/L	HDL-C, mmol/L	TG, mmol/L	TC, mmol/L	hsCRP, mg/L

DURATION-4: Improvements in glucose control and cardiovascular risk factors in patients with type 2 diabetes treated with exenatide once weekly, metformin, pioglitazone, or sitagliptin

M.K. Boardman¹, M. Hanefeld², A. Kumar³, J.G. Gonzalez⁴, L. de Teresa⁵, J. Northrup¹, M. Chan¹, D. Russell-Jones⁶

¹Eli Lilly and Company, Indianapolis, USA, ²Center for Clinical Studies, Technical University Dresden, Germany, ³Diabetes Care and Research Center, Patna, India, ⁴Servicio de Endocrinología, Hospital Universitario, Monterrey, Mexico, ⁵Medicina Innovadora, Clínica Mediterránea de Neurociencias, Alicante, Spain, ⁶Department of Diabetes and Endocrinology, Royal Surrey County Hospital, Guildford, UK.

Background and aims: Type 2 diabetic subjects have elevated cardiovascular (CV) risk factors including varying degrees of hypertension and dyslipidemia. We examined glycaemic control (primary), CV risk factors (secondary), and composite endpoint goals (exploratory) in drug-naïve subjects randomised to receive exenatide once weekly (EQW) vs. metformin (MET), pioglitazone (PIO), or sitagliptin (SITA) for 26 weeks.

Materials and methods: Patients in this double-blind study were randomised to subcutaneous (SC) EQW 2.0mg + oral placebo (PBO, N=248), MET + weekly SC PBO (N=246), PIO + weekly SC PBO (N=163), and SITA 100mg/d + weekly SC PBO (N=163). Baseline characteristics were: male, 59%; Caucasian, 67%; age, 54 y; HbA1c, 8.5%; fasting serum glucose (FSG), 9.9 mmol/L; body weight, 87.0 kg; and diabetes duration, 3.0 y (means). Changes in lipid-lowering and antihypertensive agents were only allowed if medically necessary. Post hoc analyses performed: 1) Change in CV risk factors (baseline abnormal); 2) Correlations between changes in risk factors and body weight for each treatment and; 3) Composite goals (Goal A - % of patients with HbA1c <7%, no weight gain, no minor or major hypoglycaemia at endpoint; Goal B - % with HbA1c <7%, systolic BP <130 mmHg, LDL <2.6 mmol/L at endpoint). **Results:** HbA1c reductions (%) at 26 weeks (least-squares [LS] means) with EQW vs. MET, PIO, and SITA were -1.53 vs. -1.48 (p=0.620), -1.63 (p=0.328), and -1.15 (p<0.001), respectively. LS mean changes in weight (kg) were -2.0 vs. -2.0 (p=0.892), +1.5 (p<0.001), and -0.8 (p<0.001), respectively. Except for total cholesterol, >50% of patients had abnormal lipids and blood pressure at baseline. Blood pressure and fasting lipids improved from baseline abnormal in all treatment groups (Table 1). Body weight change was not correlated to CV risk factors for EQW and PIO; weakly correlated with change in HDL (r²=0.04, p=0.003) and TG (r²=0.03, p=0.01) for MET; and weakly correlated with SBP (r²=0.04, p=0.01) and hsCRP (r²=0.04, p=0.03) for SITA. Composite goals were achieved most often with EQW and MET: 48% achieved Goal A for EQW vs. 46% (MET), 22% (PIO), and 35% (SITA); 16% achieved Goal B for EQW vs. 13%, 10%, and 7%.

Conclusion: Although all comparators improved glycaemic control at 26 weeks, variation was demonstrated with improvements in individual CV risk factors including body weight. EQW and MET were associated with greater achievement of composite goals of clinical relevance.

Efficacy and safety of exenatide once weekly across background therapies: a pooled analysis of DURATION studies

J. Malone¹, B. Walsh², R. Pencek², Y. Li², D. Bruhn¹

¹Eli Lilly and Company, Indianapolis, ²Amylin Pharmaceuticals, Inc., San Diego, USA.

Background and aims: Treatment with the GLP-1 receptor agonist exenatide once weekly (QW) in patients with type 2 diabetes on a broad range of background therapies, ranging from diet and exercise to combination oral therapy, resulted in HbA1c reduction and weight loss (the DURATION clinical trials). It is of clinical interest to understand the safety and efficacy of exenatide QW across these background treatments.

Materials and methods: A pooled analysis by background therapy was performed on Intent-to-Treat (ITT) patients who initiated exenatide QW in the 24-30 week controlled periods of all four completed DURATION trials included in an ongoing integrated database (DURATION-1, -2, -3, and -5). For all efficacy endpoints, means and standard deviations were summarized for baseline values and means and 95% CI were reported for the change from baseline. Safety was reported as overall incidence.

Results: HbA1c and fasting glucose (FG) were significantly reduced with exenatide QW across all background therapies (Table). Weight loss was observed with exenatide QW in all cohorts, but did not reach statistical significance in the small cohort of patients on metformin (MET)+ thiazolidinedione (TZD) background. Nausea, the most frequent adverse event, occurred in 9% of patients who received exenatide QW monotherapy (diet/exercise) vs. 20%, 14%, and 35% for MET, MET+ sulphonylurea (SU), and MET+TZD background therapies, respectively. Nausea led to withdrawal in only 4 patients. Overall hypoglycaemia incidence (including unconfirmed symptoms of hypoglycaemia) was 33% in patients with MET+SU background vs. 7%, 8%, and 12% for diet/exercise, MET, and MET+TZD background therapies, respectively. One episode of hypoglycaemia necessitated the assistance of another person, but did not require medical intervention or involve loss or severe impairment of consciousness.

Conclusion: Patients treated with exenatide QW exhibited similar improvements in glycaemic control and body weight irrespective of background therapy.

Background Therapy	Diet/Exercise	MET	MET+TZD	MET+SU
DURATION Trial	1, 5	1, 2, 3, 5	1, 5	1, 3, 5
N	43	427	26	150
HbA1c Baseline (%)	8.4±1.1	8.4±1.1	8.1±1.0	8.5±1.1
Δ HbA1c (%)	-1.6 (-2.0, -1.2)	-1.4 (-1.6, -1.3)	-1.5 (-1.8, -1.2)	-1.5 (-1.6, -1.3)
HbA1c <7% at endpoint	72%	63%	65%	53%
HbA1c ≤6.5 % at endpoint	47%	42%	50%	39%
FG Baseline (mmol/L)	9.2±2.4	9.4±2.6	8.8±2.8	10.1±3.0
Δ FG (mmol/L)	-1.9 (-2.7, -1.1)	-1.9 (-2.2, -1.7)	-2.0 (-3.1, -1.0)	-2.0 (-2.5, -1.4)

Effects of exenatide once weekly on glycaemic goals and selected cardiovascular risk factors in patients with type 2 diabetes: a retrospective analysis of pooled clinical trial data

M. Wintle, A. Meloni, M.B. DeYoung, Y. Li, J. Yan, J. Malloy; Amylin Pharmaceuticals, Inc., San Diego, USA.

Background and aims: Minimizing the most common cardiovascular and microvascular risks associated with type 2 diabetes (T2DM) is of primary concern in therapeutic decision making. Achieving early glycaemic control (HbA1c ≤6.5%) without hypoglycaemia has emerged as an important consideration. Beyond glycaemic control, therapeutic effects on established cardiovascular risk factors such as body weight, systolic blood pressure (SBP), and low-density lipoprotein (LDL) measurements are also clinically important. This retrospective pooled analysis from the DURATION clinical trial program for exenatide once weekly (ExQW) assessed the percentage of patients

achieving glycaemic goals. Additionally, changes from baseline in SBP and LDL were measured.

Materials and methods: The DURATION trials compared the efficacy (HbA1c) and safety of ExQW vs glucose-lowering comparators administered to patients for 24–30 weeks. Data from 804 patients who completed at least 20 weeks of ExQW exposure (defined as the completer population) were pooled and then stratified to identify patients who were not already at HbA1c goal at baseline (HbA1c >6.5%, $n = 800$; HbA1c $\geq 7\%$, $n = 774$). Patients were further stratified to isolate subpopulations of patients who were 1) not at recommended SBP measurements (SBP ≥ 130 mmHg) at baseline or 2) not at recommended LDL measurements (LDL ≥ 2.59 mmol/L) at baseline. The percentage of patients not already at goal who achieved glycaemic goals without hypoglycaemia or weight gain was assessed. Additionally, the mean changes in SBP and LDL from baseline to endpoint were assessed in the stratified populations.

Results: The baseline characteristics of the completer population were 45.0% women, mean age of 55 years, and a mean HbA1c of 8.4%. The results showed that 46.6% of patients achieved an HbA1c $\leq 6.5\%$ at endpoint and 64.6% of patients achieved an HbA1c <7% at endpoint. The percentage of patients able to achieve these goals without hypoglycaemia was 42.8% and 60.3% and without hypoglycaemia and weight gain was 36.8% and 50.1% for HbA1c $\leq 6.5\%$ and <7%, respectively. The mean \pm SEM change in HbA1c from baseline to endpoint in patients not already at HbA1c goal at baseline was $-1.52 \pm 0.04\%$ for the HbA1c $\leq 6.5\%$ goal and $-1.55 \pm 0.04\%$ for the HbA1c <7% goal. SBP and LDL improved in those patients not at the recommended goals for SBP or LDL at baseline. The mean \pm SEM change in SBP from baseline in the SBP ≥ 130 mmHg (at baseline) population was -7.41 ± 0.71 mmHg ($P < 0.0001$) and the mean \pm SEM change in LDL from baseline in the LDL ≥ 2.59 mmol/L (at baseline) population was -0.31 ± 0.04 mmol/L ($P < 0.0001$). No clinically significant changes in the mean SBP or LDL were noted in those patients treated with ExQW who were at the recommended SBP and LDL measurements at baseline. Adverse events in this analysis were consistent with those reported in the individual trials with nausea and diarrhea being most frequently reported.

Conclusion: This analysis demonstrated that in this population, treatment with ExQW significantly improved the percentage of patients achieving an HbA1c $\leq 6.5\%$ or <7% without causing hypoglycaemia or weight gain. Furthermore, in patients not at SBP or LDL goals, clinically meaningful improvements in SBP and LDL were observed.

Exenatide once weekly: a retrospective analysis of pooled exenatide clinical trial efficacy data stratified by race, age, duration of diabetes, BMI and gender

A. Blickensderfer¹, R. Pencek¹, Y. Li¹, S. Brunell¹, P.W. Anderson²;

¹Amylin Pharmaceuticals, Inc., San Diego, ²Eli Lilly and Company, Indianapolis, USA.

Background and aims: Many factors can influence the efficacy and safety of antihyperglycaemic drug therapies including race, age, duration of diabetes, BMI, and gender. The purpose of this post hoc analysis was to examine endpoints, stratified by various subgroups, with the use of pooled clinical trial data from major exenatide once weekly (ExQW) trials.

Materials and methods: Patients included in this analysis had type 2 diabetes and received exenatide in 4 comparator-controlled ExQW studies. Mean changes from baseline, and corresponding 95% CI, were used to summarize efficacy endpoints for each group.

Results: A total of 670 patients were included (age [mean \pm SD] 55 ± 10 y, HbA1c $8.4 \pm 1.1\%$, weight 94.1 ± 19.8 kg; analysis endpoints at 24–30 weeks). [see table for results] Patients treated with ExQW experienced improvements in HbA1c, fasting glucose (FG), and weight loss from baseline, irrespective of age, duration of diabetes, or race. Similar efficacy results emerged in the analyses of the BMI and gender subgroups (data not shown). Overall, the most common adverse events were nausea (18.8%), diarrhea (12.4%), and headache (8.2%). Minor hypoglycaemia occurred in 5% of patients; a single instance of hypoglycaemia occurred that necessitated the assistance of another person, but did not require medical intervention or involve loss or severe impairment of consciousness. Limitations of this post hoc analysis include a small number of patients in some groups, a lack of controls, and no adjustment for potentially confounding variables.

Conclusion: Patients treated with ExQW experienced improvements in HbA1c, FG, and weight loss from baseline, irrespective of age, duration of diabetes, race, BMI, or gender.

	Age		Duration of Diabetes		Race

Exenatide once weekly: sustained improvement in glycaemic control and weight loss through 3 years

D. Maggs, B. Walsh, Y. Li, R. Pencek, L. MacConell;

Amylin Pharmaceuticals, Inc., San Diego, USA.

Background and aims: In a 30-week controlled trial (DURATION-1), the once-weekly formulation of the GLP-1 receptor agonist exenatide (exenatide QW) elicited a more robust glucose lowering effect than the BID formulation of exenatide (ITT Δ HbA1c: -1.9% vs. -1.5%), coupled with similar weight loss, in patients with type 2 diabetes on a range of background therapies. This analysis was conducted to evaluate safety and efficacy following 3 years of treatment.

Materials and methods: The controlled period of the DURATION-1 trial was followed by an open-ended, open-label period in which all patients either continued exenatide QW treatment or switched from exenatide BID to exenatide QW. All efficacy endpoints were analyzed using the 3-year completer population. Means and standard deviations of the baseline values were summarized. Least square means and 95% confidence intervals based on general linear models were reported for the change from baseline. Adverse events are reported as overall incidence in the ITT population.

Results: Approximately 66% ($n=194$) of the 295 ITT patients completed 3 years of treatment (baseline [mean \pm SD]: HbA1c $8.2 \pm 1.0\%$; fasting plasma glucose (FPG) 9.3 ± 2.4 mmol/L; weight 101 ± 18 kg; duration of diabetes 7 ± 5 y; therapy at screening: diet/exercise [15%], metformin (MET) [33%], MET+sulphonylurea (SU) [29%], MET+thiazolidinedione (TZD) [9%]). Significant HbA1c improvement (LS mean [95%CI]) was observed with 3 years of treatment (-1.6% [-1.7, -1.4]), resulting in a mean \pm SEM HbA1c of $7.0 \pm 0.1\%$ (57% achieved HbA1c $\leq 7.0\%$ and 32% achieved an HbA1c $\leq 6.5\%$). Significant improvements in FPG (-1.8 mmol/L [-2.1, -1.5]); mean FPG at year 3: 7.3 ± 0.1 mmol/L and weight (-2.3kg [-3.4, -1.2]) were also observed. Furthermore, 3 years of treatment was associated with the following changes in cardiovascular risk markers: systolic blood pressure (-2.1 mmHg [-4.5, 0.2]), diastolic blood pressure (-2.0 mmHg [-3.3, -0.7]), total cholesterol (-0.26 mmol/L [-0.40, -0.11]), LDL cholesterol (-0.18 mmol/L [-0.31, -0.05]), and triglycerides (-12% [-18, -6]; geometric LS mean % change). Nausea (predominantly mild) was the most common adverse event with exenatide QW during the initial controlled period (27%), and decreased over time (16% from weeks 30–156). Injection-site pruritus and erythema were infrequent (<5%) from week 30–156 (vs 18% and 7%, respectively, in the 30-week controlled period). Treatment-emergent events leading to withdrawal from week 30–156 were also infrequent (3%), consistent with the 30-week controlled trial period (6%). As observed during the first 30 weeks of the trial, no major hypoglycaemia was observed in this open-label treatment period; incidence of minor hypoglycaemia was low in this treatment period, occurring predominantly with concomitant SU (16% incidence in patients on SU vs only 1% in patients not receiving concomitant SU; 15% and 0% incidence, respectively, during the controlled 30-week period). Correcting for cumulative exposure (patient-years), the adverse event incidence rates were lower in the open-label period when compared to rates observed in the initial controlled period.

Conclusion: Exenatide QW elicited a robust and sustained improvement in glycaemic control in patients with type 2 diabetes who were on an array of background treatments. Importantly, this effect was associated with improvements in broader cardiometabolic measures, including body weight and lipids.

Efficacy and safety of lixisenatide once-daily versus placebo in patients with type 2 diabetes mellitus insufficiently controlled on metformin (GetGoal-F1)

G. Bolli¹, M. Munteanu², S. Dotsenko³, E. Niemoeller⁴, G. Boka⁵, M. Hanefeld⁶,

¹University of Perugia, Italy, ²University of Medicine and Pharmacy “Victor Babes”, Timisoara, Romania, ³Zaporyzhzha State Medical University, Ukraine, ⁴sanofi aventis, Frankfurt, Germany, ⁵sanofi aventis, Chilly-Mazarin, France, ⁶Centre for Clinical Studies, GWT-TUD GmbH, Dresden, Germany.

Background and aims: This randomised, double-blind, placebo-controlled, parallel-group, multicentre study compared the efficacy and safety of lixisenatide QD in two dose-increase regimens vs placebo as add-on therapy in T2DM inadequately controlled by metformin.

Materials and methods: Patients with T2DM (n=482) treated with metformin (mean age 56.1 yr, diabetes duration 6.0 yr, BMI 32.5 kg/m², HbA_{1c} 8.0%) were randomised to one of 4 QD regimens: lixisenatide 2-step dose increase (10 µg for 1 wk, 15 µg for 1 wk then 20 µg; n=161), lixisenatide 1-step dose increase (10 µg for 2 wk then 20 µg; n=161), placebo 2-step (n=79) or placebo 1-step (n=81) (placebo groups were combined). After screening of up to 3 wk, patients entered a 24-wk main treatment period, followed by a variable extension of at least 52 wk, with lifestyle advice every 3 mo. The primary objective was to assess the efficacy of lixisenatide (2-step regimen) vs placebo in terms of HbA_{1c} reduction at Wk 24. Efficacy of the 1-step regimen was the next test in a step-down testing procedure.

Results: The 24-wk main treatment period data are presented. There were significant improvements in HbA_{1c} from baseline to Wk 24 in both lixisenatide groups vs placebo (p<0.0001) (Table). Significantly more patients in the lixisenatide groups achieved HbA_{1c} ≤6.5% (20.4% 2-step, 25.6% 1-step) and <7.0% (42.1% 2-step, 47.4% 1-step) vs placebo (7.6% and 24.1%, respectively; p<0.001). There were also significant improvements in FPG and body weight with lixisenatide vs placebo (Table). Rates of premature treatment discontinuation at Wk 24 were 10.6% in the lixisenatide 2-step, 8.7% in the 1-step and 5.6% in the placebo groups. Fewer patients required rescue therapy in both lixisenatide groups than in the placebo group (3.1% [2-step] and 1.3% [1-step] vs 4.4%). The incidence of patients with serious AEs was comparable in the lixisenatide groups (4.3% [2-step]; 3.1% [1-step]) and the placebo group (2.5%). The overall incidence of patients with AEs was 70.8% for lixisenatide 2-step, 67.7% for 1-step and 65.6% for placebo. The most frequently reported AEs were nausea (35.4% [2-step] and 26.1% [1-step] vs 0% with placebo) and vomiting (15.5% [2-step] and 11.8% [1-step] vs 0% with placebo). No significant difference was seen in the % of patients with symptomatic hypoglycaemia between the lixisenatide groups (2.5% [2-step]; 1.9% [1-step]) and placebo (0.6%; p>0.1). There were no cases of severe hypoglycaemia.

Conclusion: Lixisenatide QD administered in a 1- or 2- dose increase regimen significantly improved glycaemic control and decreased weight over 24 wks with no increased risk of hypoglycaemia in T2DM patients insufficiently controlled on metformin.

Efficacy and safety of lixisenatide once-daily versus placebo in patients with type 2 diabetes mellitus insufficiently controlled on sulfonylurea ± metformin (GetGoal-S)

R.E. Ratner¹, M. Hanefeld², P. Shamanna³, K. Min⁴, G. Boka⁵, P. Miossec⁶, I. Muehlen-Bartmer⁷, J. Rosenstock⁸

¹MedStar Research Institute, Hyattsville, USA, ²Centre for Clinical Studies, GWT-TUD GmbH, Dresden, Germany, ³Bangalore Diabetes Centre, India, ⁴Eulji General Hospital, Seoul, Republic of Korea, ⁵sanofi aventis, Chilly-Mazarin, France, ⁶sanofi aventis, Paris, France, ⁷sanofi aventis Deutschland GmbH, Frankfurt, Germany, ⁸Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA.

Background and aims: This randomised, double-blind, placebo-controlled, two-arm, parallel-group, multicentre study compared the efficacy and safety of once-daily (QD) lixisenatide vs placebo as add-on therapy in people with T2DM inadequately controlled by sulfonylurea ± metformin.

Materials and methods: A total of 859 patients with T2DM treated with a sulfonylurea ± metformin (16% on sulfonylurea alone, mean age 57.2 yrs, diabetes duration 9.4 yrs, BMI 30.2 kg/m², baseline HbA_{1c} 8.3%) were randomised to lixisenatide 20 µg QD (n=573) or placebo (n=286) in a 2-step dose increase regimen. After a screening period of up to 3 weeks, patients entered a 24-week main treatment period, followed by a variable extension of at least 52 weeks. The primary objective was to assess the efficacy of lixisenatide vs placebo in terms of HbA_{1c} reduction at Week 24.

Results: The 24-week main treatment period data are presented. Lixisenatide QD significantly reduced HbA_{1c} compared to placebo (-0.85 vs -0.10%; p<0.0001). Lixisenatide QD vs placebo also significantly improved 2-hour PPG (after a standardised meal test) (-6.19 vs -0.21 mmol/L), FPG (-0.99 vs -0.36 mmol/L) and body weight (-1.76 vs -0.93 kg) and increased the proportion of patients achieving HbA_{1c} <7.0% (36.4 vs 13.5%) (p<0.0001 for all; see Table). The percentage of patients requiring rescue therapy was significantly lower in the lixisenatide group than in the placebo group (3.5% and 12.0% respectively, p<0.0001). Rates of premature treatment discontinuation at Week 24 were 12.9% in the lixisenatide group and 10.8% in the placebo group. The overall incidence of patients with adverse events (AEs) was 68.3% in the lixisenatide group and 61.1% in the placebo group. The difference between groups was mainly attributable to GI events, mainly nausea (25.3% with lixisenatide vs 7.0% with placebo) and vomiting (8.7% vs 3.5%). No difference was seen in the incidence of patients with serious AEs between lixisenatide (3.5%) and placebo (5.6%). Lixisenatide QD did not significantly increase symptomatic hypoglycaemia vs placebo (Table). There was 1 case (0.2%) of severe hypoglycaemia in the lixisenatide group and none in the placebo group.

Conclusion: Add-on treatment with lixisenatide once-daily significantly improved glycaemic control with weight loss, without increasing the risk of hypoglycaemia, over 24 weeks in T2DM patients insufficiently controlled on sulfonylurea ± metformin.

Efficacy and safety of lixisenatide once-daily versus exenatide twice-daily in patients with type 2 diabetes insufficiently controlled on metformin (GetGoal-X)

J. Rosenstock¹, D. Raccach², L. Korányi³, L. Maffei⁴, G. Boka⁵, P. Miossec⁶, J.E. Gerich⁷

¹Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA, ²University Hospital Sainte Marguerite, Marseille, France, ³DRC Ltd, Balatonfüred, Hungary, ⁴Investigación Clínica Aplicada, Buenos Aires, Argentina, ⁵sanofi aventis, Chilly-Mazarin, France, ⁶sanofi aventis, Paris, France, ⁷University of Rochester School of Medicine, USA.

Background and aims: This randomised, open-label, active-controlled, parallel-group, multicentre study compared the efficacy and safety of lixisenatide QD vs exenatide BID as add-on therapy in T2DM inadequately controlled on metformin monotherapy.

Materials and methods: Individuals with T2DM (n=634) treated with metformin ≥1.5 g/day (mean age 57.4 yr, diabetes duration 6.8 yr, BMI 33.6 kg/m², HbA_{1c} 8.0%) were randomised to lixisenatide 20 µg QD (n=318) or exenatide 10 µg BID (n=316). After a screening period of up to 2 wk, subjects entered a 24-wk main treatment period, followed by a variable extension of at least 52 wk. Both groups received a stepwise increase in dose up to a maximum 20 µg/day. The primary objective was to demonstrate non-inferiority of lixisenatide to exenatide in terms of HbA_{1c} reduction at Wk 24. Non-inferiority was demonstrated if the upper limit of the 2-sided 95% CI of the difference between lixisenatide and exenatide in adjusted mean change in HbA_{1c} from baseline to Wk 24 was ≤0.4%.

Results: The 24-wk main treatment period data are presented. Lixisenatide QD achieved its primary endpoint of non-inferiority in HbA_{1c} reduction from baseline [BL] at Wk 24 vs exenatide BID (Table). Improvements in mean FPG and the proportion of subjects achieving HbA_{1c} <7.0% were comparable between groups (Table). Mean body weight significantly decreased from BL in both groups: 94.5 to 91.7 kg with lixisenatide and 96.7 to 92.9 kg with exenatide. The incidence of subjects with adverse events (AEs) was similar for lixisenatide (69.5%) and exenatide (72.2%). Rates of premature treatment discontinuation were 12.9% and 14.2% for lixisenatide and exenatide, respectively, and discontinuations due to AEs (mainly GI events) were 33 (10.4%) in lixisenatide and 41 (13.0%) in exenatide subjects. Serious AEs occurred in 9 lixisenatide (2.8%) and 7 exenatide (2.2%) subjects. Significantly fewer subjects experienced symptomatic hypoglycaemia with lixisenatide, with 6-fold fewer hypoglycaemic events with lixisenatide (Table). There were no cases of severe hypoglycaemia. Overall GI tolerability appeared better for lixisenatide vs exenatide, with fewer experiencing nausea and vomiting (Table). More subjects in the lixisenatide group tolerated the targeted maintenance dose of 20 µg/day (93% vs 83% exenatide).

Conclusion: Add-on lixisenatide QD in T2DM insufficiently controlled on metformin demonstrated non-inferior improvements in HbA_{1c}, but with less

hypoglycaemia, slightly less weight loss and a more favourable GI tolerability profile compared with exenatide BID at Wk 24.

A placebo controlled single ascending dose Phase 1 for safety, tolerability, pharmacokinetics and pharmacodynamics of VRS-859 in patients with T2DM

J.L. Cleland¹, C.R. Shore², M.S. Kipnes³;

¹Diartis Pharmaceuticals, Mountain View, ²Versartis, Inc., Mountain View,

³Cetero Research, San Antonio, USA.

Background and aims: VRS-859 is a novel fusion protein containing the GLP-1 analogue, exenatide, and a long hydrophilic tail of natural amino acids, XTEN, which increases the half-life. VRS-859 is being developed as a once monthly injection for the treatment of type 2 diabetes mellitus (T2DM).

Materials and methods: Up to 55 T2DM patients on metformin (met) or met and sulfonylurea (SU) are proposed for the study to evaluate the safety/tolerability, pharmacokinetics (PK) and pharmacodynamics (PD) of VRS-859. T2DM patients on met+SU are withdrawn from SU treatment 2 weeks prior to dosing and remain on met only. Each patient receives a single subcutaneous dose of VRS-859 or placebo on Day 1. Dose levels are 12.5, 25, 50, 100 and 150 mg VRS-859. In each treatment group, 8 patients receive a single dose level of VRS-859 and 3 patients receive placebo in a randomized blinded manner. PD measurements (fasting glucose (FG) and insulin and oral glucose tolerance test (oGTT)) are performed on Days -1, 4, 8, 11, 15, 18, 22, 25, and 30. Safety assessments including calcitonin, lipase, and amylase levels as well as QTc analyses are performed through Day 30. Anti-VRS-859 antibody analyses are performed at Day -1, Day 30 and on follow-up at Day 60.

Results: This clinical study is ongoing with patients currently enrolling in the 100 mg dose cohort, the dose expected to provide once monthly therapy. To date, 29 patients have been enrolled: 8 patients received 12.5 mg VRS-859, 8 patients received 25 mg VRS-859, 6 patients received 50 mg VRS-859, and 7 patients received placebo. In patients treated with VRS-859, no notable AEs and no changes in QTc have been observed. No anti-VRS-859 antibodies have been detected. The PK of VRS-859 indicated a T_{max} of approximately 3 days post-dose and a half-life of approximately 120 hrs. The mean reduction in FG from baseline at Day 4 and Day 8 for patients receiving 25 mg VRS-859 was 36.7 mg/dL and 25.9 mg/dL, respectively. The mean reduction in glucose AUC after oGTT compared to baseline at Day 4 and Day 8 for patients receiving 25 mg VRS-859 was 56.3 mg.hr/dL and 43.2 mg.hr/dL, respectively. These initial results suggest that 25 mg VRS-859 provides effective glycemic control over a week after dosing without gastrointestinal adverse events (a known side effect of this class of drug).

Conclusion: VRS-859 is well tolerated and provides glycemic control in T2DM patients. Additional results from enrolled dose levels including the anticipated monthly dose (100 mg) will be presented.

Monotherapy with the once-weekly GLP-1 analogue LY2189265 for 12 weeks in patients with type 2 diabetes: dose-dependent effects in a randomised, double-blind, placebo-controlled study

G. Grunberger¹, A. Chang², G. Garcia Soria³, F.T. Botros⁴, R. Bsharat⁴, Z. Milicevic⁵;

¹Grunberger Diabetes Institute, Bloomfield Hills, USA, ²John Muir Physician Network Clinical Research Center, Concord, USA, ³IMIC Research, Mexico City, Mexico, ⁴Lilly Research Laboratories, Indianapolis, USA, ⁵Lilly Research Laboratories, Vienna, Austria.

Background and aims: We evaluated the dose-dependent effects of once-weekly LY2189265 (LY), a glucagon-like peptide-1 (GLP-1) analog, on glycaemic control [hemoglobin A_{1c} (HbA_{1c})] in patients with type 2 diabetes treated with life-style measures.

Materials and methods: This was a double-blind, placebo-controlled study in 164 patients (at entry, mean±SD: age 57±9 years; BMI 32.1±4.8 kg/m²; and HbA_{1c} 7.2±0.6%) who were antihyperglycaemic medication naïve or had discontinued metformin monotherapy. Patients entered a 4 to 8-week lead-in period. Those with qualifying HbA_{1c} values (≥6.5% to ≤9.5%) were randomized (mean baseline HbA_{1c} between 7.6±0.7% and 7.8±0.8%) to once-weekly subcutaneous injections of placebo or LY (0.1 mg, 0.5 mg, 1.0 mg, or 1.5 mg) for 12 weeks, followed by a 4-week safety follow up.

Results: At week 12, statistically significant dose-dependent reductions in HbA_{1c} (LS mean±SE) were observed across LY2189265 doses (p<0.001). HbA_{1c} reductions in LY0.5, LY1.0, and LY1.5 treatment groups were statistically significantly greater than the placebo group (-0.89±0.12%, -1.03±0.11%, and -1.04±0.13% vs. 0.01±0.13%, respectively, all p<0.001, Figure 1). Dose-dependent reductions were also observed in fasting plasma glucose (ranging from -2.08±0.27 mmol/L in LY1.5 mg to -0.21±0.25 mmol/L in placebo group, p<0.001). Percent of patients achieving HbA_{1c} <7.0% in all groups at the 12 week endpoint were: placebo (21%), LY0.1 (47%), LY0.5 (73%), LY1.0 (75%), and LY1.5 (71%). A significant dose-dependent weight loss was demonstrated across LY2189265 doses (p=0.009), but none of the groups were different from the placebo group. Significant dose-dependent increases in homeostatic model assessment (HOMA2%B) were observed across LY groups (p=0.036) indicating improvement of beta cell function. Increases were significantly larger in each of the LY doses compared to placebo (p≤0.013) except the LY0.1 group (p=0.325). Overall, the most common adverse events were nausea 7.9% (n=13), diarrhea 6.1% (n=10), and nasopharyngitis 5.5% (n=9).

Conclusion: Treatment of patients with type 2 diabetes for 12 weeks with the long-acting GLP-1 analog LY2189265 as monotherapy resulted in dose-dependent reductions in HbA_{1c} and blood glucose with an acceptable safety profile of all doses.

Improved patient satisfaction with ITCA 650 vs. exenatide injections in subjects with metformin-treated type 2 diabetesT. Alessi¹, R.R. Henry², J. Rosenstock³, K. Luskey¹;¹Intarcia Therapeutics, Hayward, ²University of California at San Diego, La Jolla, ³Dallas Diabetes and Endocrine Center, Dallas, USA.

Background and aims: The relationship between exenatide treatment and patient satisfaction was examined in a study evaluating ITCA 650, a subcutaneous osmotic delivery system that provides for the continuous delivery of exenatide at specified doses for 3 months, and twice-daily exenatide injections.

Materials and methods: A 24-week phase 2 study was conducted in which patients were randomized to one of two doses of ITCA 650 (20 and 40 mcg/day) or exenatide injections (5 mcg BID x 4 weeks, 10 mcg BID x 8 weeks) administered for the first 12 weeks. In the second 12 weeks, subjects receiving exenatide injections were switched to ITCA 650 (40 and 60 mcg/day) and subjects receiving ITCA 650 were randomly assigned to either continue their previous dose or the dose was escalated to 60 or 80 mcg/day. The Diabetes Medications Satisfaction Tool (DM-SAT) was administered prior to initial treatment and at week 8 and week 20 of treatment. This questionnaire consists of 16 questions and evaluates overall satisfaction as well as satisfaction grouped into four subscales: lifestyle, well-being, glucose control and convenience.

Results: As indicated in the table, reductions in HbA_{1c} and weight were seen at week 12 in all groups and at week 8 the increase in overall satisfaction with treatment was greater among patients treated with either 20 or 40 mcg/d of ITCA 650 than with exenatide injections (25% and 40% vs.15%). A similar pattern was observed for the subscale scores where increased satisfaction with either dose of ITCA 650 was greater than the change with exenatide injections. At week 20, further improvements in HbA_{1c} and weight were seen with dose escalation and treatment satisfaction was maintained after the 2 - 3 fold dose escalation of ITCA 650. The most impressive results were observed among patients who started on exenatide injections and then switched to ITCA 650 where an average improvement of 20% in overall score was observed between week 8 (on exenatide injections for 8 weeks) and week 20 (on ITCA 650 for 8 weeks). GI side effects did not appear to impact the satisfaction score as an increase was also seen in subjects who reported nausea, similar to those that did not report nausea.

Conclusion: This study indicates that exenatide treatment was associated with an increase in patient satisfaction; however, the improvement was substantially greater with ITCA 650 compared to twice-daily injections. The ability to deliver exenatide in an injection-free manner that does not require any intervention by the patient ensures consistent compliance with prescribed treatment and results in increased satisfaction that may ultimately lead to improved persistence on long-term exenatide therapy. Evaluation of 6- to 12-month devices will be undertaken in phase 3 studies and may further enhance patient satisfaction.

in reducing FPG, HbA_{1c} and body weight (BW). The relationship between the PK and PD of ITCA 650 was examined.

Materials and methods: PK (plasma exenatide concentrations) and PD (FPG, HbA_{1c}, BW) data were collected from type 2 diabetics in a 28-day Phase 1b study (44 subjects) and a 24-week Phase 2 study (155 metformin-treated subjects) with a 24-week extension period. ITCA 650 doses ranged from 10-80 mcg/day in Phase 1b and 20-80 mcg/day in Phase 2. C_{ss} and AUC_{ss} were assessed from 24 hrs after device insertion through end of treatment. Exposure-response relationships were assessed with linear and tobit regression models, and graphically explored with LOESS (locally weighted scatterplot smoothing) techniques.

Results: There was a dose-proportional increase in exenatide exposure (AUC_{ss} and C_{ss}). Mean C_{ss} ranged from 38 ± 12 pg/mL at 10 mcg/day to 290 ± 117 pg/mL at 80 mcg/day. ITCA 650 provided continuous exposure for the duration of each device insertion (up to 12 weeks) and for the duration of treatment (up to 48 weeks). Exposures with ITCA 650 were consistent with exposures reported for SC infusion and BID exenatide injection. In contrast to BID exenatide injections, a pattern of peak and trough levels was not observed with ITCA 650. The effects of ITCA 650 were apparent within 24 hrs of device insertion. Plasma exenatide was detected in 32 of 44 Phase 1 subjects within 6-12 hrs, and steady state concentrations were achieved within 24 hrs in all dose groups. Reductions in FPG were observed within one day. FPG and 2-hr postprandial glucose were significantly decreased in the 20, 40 and 80 mcg/day dose groups within 1-5 days of initiating ITCA 650 and throughout the 28-day treatment period (p<0.05). The PK/PD relationship of exenatide exposure relative to changes in HbA_{1c} and BW was examined in Phase 2. All doses (20-80 mcg/day) were active suggesting an ED₅₀ of < 20 mcg/day. Higher exenatide concentrations tended to produce larger reductions in HbA_{1c} and BW; concentrations associated with all doses were on the relatively flat upper part of the response curve. These PD responses were maintained over 48 weeks of treatment. Baseline HbA_{1c} also contributed to the change in HbA_{1c}. In the combined population from all dose groups, subjects in the lowest quartile of starting HbA_{1c} values had a mean HbA_{1c} of 7.0% and a change in HbA_{1c} of -0.7% whereas subjects in the highest quartile had a HbA_{1c} of 9.2% and a mean change in HbA_{1c} of -1.9%. Consistent with its 2.4 hr half-life, exenatide was not measurable in any subject 24 hrs after ITCA 650 device removal. Samples collected at the next visit 7 days later confirmed that FPG levels had returned to baseline values.

Conclusion: ITCA 650 provides continuous exposure to exenatide for the duration of device insertion, dose-proportional exposures, rapid attainment of steady state plasma exenatide following device insertion and rapid clearance of exenatide after device removal. A relationship between exenatide exposure and glycemic and weight parameters was noted. In addition, the baseline HbA_{1c} played a role in the magnitude of the response to ITCA 650 treatment.

Pharmacokinetic and pharmacodynamic assessments with ITCA 650, a continuous subcutaneous delivery of exenatide via DUROS[®] device, in type 2 diabetesJ. Dahms¹, Y. Chandrasekher¹, R. Fielding², R. Zhou³, R.R. Henry⁴, J. Rosenstock⁵, T. Alessi¹, K. Luskey¹;¹Intarcia Therapeutics, Hayward, ²Biologistic Services, Boulder, ³Medpace, Cincinnati, ⁴University of California at San Diego, La Jolla, ⁵Dallas Diabetes and Endocrine Center, Dallas, USA.

Background and aims: ITCA 650 is a subcutaneous osmotic delivery system that provides for the continuous delivery of exenatide. ITCA 650 is effective

PS 064 Liraglutide: clinical studies and observations

791

The impact of disease stage, indicated by number of previous oral antidiabetic agents, on the clinical benefits of liraglutide in the treatment of type 2 diabetes

A. Garber¹, D. Matthews², B. Zinman³, A.B. Thomsen⁴, A. Falahati⁴, B. Guerci⁵

¹Baylor College of Medicine, Houston, USA, ²OCDEM, Oxford, UK, ³Mt Sinai Hospital, Toronto, Canada, ⁴Novo Nordisk A/S, Copenhagen, Denmark, ⁵University of Nancy I and Center of Clinical Investigation-INSERM, France.

Background and aims: The optimal point for GLP-1 receptor agonist therapy of type 2 diabetes is unclear. This analysis seeks to determine efficacy differences between early liraglutide addition (add-on to patients on ≤ 1 oral antidiabetic agent [OAD]) vs later liraglutide addition (add-on to ≥ 2 OADs) in patients with T2D.

Materials and methods: To evaluate the effect of placebo or liraglutide (1.2 mg or 1.8 mg), a pooled analysis of 26-week data from 7 randomised phase 3a and 3b clinical trials (n=4625) was carried out. Patients continued pre-trial OAD treatment throughout the trial; analyses were stratified according to pre-trial treatment status: diet/exercise or add-on to one OAD (Early), vs add-on to ≥ 2 OADs (Late). Beta-cell function was assessed by HOMA-B and proinsulin:insulin ratio.

Results: The mean duration of diagnosed diabetes was 6 years in the early group and 9 years in the late addition group. Change in HbA_{1c} from baseline was significantly greater in all early vs late patient treatment cohorts; for patients receiving liraglutide 1.8 mg, treatment difference (95% confidence interval [CI]): -0.36 [-0.52, -0.20]; $p < 0.0001$ (Table). A similar trend was observed in patients receiving liraglutide 1.2 mg and placebo. A significantly higher proportion of patients receiving liraglutide 1.8 mg early reached HbA_{1c} target $< 7\%$ than those treated late (Table). There was a significantly greater improvement in HOMA-B among patients treated early vs late with liraglutide 1.8 mg (Table). These differences persisted after correction for differences in baseline HbA_{1c}, weight and other parameters.

Conclusion: Liraglutide administration to patients who were treatment naive or previously receiving only 1 OAD produced greater glycaemic efficacy than in patients taking 2 or more OADs. This analysis suggests that use of liraglutide early in type 2 diabetes may provide greater clinical benefit and potential improvement in beta-cell function as compared with liraglutide treatment later in the disease process.

After one year of treatment, liraglutide more successfully reduces HbA_{1c} than sitagliptin across a broad range of baseline HbA_{1c} values, when both are combined with metformin

M. Davies¹, R. Pratley², E. Montanya Mias³, Y. Xu⁴, H. Hartvig⁵, G. Sesti⁶

¹University Hospitals of Leicester, UK, ²University of Vermont College of Medicine, Burlington, USA, ³IDIBELL-Hospital Universitari Bellvitge, Barcelona, Spain, ⁴Novo Nordisk Inc, Princeton, USA, ⁵Novo Nordisk A/S, Copenhagen, Denmark, ⁶University Magna Graecia of Catanzaro, Italy.

Background and aims: Baseline HbA_{1c} is an important factor in therapy choice and also influences the magnitude of response to diabetes treatment. The aim of this study was to perform a post-hoc analysis to determine the impact of baseline HbA_{1c} on final HbA_{1c} following liraglutide or sitagliptin treatment in patients with type 2 diabetes.

Materials and methods: A 26-week randomised trial previously demonstrated that in comparison with sitagliptin 100 mg/day (SITA), liraglutide (LIRA) once daily (1.2 mg and 1.8 mg) produced greater reductions in HbA_{1c} from baseline. Furthermore, a post-hoc analysis showed that at the highest ($> 9.0\%$) and lowest ($< 8.0\%$) baseline HbA_{1c} values, both doses of LIRA were more effective at lowering HbA_{1c} than SITA. We report a similar post-hoc analysis following a 26-week extension of this randomised trial, in which patients continued treatment to which they were originally randomised. Five baseline HbA_{1c} ranges were used to categorise patients (see Figure).

Results: Over 52 weeks, LIRA (both 1.2 and 1.8 mg) and SITA improved glycaemic control across all baseline HbA_{1c} categories, with the greatest reductions observed at higher baseline HbA_{1c} levels (LS means from ANCOVA). Reductions in HbA_{1c} across baseline categories ranged from 0.3–1.3% for SITA, 0.4–1.8% for LIRA 1.2 mg, and 0.9–1.9% for LIRA 1.8 mg. End of treatment HbA_{1c} ranged from 7.1–8.2% for SITA, 6.9–7.8% for LIRA 1.2 mg, and 6.4–7.6% for LIRA 1.8 mg. LIRA 1.8 mg reduced HbA_{1c} significantly more vs. SITA in all baseline HbA_{1c} categories: ($p < 0.05$), while LIRA 1.2 mg reduced HbA_{1c} significantly vs. SITA in two baseline categories: > 8.0 – $\leq 8.5\%$ ($p = 0.005$) and $> 9.0\%$ ($p = 0.03$). There were no significant differences between LIRA 1.2 mg and LIRA 1.8 mg in any baseline HbA_{1c} category. Nausea was higher with LIRA (1.2 mg, 21.7%; 1.8 mg, 27.5%) than SITA (5.5%), but the incidence declined and rates were similar at 52 weeks. Minor hypoglycaemia (episodes/patient/year) was similar for LIRA 1.2 mg (0.143), 1.8 mg (0.154) and SITA (0.137).

Conclusion: Across a broad range of baseline HbA_{1c} values including at HbA_{1c} levels of $< 7.5\%$, LIRA more successfully reduced HbA_{1c} than SITA, over 1 year's treatment in combination with metformin.

Liraglutide achieved greater weight reduction and improved glycaemic control compared with sitagliptin following one-year treatment when both are used in combination with metformin

D.R. Matthews¹, G. Sesti², R. Pratley³, L. Grimmshave⁴, Y. Xu⁵, A. Garber⁶; ¹Oxford Centre for Diabetes, Endocrinology & Metabolism, The Churchill Hospital, Oxford, UK, ²University Magna Graecia of Catanzaro, Italy, ³University of Vermont College of Medicine, Burlington, USA, ⁴Novo Nordisk A/S, Copenhagen, Denmark, ⁵Novo Nordisk Inc, Princeton, USA, ⁶Baylor College of Medicine, Houston, USA.

Background and aims: Glucagon-like peptide-1 (GLP-1) receptor agonists are associated with weight loss in many patients while DPP-4 inhibitors have typically been shown to be weight-neutral. The results from a 26-week randomised head-to-head comparison study, liraglutide 1.2 mg and 1.8 mg once daily resulted in significant HbA_{1c} reduction and weight loss as compared to sitagliptin, both in combination with metformin. We report the results from the comparable post-hoc analysis following a 26-week extension of this randomised trial.

Materials and methods: During the trial extension, patients continued treatment to which they were originally randomised. 497/554 (90%) of completers from the initial 26-week study entered the 26-week extension phase. The effect of weight reduction category on HbA_{1c} was analysed using a post-hoc ANCOVA conducted on data from the full analysis set with last observation carried forward (LOCF).

Results: After 1 year's treatment, weight reductions in the total study population were significantly greater for LIRA 1.2 mg and 1.8 mg than SITA (-2.8 kg and -3.7 kg, vs -1.2 kg, respectively; $p=0.0001$). Patients who lost >3% BW had significantly greater reductions in HbA_{1c} compared with those who lost ≤3% BW in all treatment groups (Fig). Within each weight-loss group, treatment with LIRA 1.8 mg led to significantly greater reduction in HbA_{1c} vs SITA, and in the ≤3% weight-loss group LIRA 1.2 mg led to a significant reduction in HbA_{1c} vs SITA. The proportion of patients achieving the ADA target HbA_{1c} <7.0% was significantly greater with LIRA 1.8 mg in both groups vs. SITA and for 1.2 mg in the ≤3% group vs SITA.

Conclusion: One year of liraglutide treatment resulted in significantly higher proportion of patients achieving substantial weight loss than sitagliptin. HbA_{1c} reduction is significantly greater in patients with >3% weight loss with either treatment. HbA_{1c} reductions were significantly greater with LIRA 1.8 mg compared with SITA regardless of the level of weight loss achieved.

% represents proportion of patients in each treatment group in that weight loss category. Change in HbA_{1c} was significantly greater in WL ≤ 3% compared to WL > 3% for each treatment.

Liraglutide produces greater reductions in HbA_{1c} levels compared with sitagliptin or exenatide across five baseline HbA_{1c} categories

T. Bailey¹, R. Pratley², J. Buse³, S. Furber⁴, H. Hartvig⁴, W.E. Schmidt⁵; ¹AMCR Institute, Escondido, USA, ²University of Vermont College of Medicine, Burlington, USA, ³University of North Carolina School of Medicine, Chapel Hill, USA, ⁴Novo Nordisk A/S, Copenhagen, Denmark, ⁵Ruhr-University of Bochum School of Medicine, Germany.

Background and aims: Patients with higher baseline HbA_{1c} values demonstrate a greater reduction in absolute HbA_{1c} levels when treated with several type 2 diabetes therapies. When selecting therapeutic regimens for patients, physicians indicate that the availability of treatment comparisons can provide an invaluable resource to ensure that the most appropriate therapy is prescribed. We performed a meta-analytical assessment of patient level data of three incretin-based therapies in order to determine the effect of these therapies on HbA_{1c} levels based upon baseline HbA_{1c}.

Materials and methods: This meta-analysis comprised two phase 3 trials, one comparing liraglutide 1.8 mg once-daily with exenatide 10 µg twice-daily (both plus metformin [met] and/or sulphonylurea) and the other comparing liraglutide 1.8 mg (+met) with sitagliptin 100 mg (+met). Patients were allocated to five baseline HbA_{1c} categories: ≤7.5%, 7.5–8.0%, 8.0–8.5%, 8.5–9.0%, >9.0%. ANCOVA analysis (last observation carried forward, intention to treat population) was employed to estimate HbA_{1c} changes from baseline to 26 weeks, with respect to baseline HbA_{1c}. Country and interaction between treatment and HbA_{1c} category were included as fixed effects.

Results: HbA_{1c} improvements were observed for all treatments and across every HbA_{1c} category. Greater reductions were observed in higher baseline HbA_{1c} categories (figure). In the lowest baseline HbA_{1c} category (≤7.5%) reductions from baseline were 0.8% (liraglutide), 0.6% (exenatide) and 0.05% (sitagliptin), whereas greater reductions were observed in the highest baseline HbA_{1c} category (>9.0%), 2.1%, 1.5% and 1.2% respectively. Significantly greater reductions in HbA_{1c} were seen with liraglutide vs. sitagliptin across all HbA_{1c} categories. Liraglutide offered greater HbA_{1c} reductions vs. exenatide in all HbA_{1c} groups, with statistical significance being achieved in the 7.5–8.0% and >9.0% categories.

Conclusion: Reductions in HbA_{1c} were observed in all categories regardless of treatment, with greater reductions being observed in categories with higher baseline HbA_{1c} levels. Liraglutide offered significantly greater HbA_{1c} improvements compared with sitagliptin across every HbA_{1c} category and in all HbA_{1c} categories when compared with exenatide, two of which reached statistical significance.

Greater glycaemic control is achieved with the once-daily human GLP-1 analogue liraglutide vs comparators across the continuum of estimated beta cell mass

J.J. Meier¹, T. Vilsbøll², M. Donsmark³, H. Hartvig³, M.A. Nauck⁴;

¹St. Josef Hospital, Bochum, Germany, ²Gentofte Hospital, Copenhagen, Denmark, ³Novo Nordisk A/S, Copenhagen, Denmark, ⁴Diabeteszentrum, Bad Lauterberg im Harz, Germany.

Background and aims: Glycemic control is closely related to pancreatic β -cell mass in humans. A recent study showed that in patients with and without T2D, a C-peptide:fasting plasma glucose (FPG) ratio appears to be a better predictor of pancreatic β -cell area (as an estimate of β -cell mass) than measures such as the Homeostasis Model Assessment (HOMA) index. This analysis investigated the glycemic efficacy of the once-daily (OD) human glucagon-like peptide (GLP)-1 analog liraglutide (LIRA) vs other antidiabetic agents in patients with T2D as a function of estimated residual β -cell mass.

Materials and methods: A meta-analysis of patient level data was performed across 7 randomised phase 3 trials from the liraglutide development program, using data from 0–26 weeks. An ANCOVA model adjusted by quartile of residual β -cell mass (defined by C-peptide:FPG ratio) at baseline, was used to assess change in HbA_{1c} from baseline ($n=3941$) with LIRA 1.8 and 1.2 mg OD vs exenatide (EXEN), sitagliptin (SITA), sulfonylurea (SU), thiazolidinedione (TZD) or placebo in patients with T2D. A logistic regression model was used to assess percentage of patients achieving target $HbA_{1c} < 7\%$ by quartile of residual β -cell mass ($n=1577$) vs comparators. ANCOVA and the logistic regression model used trial, previous treatment and interaction between treatment and baseline C-peptide:FPG quartile as fixed effects and baseline HbA_{1c} as covariate.

Results: After 26 weeks' treatment with LIRA 1.8 mg, HbA_{1c} reduction from baseline and number of patients reaching target $HbA_{1c} < 7\%$ were significantly greater in all quartiles of estimated β -cell mass compared with sitagliptin, TZD or placebo (Fig). In patients with the greatest estimated β -cell mass at baseline (Quartile 4; Q4), both HbA_{1c} reduction and patients reaching target with liraglutide 1.8 mg (69.8%) were significantly greater at 26 weeks vs EXEN (49.7%), SU (49.8%), TZD (41.0%), SITA (21.3%) and placebo (21.7%). HbA_{1c} reduction and patients reaching target with LIRA 1.2 mg (61.3%) in Q4 were significantly greater than with SITA and placebo. In Q2 and Q3, the trend was towards greater HbA_{1c} reduction and a greater percentage of patients reaching target with both LIRA 1.2 and 1.8 mg vs comparators. In patients with the lowest estimated β -cell mass at baseline (Q1), HbA_{1c} reduction and patients reaching target were similar between LIRA, SU and EXEN. However, HbA_{1c} reduction and patients reaching target in Q1 were significantly greater with LIRA 1.8 mg (57.3%) vs SITA (20.6%), TZD (29.5%) and placebo (14.9%).

Conclusion: These data demonstrate that in patients with T2D, glycemic control with liraglutide is effective across the continuum of estimated β -cell mass. In particular, this finding implies enhanced glycemic benefits with liraglutide vs comparators, in patients at early and later stages of T2D disease progression.

In patients with type 2 diabetes, overall treatment satisfaction improves following a switch from sitagliptin to liraglutide treatment in combination with metformin

E. Montanya Mias¹, R. Pratley², M.A. Nauck³, T. Bailey⁴, A. Garber⁵, S. Filetti⁶, A.B. Thomsen⁷, M. Hammer⁷, M. Davies⁸;

¹Hospital Universitari Bellvitge-IDIBELL, Barcelona, Spain, ²University of Vermont College of Medicine, Burlington, USA, ³Diabeteszentrum Bad Lauterberg, Germany, ⁴AMCR Institute, Escondido, USA, ⁵Baylor College of Medicine, Houston, USA, ⁶La Sapienza University of Rome, Italy, ⁷Novo Nordisk A/S, Copenhagen, Denmark, ⁸University of Leicester, UK.

Background and aims: Patient-reported outcomes (PRO) from clinical trials provide insight into how treatments meet patients' needs and expectations. It has previously been shown that 1-year treatment with liraglutide (LIRA) 1.2 mg or 1.8 mg OD led to superior glycaemic control and weight loss vs sitagliptin (SITA) 100 mg OD, both added to metformin (MET) ≥ 1500 mg. During a 26-week extension period, patients treated with SITA randomly switched to LIRA 1.2 or 1.8 mg, resulting in further HbA_{1c} reductions and weight loss (HbA_{1c} : -0.24%, -0.45%; weight: -1.6 kg, -2.5 kg for SITA→LIRA 1.2 and 1.8 mg, respectively). Here we report PRO results from a pre-defined sub-population of this trial.

Materials and methods: Treatment satisfaction (TS) was evaluated using the Diabetes Treatment Satisfaction Questionnaire (DTSQ) at 52 and 78 weeks to assess the impact of switching from an oral therapy to an injectable one. Overall TS was calculated by adding satisfaction scores for 'current treatment', 'convenience', 'flexibility', 'understanding', 'recommend', and 'continue'. Higher scores indicated improved TS. For evaluation of perceived frequency of hyper- and hypoglycaemia, lower scores indicate improvement. Changes in TS scores were analysed by paired *t*-test.

Results: In total, 102 subjects were included in this PRO analysis (SITA→LIRA 1.2 mg, $n=54$; SITA→LIRA 1.8 mg, $n=48$). Overall TS improved in both groups of patients who switched from SITA to LIRA (SITA→LIRA 1.2 mg, 1.48 [$p=0.0170$]; SITA→LIRA 1.8 mg, 0.98 [$p=NS$]; Figure) and was driven largely by the categories 'recommend' (SITA→LIRA 1.2 mg, 0.39 [$p=0.0025$]; SITA→LIRA 1.8 mg, 0.12 [$p=NS$]; Figure) and 'continue' present treatment (SITA→LIRA 1.2 mg, 0.56 [$p=0.0099$]; SITA→LIRA 1.8 mg, 0.06 [$p=NS$]; Figure); no statistical difference was observed between LIRA 1.2 mg and 1.8 mg after the switch. Significant reductions in 'perceived frequency of hyperglycaemia' were observed in both groups (figure). 'Convenience', 'flexibility',

‘understanding’ and ‘perceived hypoglycaemia’ were unchanged after switching from oral to injectable treatment.

Conclusion: Switching from an oral therapy to an injectable did not negatively affect treatment satisfaction; on the contrary patients who switched to LIRA had an increase in overall TS (significant for 1.2 mg). The greater treatment satisfaction with liraglutide may be facilitated by weight loss and the improved treatment efficacy or perception thereof.

Figure: Change in mean TS scores from Week 52 to Week 78 for patients switching from sitagliptin to liraglutide

Parameter	Before Liraglutide (n=9)	After Liraglutide (n=9)	P value
PASI	3.9 (2.6-7.4)	3.0 (0.5-6.0)	0.031
DLQI	4.0 (0.0-6.8)	1.5 (0.0-4.5)	0.023
iNKT (%CD3)	0.19 (0.13-0.29)	0.40 (0.34-0.56)	0.022
Weight (kg)	145 (104-187)	140 (99-177)	0.250
HbA1c (%)	8.3 (6.0-8.6)	7.2 (5.6-7.9)	0.018
HOMA-IR	7.8 (3.7-15.3)	3.9 (1.8-9.5)	0.043

kg, kilogrammes. HOMA-IR, Homeostatic Model of Insulin Resistance. PASI, Psoriasis Area and Severity Index. DLQI, Dermatology Life Quality Index. iNKT, circulating Invariant Natural Killer T cell. %CD3, percentage of T lymphocytes.

Liraglutide decreases psoriasis severity

T. Ahern¹, A.-M. Tobin², M. Corrigan¹, A. Hogan¹, B. Kirby², D. O'Shea¹;

¹Obesity Research Group, ²Dermatology Research Group, St Vincent's University Hospital, Dublin, Ireland.

Background and aims: Gastric bypass surgery leads to an increase in endogenous glucagon-like peptide 1 (GLP-1) levels and can lead to resolution of psoriasis. Invariant natural killer T (iNKT) cells are a rare subset of innate T cells with multiple immunoregulatory properties that are implicated in the pathogenesis of inflammatory disorders. We noted improvement in psoriasis severity in a patient who commenced glucagon-like peptide-1 (GLP-1) analogue therapy to optimise glycaemic control. We have previously found that the number of circulating iNKT cells is low in people with either severe obesity and in people with psoriasis. We have shown that gastric bypass surgery results in an increase in circulating iNKT cell number. We hypothesized that GLP-1 analogue therapy decreases psoriasis severity and increases circulating iNKT cell number.

Materials and methods: Nine people with both diabetes and psoriasis self-administered injections of the GLP-1 analogue, liraglutide, for 8 weeks (0.6mg daily for 2 weeks, then 1.2mg daily). Psoriasis severity was assessed before and 8 weeks after commencing liraglutide therapy using the psoriasis area and severity index (PASI) and the dermatology life quality index (DLQI) questionnaire. The change in circulating iNKT cell number was quantified by flow cytometry. Approval to conduct this study was obtained from the local research ethics committee.

Results: Seven of the participants were male. The median age was 54 years and the median BMI was 46kg/m². Liraglutide therapy led to decreases in the indices of psoriasis severity (PASI and DLQI) and to an increase in circulating iNKT cell number (see table). Weight did not change significantly with liraglutide therapy although HbA1c and the homeostatic model of insulin resistance (HOMA-IR) decreased considerably.

Conclusion: This pilot prospective cohort study suggests that incretin therapy ameliorates psoriasis severity. This effect may be mediated by the improvement in insulin resistance or by the action of GLP-1 on iNKT cells.

Achieving glycaemic control and weight loss with incretin-based therapies: a comparison of liraglutide, exenatide, and sitagliptin

B. Zinman¹, S. Gough², R. Pratley³, J. Brett⁴, N. Lund⁵, J. Buse⁶;¹Mt Sinai Hospital, Toronto, Canada, ²OCDEM, Oxford, UK, ³University of Vermont College of Medicine, Burlington, USA, ⁴Novo Nordisk Inc, Princeton, USA, ⁵Novo Nordisk A/S, Copenhagen, Denmark, ⁶University of North Carolina School of Medicine, Chapel Hill, USA.

Background and aims: Weight gain is a common undesirable outcome associated with several traditional antihyperglycaemic agents used for the treatment of type 2 diabetes. However, incretin-based therapies have been reported to provide enhanced glycaemic control with either weight neutrality (dipeptidyl peptidase-4 inhibitors) or weight loss (glucagon-like peptide-1 receptor agonists).

Materials and methods: We used patient-level data from two large randomised trials to compare the number of patients reaching the composite endpoint of HbA_{1c} levels <7% and weight loss (i.e. weight change <0 kg) after 26 weeks' treatment with liraglutide 1.8 mg or 1.2 mg once daily, exenatide 10 µg twice daily, and sitagliptin 100 mg once daily, all with metformin +/-sulphonylurea as background therapies. A logistic regression analysis with treatment and country as fixed effects and baseline HbA_{1c} and baseline body weight as covariates was performed on an intent-to-treat basis with missing data imputed (last observation carried forward).

Results: Mean baseline HbA_{1c} values were 8.1–8.5%. Reductions in HbA_{1c} from baseline were, in order of decreasing magnitude: liraglutide 1.8 mg (1.3%), liraglutide 1.2 mg (1.1%), exenatide and sitagliptin (both 0.9%). Mean baseline body weights were 93.0–93.8 kg. Reductions from baseline in body weight were, in order of decreasing magnitude: liraglutide 1.8 mg (3.0 kg), liraglutide 1.2 mg (2.7 kg), exenatide (2.3 kg) and sitagliptin (0.8 kg). More patients reached the composite endpoint (HbA_{1c} levels <7% and weight loss) with liraglutide 1.8 mg compared with all the other groups as indicated by the odds ratios and 95% CI: liraglutide 1.2 mg, 1.66 [1.14, 2.41], *p*<0.01; exenatide, 2.10 [1.41, 3.14], *p*<0.001; and sitagliptin 5.70 [3.63, 8.94], *p*<0.001 (Figure).

Conclusion: Patients are more likely to achieve glycaemic control with weight loss on liraglutide 1.8 mg than exenatide or sitagliptin.

p-values are from logistic regression analysis;
p*<0.01 and *p*<0.001 vs liraglutide 1.8 mg

Treatment with exenatide BID and QW for 30 weeks was associated with favourable lipid subclass changes

R. Chilton¹, P. Toth², G. Ramirez³, M. Cobble⁴, B. Walsh⁵, E. Chiquette⁵;¹Univ. of Texas HSC, San Antonio, ²Univ. of Illinois, Peoria, ³Florida International Univ., Miami, ⁴Atherotech, Birmingham, ⁵Amylin Pharmaceuticals, San Diego, USA.

Background and aims: Cardiovascular (CV) disease risk is heavily influenced by metabolic abnormalities, especially dyslipidemia. Lipoprotein subclasses have become increasingly important in the evaluation of intermediate CV risk. Type 2 diabetes mellitus, which continues to increase in prevalence worldwide, is frequently accompanied by atherogenic dyslipidemia that increases risk for CV events. Treatment of type 2 diabetes with the GLP-1 receptor agonist exenatide improves HbA_{1c} as well as body weight, blood pressure, and lipids. This posthoc analysis investigated the effects of exenatide on lipoprotein subclasses.

Materials and methods: Of the 295 ITT patients with type 2 diabetes who participated in DURATION-1, a 30-week, controlled trial of exenatide BID (ExBID) and once-weekly exenatide (ExQW), 211 patients were assessed for lipid subclass changes using the Vertical Auto Profile ultracentrifuge method (n=106 ExQW; n=105 ExBID; 42% female, baseline HbA_{1c}: 8.2±1.0%; baseline weight: 100±19 kg; mean±SD). Baseline to end-of-study lipid changes were initially analyzed as unadjusted change scores using the SPSS General Linear Model, and then by adjusting for changes in HbA_{1c} and body weight.

Results: After 30 weeks of therapy, HbA_{1c} was reduced (LS mean [95%CI]) with ExQW by -1.6% (-1.8, -1.5) and with ExBID by -1.2% (-1.4, -1.1); weight was reduced by -3.9 kg (-4.9, -2.9) with ExQW and by -3.8 kg (-4.8, -2.8) with ExBID. Total cholesterol was not changed with either treatment. HDL and the subclass HDL-2 were significantly improved with ExQW (Table). Of note, HDL-2 was improved after adjustment for change in HbA_{1c} and weight. No change in HDL-3 or ApoA1 occurred with either treatment. LDL was not changed with either treatment; however, ExQW significantly reduced the smaller, denser, atherogenic subclass LDL-4 (even after adjustment for HbA_{1c} and weight change). Furthermore, ExQW significantly reduced ApoB and ApoB/ApoA1 ratio; these improvements remained after adjustment for HbA_{1c} and weight. Both treatments significantly improved triglycerides and VLDL (even after adjustment for HbA_{1c} and weight change). There were no changes in lipoprotein(a), IDL, or non-HDL. Adverse events (ITT population) were primarily gastrointestinal (nausea, vomiting, diarrhea), with a low rate of minor hypoglycaemia (6% incidence) and no major hypoglycaemia.

Conclusion: In this posthoc analysis, ExBID was associated with significant improvements in triglycerides, VLDL and ApoB/ApoA1. ExQW resulted in a more robust lipid improvement, with significant improvements in HDL, HDL-2, LDL-4, triglycerides, VLDL, and ApoB/ApoA1 after 30 weeks of treatment. All of these improvements, except HDL, were statistically significant even after adjustment for changes in weight and HbA_{1c}.

Δ Baseline to Week 30	ExQW	ExQW (adjusted)	ExBID	ExBID (adjusted)

Acute cardiovascular effects of exenatide in healthy male subjectsB. Mendis¹, E.J. Simpson², I.A. Macdonald², P.I. Mansell¹¹Department of Diabetes and Endocrinology, Nottingham University Hospitals NHS Trust, ²School of Biomedical Sciences, University of Nottingham, UK.

Background and aims: In large clinical trials with GLP-1 agonists and mimetics in patients with Type 2 diabetes mellitus (T2DM), a fairly consistent secondary outcome finding is of a moderate but clinically important fall in blood-pressure (ca.5/2mmHg), which precedes any weight loss. Exenatide is also being used to improve cardiac function in patients with left ventricular function and post cardiac surgery. The mechanism underlying the potentially beneficial cardiovascular effects of such drugs is clearly of interest but is not known. In rats, exendin-4, is weakly pressor with a marked increase in the vascular conductance in the hindquarters but vasoconstriction in the mesenteric and, to a lesser extent renal vascular beds. The aim of this study is to assess the acute cardiovascular effects of Exenatide in man.

Materials and methods: We studied 15 healthy non-diabetic, normotensive male subjects aged 18–45 years with BMI 20–27 kg/m² following responses to a single subcutaneous dose of exenatide 10mcg versus placebo. Measurements were made for 2 hours of heart rate (HR), systolic blood pressure (SBP), diastolic blood pressure (DBP), cardiac output (CO) and total peripheral resistance (TPR) by Finometer™. We also measured leg blood flow (LBF) by venous occlusion plethysmography and superior mesenteric artery (SMA) blood flow by Doppler ultrasonography. Arterialised venous blood samples were taken at 15 minute intervals.

Results: Data are given as mean ±SEM. With exenatide compared to placebo there was a greater increase from baseline in HR (change 10.4 ±1.1 beats per minute vs. 2.1 ±1.8 beats per minute, *P*<0.01), CO (change 1.7 ±0.2 l/min vs. 0.5 ± 0.2 l/min, *P*<0.01) and TPR (change -106 ±42.9 dyn.s/cm⁵ vs. 11 ±24.5, *P*< 0.05). There were no significant difference between exenatide and placebo in changes in SBP, DBP, LBF or SMA blood flow, with exenatide, blood glucose fell from 4.5 ±0.1 mmol/l to a nadir of 3.5 ±0.08 mmol/l at 45 minutes and finished at 4.2 ±0.08 mmol/l at 120 minutes.

Conclusion: A single dose of exenatide has significant cardiovascular effects in healthy subjects, in particular with an increase in CO and a decrease in TPR. These findings provide corroborative evidence to support the clinically observed modest hypotensive effect of exenatide in people with T2DM. Further studies are required to understand the mechanisms of the cardiovascular effects of exenatide in more detail.

Comparison of safety with continuous (exenatide once weekly) or intermittent (exenatide twice daily) GLP-1 receptor agonism in patients with type 2 diabetesT. Ridge¹, T. Moretto¹, L. MacConell², R. Pencek², J. Han², C. Schulteis², L. Porter²¹American Health Network, Indianapolis, ²Amylin Pharmaceuticals, Inc., San Diego, USA.

Background and aims: The glucagon-like peptide-1 (GLP-1) receptor agonist exenatide improves glycaemic control and promotes weight loss in patients with type 2 diabetes. Continuous or intermittent GLP-1 receptor agonism is achieved with exenatide once weekly (ExQW) or exenatide twice daily (ExBID), respectively. The objective of this post hoc pooled analysis was to examine safety and tolerability profiles of ExQW vs ExBID in 2 randomized, open-label studies (DURATION-1 and DURATION-5) of 30- or 24-weeks duration. In both studies, ExQW was demonstrated to be statistically superior to ExBID in reducing HbA1c over 30 or 24 weeks, respectively. In the intent-to-treat (ITT) population, least squares (LS) mean changes from baseline in HbA1c were -1.9% (ExQW) and -1.5% (ExBID) in DURATION-1 and -1.6% (ExQW) and -0.9% (ExBID) in DURATION-5, with LS mean treatment differences of 0.33% (DURATION-1) and 0.67% (DURATION-5). In both studies, subjects in both treatment groups lost weight, with LS mean improvements in weight ranging from -1.4 kg to -3.7 kg.

Materials and methods: The studies were conducted in 545 ITT patients (277 ExQW; 268 ExBID) with type 2 diabetes treated with diet/exercise or up to 2 oral antidiabetic medications (baseline [mean ±SD]: HbA1c 8.3 ±1.1%, fasting plasma glucose 9.2 ±2.5 mmol/L, weight 99 ±20 kg). At baseline, patients were drug-naïve (17%) or treated with one (45%) or a combination (38%) of oral

antidiabetes medications. Patients were randomized to receive ExQW (2 mg) or ExBID (5 µg [4 weeks] then 10 µg) over 24 or 30 weeks.

Results: The safety profiles of ExQW and ExBID were generally comparable. The incidence of serious adverse events (AEs; 4% in each group) and AEs leading to withdrawal (5% in each group) was low. The most common AEs were nausea (ExQW 21% vs ExBID 35%), diarrhea (ExQW 12% vs ExBID 9%), injection-site pruritus (ExQW 12% vs ExBID 1%), and vomiting (ExQW 8% vs ExBID 14%). These events were mostly mild/moderate in intensity. More ExBID (4%) than ExQW (1%) patients withdrew due to gastrointestinal AEs. Nausea occurred most frequently upon initiation of ExQW and at initiation and subsequent dose escalation of ExBID. Nausea incidence decreased with ongoing therapy in both groups; in the final 2 weeks of each study, new events of nausea occurred in <1% ExQW and <2% ExBID patients. Vomiting similarly decreased in incidence over time; in the final 2 weeks of each study, new events of vomiting occurred in <2% ExQW and <1% ExBID patients. Mild to moderate injection-site related AEs were more common with ExQW and generally occurred early (no new events after week 14). Two ExQW patients withdrew due to injection-site related AEs. No major hypoglycaemia occurred; minor hypoglycaemia occurred primarily in patients using a sulphonylurea (ExQW 13% vs ExBID 14%) and occurred at low incidence in patients not using a sulphonylurea (ExQW 0% vs ExBID <1%), with no difference between groups and no temporal association with initiation/dose escalation. There was no evidence of prolonged AE duration with ExQW vs ExBID.

Conclusion: Overall, continuous (ExQW) vs intermittent (ExBID) exenatide exposure did not impact the general safety profile of exenatide and both therapies were well tolerated. Less nausea and vomiting was observed with ExQW compared with ExBID. Injection-site related AEs were more frequent with ExQW, but rarely led to withdrawal (<1%).

Clinical Trial Registration Number: NCT00308139, NCT00877890

Exenatide once weekly did not affect the QTc interval in patients with type 2 diabetesP. Sager¹, B. Darpo², J. Han³, B. Cirincione³, H. Linnebjerg⁴, M. Mitchell⁴, L. Porter³¹Sager Consulting Partners, San Francisco, USA, ²Dept. of Clinical Science and Education, Section of Cardiology, Stockholm, Sweden, ³Amylin Pharmaceuticals, Inc., San Diego, USA, ⁴Eli Lilly and Company, Indianapolis, USA.

Background and aims: Exenatide once weekly (QW) is a GLP-1 receptor agonist under development for treatment of type 2 diabetes. The objective of this analysis was to evaluate cardiac repolarization in patients with type 2 diabetes treated with exenatide QW in a Phase 3 study.

Materials and methods: This analysis included 148 patients with type 2 diabetes (mean duration: 7 years) enrolled in the DURATION-1 Phase 3, randomized, open-label, comparator-controlled trial who were treated with exenatide QW (2 mg). Electrocardiograms (ECG) were recorded in triplicate and a concomitant blood sample was collected for exenatide concentration at baseline (prior to study treatment), week 14 (steady-state achieved), and week 30 or early termination. Blinded ECG overread by a cardiologist was performed at an independent core laboratory. The relationship between the Fridericia corrected QT (QTcF) and RR was examined to evaluate the adequacy of QTcF to minimize the confounding effect of heart rate. Consistent with Phase 3 studies, a pharmacological positive control for QT assessment was not included in the trial design; however, a sensitivity analysis of the established negative relationship between fasting plasma glucose (FPG) and change in QTcF (Δ QTcF) was performed to examine the ability to detect a small change in QTcF in this study. Mixed-model repeated measures method was applied to analyze the linear relationship.

Results: After 30 weeks of exenatide QW treatment, HbA1c was reduced by -1.9 ±0.1% (LS mean ±SEM). A small increase in heart rate (mean change [2-sided 90% CI]) was observed at 14 weeks (3.6 bpm [2.3, 4.8]; n=135) and 30 weeks (3.5 bpm [1.9, 5.0]; n=82). A shallow and statistically non-significant QTc/RR slope (*P*-value=0.08; slope: 0.0103) confirmed that the heart rate change was appropriately corrected by QTcF. A statistically significant negative relationship between FPG and Δ QTcF was detected (*P*-value=0.04; slope [95% CI]: -0.0526 [-0.1036, -0.0016]), indicating that the study was sufficiently sensitive to detect small changes in QTcF. The Δ QTcF (mean change [2-sided 90% CI]) was small and clinically insignificant at 14 weeks (1.7 ms [0.3, 3.1]) and 30 weeks (3.0 ms [0.9, 5.1]). No patient had a QTcF interval during treatment that exceeded 450 ms or a Δ QTcF >60 ms; 3 patients had a Δ QTcF >30 ms (30, 33, and 39 ms). The Δ QTcF was not accentuated in pa-

tients with the highest exenatide concentrations or renal insufficiency ($n=55$). Concentration-QTc analysis did not demonstrate a correlation between exenatide concentration and Δ QTcF (Figure).

Conclusion: In this study, exenatide once weekly treatment did not affect cardiac repolarization, measured by the QTcF interval, in patients with type 2 diabetes.

Clinical Trial Registration Number: NCT00308139

803

The risk of heart failure among patients receiving exenatide twice daily versus other glucose-lowering medications for diabetes: a matched retrospective analysis of the GE Healthcare EMR data

J.H. Best¹, D. Maggs¹, W. Little², E. Chiquette¹, W.B. Saunders³;

¹Amylin Pharmaceuticals, Inc., San Diego, USA, ²Wake Forest University, Winston-Salem, USA, ³GE Healthcare, Charlotte, USA.

Background and aims: Exenatide twice daily (ExBID), a glucagon-like peptide-1 (GLP-1) receptor agonist, has demonstrated improvements in cardiovascular risk factors in patients with diabetes. We hypothesized that the addition of ExBID to other glucose-lowering therapies may reduce the risk of developing heart failure, defined as diagnosis of ICD-9 code 428 or brain natriuretic peptide >100 pg/mL. This retrospective matched cohort study used data obtained from the national Medical Quality Improvement Consortium of ambulatory medical practices (>14,000 providers) that use Centricity Office from GE Healthcare IT as their electronic medical record.

Materials and methods: Patients with diabetes receiving a prescription for glucose-lowering therapy (ExBID, insulin [INS], and/or other [OTH, excluding ExBID and INS]) between 1 Jan 2005 and 30 Sept 2010 were identified ($n = 778,408$). Therapies may have been prescribed serially or concomitantly. Patients using ExBID were randomly matched 1:1 to patients not receiving ExBID based on gender, 10 year age band, follow-up time, and any use of thiazolidinediones. Odds ratios (OR) were calculated using conditional logistic regression models with and without adjustment for weighted Charlson Comorbidity Index (CCI), a disease severity measure.

Results: Without adjustment for CCI, the rate of heart failure (affected/total) among patients that received ExBID+INS+OTH was 4.15 vs 8.88 for INS+OTH (OR = 0.41; 95% CI = 0.33-0.50). The rate of heart failure among patients that received ExBID+OTH was 1.54 vs 2.34 in matched controls (OR = 0.66; 95% CI = 0.58-0.75). After adjustment for CCI, risk of heart failure for patients who received ExBID+INS+OTH was 57% lower vs INS+OTH (OR = 0.43; 95% CI = 0.40-0.47; $n = 48,184$). With adjustment for CCI, the risk of heart failure for patients who received ExBID+OTH was 38% lower vs OTH (OR = 0.62; 95% CI = 0.54-0.70; $n = 53,354$). Finally, in a model adjusting for CCI that included all patients that received ExBID vs all non-ExBID controls, the risk of heart failure was 51% lower (OR = 0.49; 95% CI = 0.46-0.52; $n = 101,538$).

Conclusion: In this analysis the addition of ExBID to glucose-lowering regimens for the treatment of diabetes was associated with reduced risk of developing heart failure.

804

The Association of British Clinical Diabetologists (ABCD) nationwide exenatide and liraglutide audits

R.E.J. Ryder, K.Y. Thong, M.L. Cull, A.P. Mills, C. Walton, ABCD nationwide exenatide and liraglutide audit contributors;
Diabetes, Endocrinology and Lipids Metabolism, City Hospital, Birmingham, UK.

Background and aims: To compare use and efficacy of exenatide and liraglutide in two large scale nationwide audits of real clinical practice.

Materials and methods: Exenatide/liraglutide audits respectively: 128/64 centres across UK submitted anonymised data on 6717/3010 patients during 2007-2009/2009-2010. Previous exenatide users were excluded from liraglutide analysis leaving 2303 patients.

Results: Baseline characteristics of patients are shown in Table 1. All data expressed as exenatide/liraglutide. At 6 months, mean (SE) HbA1c reduction were 0.75(0.04) v 0.93(0.07)% (difference, $p=0.040$) among 3166 patients. Weight reduction were 6.5(0.1) v 3.7(0.2) kg (difference, $p<0.001$) among 2790 patients. All HbA1c and weight changes from baseline were significant ($p<0.001$). Exenatide/liraglutide data for cholesterol reduction were 0.16(0.03)/0.14(0.05) mmol/L, triglycerides reduction were 0.14(0.06)/0.26(0.10) mmol/L and systolic blood pressure reduction were 3.6(0.6)/4.6(0.9) mmHg. These were significant from baseline (at least $p<0.05$). There was no change in diastolic blood pressure in the exenatide audit but with liraglutide this fell by 1.2(0.5) mmHg ($p=0.023$). Baseline treatment use(discontinuation) was sulphonylurea 49.5/42.8(6.5/5.3)%, thiazolidinedione 27.1/20.5(13.4/7.5)%, DPP4 inhibitor 2.2/10.9(1.4/9.3)%, insulin 33.9/39(8.1/2.6)%.

Conclusion: These very large audits reveal the effectiveness of these agents in much heavier and more poorly controlled patients than those studied in clinical trials. Patients achieved greater HbA1c reduction but lesser weight reduction in the liraglutide audit as compared with the exenatide audit. However, there were lesser insulin and TZD discontinuation but greater DPP4 inhibitor discontinuation in the liraglutide audit. Contributors might have learnt from the previous use of exenatide to avoid over-reduction of diabetes treatment when initiating liraglutide

	Exenatide	Liraglutide	p-value
n	6717	2303	
Male (%)	54.9	54.1	0.491
Caucasian (%)	84.4	90.4	<0.001

Factors associated with HbA_{1c} and weight changes at 6 months in the Association of British Clinical Diabetologists (ABCD) nationwide exenatide and liraglutide audit

C. Walton¹, R.E.J. Ryder², M.L. Cull², A.P. Mills², K.Y. Thong²;

¹Diabetes, Hull Royal Infirmary, ²Diabetes, City Hospital, Birmingham, UK.

Background and aims: Treatment with GLP-1 agonists in type 2 diabetes has the advantage of weight loss but they are not effective in every patient. Factors that help predict response to treatment is needed. ABCD conducted two nationwide audits on exenatide and liraglutide based on real clinical practice.

Materials and methods: Patients from both audits were pooled together for analyses. Univariate followed by multivariate analyses were performed to assess for factors that were associated with HbA1c and weight change after GLP-1 agonist treatment. Latest HbA1c and weight changes by 6 months were used as continuous response variables and were assessed against other continuous variables of baseline HbA1c, weight, weight or HbA1c change, patient age, diabetes duration, total insulin dose (logarithm-transformed) and insulin dose reduction. Categorical variables assessed were gender, ethnicity (Caucasian/South Asian/Afro-Caribbean), oral hypoglycaemic agent change (stopped or reduced/unchanged/started or increased) and insulin use (yes/no). To avoid limiting the multivariate analyses to only insulin patients, two models were assessed each for HbA1c and weight change, the first with all significant univariate variables and with the variable insulin use, the second with total insulin dose and insulin dose reduction.

Results: 9020 patients with 5407 and 5245 follow-up HbA1c and weight results were analysed. Univariate analyses showed HbA1c reduction being correlated with higher baseline HbA1c and inversely with baseline weight, weight reduction, diabetes duration, TZD reduction, insulin use, higher insulin dose reduction (all $p < 0.001$) and higher daily insulin dose ($p = 0.012$). Univariate analyses for weight reduction showed correlation with higher baseline weight, age and diabetes duration, TZD reduction, insulin use and higher insulin dose reduction, and inversely with baseline HbA1c, HbA1c reduction and South Asian or Afro-Caribbean ethnicity (all $p < 0.001$). Table 1 shows the results of stepwise regressions analyses. The HbA1c change model had 3982 patients with values of baseline HbA1c and weight, weight change, diabetes duration, TZD reduction and insulin use. The weight change model had 3089 patients with values of HbA1c change, baseline weight and HbA1c, ethnicity, age, diabetes duration, TZD reduction and insulin use. The models accounted for 22.0% and 9.5% of the variance of HbA1c change and weight change respectively.

Conclusion: Besides intuitive factors that affect HbA1c and weight outcomes, insulin-treated patients were found to have less HbA1c reduction but more weight reduction after treatment with GLP-1 agonists. Higher total daily insulin dose and longer diabetes duration were also associated with poorer HbA1c reduction. Table 1: Stepwise regression analyses of factors influencing HbA1c and Weight changes among patients treated with exenatide and liraglutide.

Factor	HbA1c reduction, stepwise regression among 3982 patients		Weight reduction, stepwise regression in 3089 patients	
	Adjusted T-value	Adjusted p-value	Adjusted T-value	Adjusted p-value
Baseline HbA1c	30.44	<0.001	-5.94	<0.001
Baseline Weight	-3.79	<0.001	13.29	<0.001
HbA1c change	-	-	-	NS

Life-years, QALYs, costs and numbers needed to treat associated with exenatide once weekly versus insulin and pioglitazone treatment for type 2 diabetes: an Archimedes model simulation

P. Alperin¹, J.A. Gaebler², G. Soto-Campos¹, B. Hoogwerf³, M. Wintle², D. Maggs², A. Blickensderfer², D. Bruhn³, B. Peskin¹;

¹Archimedes Inc., San Francisco, ²Amylin Pharmaceuticals, Inc., San Diego,

³Eli Lilly and Company, Indianapolis, USA.

Background and aims: Exenatide once weekly (ExQW) is a glucagon-like peptide-1 (GLP-1) receptor agonist that improves glycaemia in patients with type 2 diabetes (T2DM) while potentially eliciting weight loss and improvement in cardiovascular risk factors (blood pressure and plasma lipids). In

published trials, ExQW resulted in superior reduction in HbA1c compared to maximum daily doses of sitagliptin and pioglitazone (PIO) on metformin (MET) background, and to titrated insulin glargine. We used the Archimedes Model, a validated, clinically detailed model of physiology, disease, and healthcare delivery, to explore potential long-term benefits of ExQW and to evaluate savings from ExQW that might be achieved through reduced healthcare expenditures.

Materials and methods: We simulated 20 y of treatment (reported annually) in a virtual population ($n = 24,878$) based on individuals with T2DM drawn from the National Health and Nutrition Examination Survey who were on MET±sulphonylureas and who had not yet advanced to insulin (mean age 57 y, BMI 33 kg/m², weight 94 kg, duration of T2DM 9 y, baseline HbA1c 8%). The potential effects of 3 different treatment regimens were modeled at simulation start: 1) advancement to insulin at HbA1c ≥8% (treat to target HbA1c <7%), 2) addition of PIO, and 3) addition of ExQW. ExQW's effect on HbA1c, weight, blood pressure, and lipids was derived from four Phase 3 ExQW clinical trials. Direct medical costs (inpatient, outpatient, ambulatory, treatments) inflated to 2010 USD were derived from the Medicare Current Beneficiary Survey, as well as Medicare Part D data, www.drugstore.com, and published literature. Since ExQW is investigational, antidiabetic therapy costs for ExQW, insulin, and PIO were excluded from the analysis.

Results: At 20 y, undiscounted life years for ExQW, insulin, and PIO were 16.06, 15.87, and 15.81, respectively; quality-adjusted life years (QALYs) were 13.72, 13.52, and 13.46, respectively. Similar gains for ExQW over insulin and PIO were seen at 5 y and 10 y as well. ExQW demonstrated per person-year savings of \$465 and \$327 vs insulin and PIO, respectively, at 5 y, \$528 and \$415 at 10 y, and \$556 and \$539 at 20 y. The numbers of patients needed to treat to prevent one major adverse cardiovascular event (composed of myocardial infarction, stroke, and cardiovascular death) were 94, 53, and 43 for ExQW therapy vs insulin at years 5, 10, and 20, respectively, and 147, 104, and 90 for ExQW vs PIO.

Conclusion: These simulations showed increased life-years and QALYs for ExQW vs insulin and PIO, as well substantial healthcare cost savings. Use of ExQW reduced direct medical costs by \$300 to \$560 vs insulin and PIO per person year throughout the 20 y simulation period. These explorations through simulation modeling provide early indication of the potential of ExQW and underscore the need for confirmation through real-world clinical trials.

DPP-IV inhibitor vildagliptin increases the pancreatic beta cell mass in non-diabetic mice by directly regulating cell kinetics

S. Hamamoto, Y. Kanada, M. Shimoda, K. Tawaramoto, M. Hashiramoto, K. Kaku;

Division of Diabetes, Endocrinology and Metabolism, Kawasaki Medical School, Kurashiki, Japan.

Background and aims: We previously reported that vildagliptin (VILDA) preserved the pancreatic beta cell function and cell mass in diabetic KK-A^y mice probably through its action on the cell kinetics regulation and the anti-oxidative/ER stress mechanism. In this study, to further clarify the proliferative effect of VILDA on beta cells by eliminating the influence of dysmetabolism, we assessed the mode of action of VILDA on beta cell function and cell mass in non-diabetic C57BL/6J mice.

Material and methods: Eight week-old male KK-A^y/TaJcl (KK-A^y) mice and C57BL/6Jcl (B6) mice were divided into VILDA-treated and -untreated (control) groups (n=5). Body weight (BW), food intake, fasted blood glucose (FBG), insulin (FIRI), TG, NEFA and active GLP-1 were measured every 2 weeks. Intraperitoneal insulin tolerance test (ipITT: KK-A^y 2IU/kg BW, B6 0.75IU/kg BW), oral glucose tolerance test (OGTT: 1g/kg BW) and glucose stimulated insulin secretion (GSIS) from isolated pancreatic islet was performed at 12 weeks. Gene expressions specific for the core area of pancreatic islet were analyzed by Laser Capture Microdissection method and real time RT-PCR at 12 weeks. The beta cell mass, cell proliferation and apoptosis were assessed by histological analysis including PCNA, 4HNE, CHOP and TUNEL immunostaining of the islet tissue.

Results: BW, food intake, FBG, FIRI, NEFA and active-GLP-1 were not different between the control and VILDA-treated groups in both KK-A^y and B6 mice. The increased plasma TG level and islet TG content were ameliorated by VILDA treatment in KK-A^y. IpITT demonstrated a significant augmentation of insulin sensitivity by VILDA in both strain of mice. VILDA ameliorated glucose tolerance and induced significantly higher plasma insulin at nearly all of observed points on OGTT in KK-A^y, but these observation were observed at only 15min in B6 mice. GSIS with 16.7mM glucose was more significantly facilitated in VILDA groups than in the controls (KK-A^y: 1.5±0.1 vs. 1.1±0.1 ng/ml/islet, p=0.045, B6: 2.2±0.1 vs. 1.7±0.1 ng/ml/islet, p=0.042). The pancreatic beta cell mass and islet insulin content were greater in VILDA-treated mice than in the control mice (beta cell mass: KK-A^y 5.0±0.4 vs. 2.9±0.4 mg, p=0.016, B6 1.2±0.1 vs. 0.8±0.2 mg, p=0.047). The mRNA levels of Hlx-9, PDX-1, and ERK1 associated with cell differentiation/proliferation were significantly higher in both VILDA treated mice than in the control mice. VILDA significantly down-regulated XBP-1 related with ER stress, Caspase3 and CAD gene expression related with cell apoptosis, and up-regulated GSH-Px and SOD2 gene expression related with anti-oxidative stress in KK-A^y, but not in B6 mice. Morphometric results for PCNA, 4HNE, CHOP and TUNEL observed corresponded with the data obtained in gene expression analysis.

Conclusion: The present results suggest that vildagliptin increases the pancreatic beta-cell mass in non-diabetic mice through directly accelerating cell differentiation/proliferation.

808

Effect of DPP-4 inhibitor vildagliptin on pancreatic beta cell failure in beta cell-specific C/EBPβ transgenic mice

S. Shimizu¹, T. Hosooka², T. Matsuda², S.I. Asahara², S. Seino², Y. Kido^{1,2};

¹Department of Biophysics, Division of Medical Chemistry, Kobe University Graduate School of Health Sciences, ²Department of Internal Medicine, Division of Diabetes and Endocrinology, Kobe University Graduate School of Medicine, Japan.

Background and aims: Dipeptidyl peptidase-4 (DPP-4) inhibitor lowers blood glucose levels by increasing insulin secretion from β cells. Although the effect of DPP-4 inhibitor on glycemic control is quite clear, it remains to be determined whether this reagent improves the pathogenic features of type 2 diabetes, such as endoplasmic reticulum (ER) stress and the reduction of β cell mass. We have recently reported that accumulation of the transcription factor C/EBPβ in β cells causes ER stress and a reduction in β cell mass lead-

ing to β cell failure. The present study aimed to examine whether the DPP-4 inhibitor vildagliptin reduces ER stress and preserves pancreatic β cell mass in β cell-specific C/EBPβ transgenic mice.

Materials and methods: By inserting the cDNA of C/EBPβ downstream of rat insulin promoter 2, we obtained two lines of transgenic mice, namely TG1 and TG2, which are different from each other in terms of the expression levels.

Results: β cell-specific C/EBPβ transgenic mice (TG1), in which the expression of C/EBPβ was 3-fold higher than that in wild-type mice (WT), showed a non-fasting glucose level of approximately 200 mg/dl, with increased ER stress and reduced β cell mass. TG1 and WT were orally treated with or without vildagliptin (vilda) dissolved in water (0.6 mg/ml) from 4 weeks of age. Treatment with vilda in TG1 markedly ameliorated hyperglycemia and increased serum insulin levels (WT with vilda: 136 ± 4.0, WT without vilda: 132 ± 4.8, TG1 with vilda: 154 ± 11.1, and TG1 without vilda: 193 ± 7.2; p < 0.01). TG1 treated with vilda also showed a significant improvement in glucose tolerance concomitant with the increased insulin secretion compared to TG1 without treatment. Immunostaining analyses of insulin and glucagon of the pancreatic islets after 8 weeks treatment showed that TG1 treated with vilda exhibited a 2-fold increase in β cell mass compared to TG1 without treatment, although they still did not reach the WT level. We next established C/EBPβ-overexpressing β cell lines and, using the GLP-1 receptor agonist exenatide, examined the effect of activation of the GLP-1 pathway on C/EBPβ-mediated ER stress and the reduced β-cell mass. C/EBPβ overexpression induced ER stress, as detected by the phosphorylation of PERK, eif2α, and c-jun, and activated components of the apoptotic pathway, including CHOP and cleaved caspase-3. Treatment with exenatide (10 nM) markedly reduced ER stress and activation of the apoptotic pathway induced by C/EBPβ overexpression.

Conclusion: The DPP-4 inhibitor vildagliptin reduced the β cell failure in β cell-specific C/EBPβ transgenic mice by increasing β cell mass. This effect might be mediated through the reduction of ER stress and apoptosis in β cells.

809

A metabolomic study of GLP-1 analogue and glucagon receptor (GCGR) antagonist in DIO mice

W. Gu¹, D.J. Lloyd¹, N. Chinookswong¹, R. Komorowski¹, G. Sivits Jr¹, M. Graham¹, K.A. Winters¹, H. Yan², L.G. Boros³, M.M. Véniant¹;

¹Metabolic Disorders, Amgen Inc, Thousand Oaks, ²Protein Science, Amgen Inc, Thousand Oaks, ³SiDMap, LLC, Los Angeles, USA.

Background: Agonizing the GLP-1 receptor and antagonizing the glucagon receptor are two therapeutic approaches for achieving improved glycemic control. In preclinical animal models both GLP-1R agonists and GCGR antagonists exhibit robust efficacy in lowering blood glucose levels. Although the two hormones control distinct pathways in regulating glucose production and disposal, recent studies have demonstrated that the two approaches are interdependent in achieving maximal therapeutic efficacy. These findings, however, do not imply that GLP-1 agonists and GCGR antagonists have identical effects on all aspects of glucose homeostasis. The two agents may have distinct effects on energy and glucose metabolism.

Aims: To investigate the pharmacologic contributions of directly agonizing the GLP-1 receptor or antagonizing GCGR on energy state and glucose homeostasis in diet-induced obese (DIO) mice. To gain molecular insight on the mechanisms of action by conducting metabolomic study using stable isotope-based dynamic metabolic profiling (SiDMap) to analyze key metabolic pathways.

Material and methods: GCGR Ab is a human monoclonal IgG that antagonizes GCGR. In cells expressing recombinant mouse GCGR, GCGR Ab inhibited glucagon-induced cAMP elevation (IC₅₀ ~1.8 nM). The GLP-1 analog is a GLP-1 PEGylated with a C-terminal cysteine-alanine extension to give GLP-1 compound 23 (EC₅₀ ~0.13 nM). DIO mice were injected i.p. with either PBS (vehicle), GLP-1-(23) 10 µg/mouse, or GCGR Ab 1 mg/kg. After the baseline blood glucose levels were measured mice were injected i.p. with uniformly labeled ¹³C glucose tracer ([U-¹³C]₆]-D-glucose 2 g/kg. At 90 min after tracer injection, blood was collected, and liver, skeletal muscle (gastrocnemius/soleus), kidney, and white adipose tissues (epididymal) were removed. Metabolism of [U-¹³C]₆-D-glucose produces several stable, non-radiating isotope-labeled intermediary metabolite species. These isotopomers were readily separated and measured by using gas chromatography/mass spectrometry techniques.

Results: Although the two agents induced rapid clearance of administered tracer glucose, the metabolic fate of the labeled glucose showed both overlap-

ping and distinct paths in mice treated with the two different anti-diabetic agents. The rapid disposal of the glucose tracer by both agents was mediated by pathways including increased glycolysis and TCA cycle anaplerosis, resulting in a surge in plasma lactate and glutamate levels. Both agents also increased glucose oxidation in the liver and kidney, producing ATP and carbon dioxide. GLP-1-(23) treatment uniquely exhibited increased pentose cycle flux in the liver and kidneys. This biochemical reaction yielded additional NADPH, which is required by de novo fatty acid synthesis. This is consistent with the report that GLP-1 stimulates glucose-derived de novo fatty acid synthesis during insulin release.

Conclusion: Our data indicate that the two agents exhibit differential effects on energy metabolism and certain aspects of glucose homeostasis in a DIO rodent model. These data contribute to an understanding of the benefits and limitations of these two therapeutic agents.

810

Protective effects of the GLP-1 receptor agonist lixisenatide on ischaemia-reperfusion-induced myocardial infarction in an isolated rat heart model

H. Ruetten¹, J. Huber, S. Meister, A.W. Herling, U. Werner;
sanofi aventis Deutschland GmbH, Frankfurt am Main, Germany.

Background and aims: Endogenous glucagon-like peptide-1 (GLP-1) is an incretin peptide secreted from intestinal L-cells in response to food intake. It stimulates insulin release from the pancreas when blood glucose levels are elevated. In addition, there is some evidence that GLP-1 may have beneficial cardiovascular effects. We assessed the cardioprotective effect of lixisenatide, a novel synthetic GLP-1 receptor agonist, native GLP-1 (GLP-17-36 amide) and liraglutide in isolated Langendorff-perfused rat hearts during regional ischemia and reperfusion.

Materials and methods: We performed transient occlusion of the left anterior descending coronary artery for 45 minutes followed by a reperfusion period of 120 minutes to permit simultaneous recording of left ventricular pressure, contractility, heart rate and coronary flow. Infarct size was determined by planimetry.

Results: Administration of lixisenatide at 0.3 nM starting 10 minutes prior to and during reperfusion significantly reduced myocardial infarct-size by 36% ($p=0.0028$ vs vehicle control). Native GLP-1 and liraglutide (both also at 0.3 nM) reduced myocardial infarct-size by 32% ($p=0.0071$ vs vehicle control) and 29% ($p=0.0159$ vs vehicle control), respectively. The observed cardioprotective effect was not associated with a significant change in cardiac hemodynamics, particularly coronary flow. However, all GLP-1 receptor agonists stimulated myocardial glucose uptake during recovery from regional ischemia, suggesting a direct cardiac effect.

Conclusion: The novel GLP-1 receptor agonist lixisenatide offers protection against myocardial ischemia-reperfusion infarction in isolated rat hearts. This finding may represent a novel therapeutic benefit and supports the rationale to study lixisenatide in a cardiovascular outcome trial.

Effect of linagliptin on infarction size and cardiac function in rats after myocardial ischaemia reperfusion

T. Pfab¹, Y. Sharkovska², M. Alter², K. von Websky², M. Mark³, T. Klein³, B. Hoher⁴;

¹Department of Nephrology, Charité, Berlin, ²Center for Cardiovascular Research, Charité, Berlin, ³Boehringer Ingelheim, Biberach, ⁴Institute of Nutritional Science, University of Potsdam, Germany.

Background and aims: Dipeptidyl peptidase-4 (DPP-4) inhibition has been reported to have beneficial effects on myocardial ischaemia. Mechanisms behind these effects could include the involvement of stromal cell-derived factor (SDF)-1 and/or incretin receptor-dependent pathways that improve tissue repair. In addition, as some antihyperglycaemic agents have been associated with adverse cardiovascular (CV) outcomes, it is critical to ensure that agents in development, such as the DPP-4 inhibitor linagliptin, do not carry an increased CV risk. The objective of this study was to evaluate the cardiac effects of linagliptin in a rat ischaemia-reperfusion injury (I/R) model.

Materials and methods: Rats were divided into three groups: sham, I/R and I/R plus linagliptin ($n=16-18$ per group). Linagliptin was given once daily (3 mg/kg) starting 30 days before I/R. I/R was induced by ligation of the left

anterior descending coronary artery for 30 min. Echocardiography was performed after 58 days and cardiac catheterization after 60 days.

Results: Linagliptin significantly reduced the proportion of infarcted tissue relative to the total area at risk (-21% ; $p < 0.001$) as well as the absolute infarction size (-18% ; $p < 0.05$). In addition, glucagon-like peptide-1 (GLP-1) levels were increased 18-fold ($p < 0.0001$) and DPP-4 activity was reduced by 78% ($p < 0.0001$). Left ventricular left end diastolic and systolic pressure as well as all echocardiography parameters were similar between groups, with a significant improvement of isovolumetric contractility indices (dp/dt_{min}) from -4771 ± 79 mmHg/s to -4957 ± 73 mmHg/s.

Conclusion: These data further support a cardioprotective function of linagliptin in the setting of acute myocardial infarction.

GLP-1 receptor expression in the human thyroid gland

B. Gier¹, P.C. Butler¹, C.K. Lai², M.M. DeNicola², M.W. Yeh³;

¹Larry Hillblom Islet Research Center, ²Department of Pathology and Laboratory Medicine, ³Endocrine Surgical Unit, Department of Surgery, David Geffen School of Medicine, Los Angeles, USA.

Background and aims: Glucagon like peptide-1 (GLP-1) mimetic therapy induces C-cell hyperplasia and medullary thyroid tumors in rodents. We sought to establish if C-cells in human medullary thyroid carcinoma (MTC), C-cell hyperplasia (CCH), papillary thyroid carcinoma (PTC) or normal human thyroid express the GLP-1 receptor (GLP-1R).

Materials and methods: Expression of GLP-1R as well as the C-cell marker calcitonin was determined by immunofluorescent labeling of thyroid tissue samples including medullary thyroid carcinoma, C-cell hyperplasia, papillary thyroid carcinoma as well as normal thyroid sections. GLP-1R antibody validation was carried out by transfecting cell lines that do not express the GLP-1R with human GLP-1R, specificity being documented by Western Blotting and immunofluorescence.

Results: Normal thyroid. GLP-1R expression was detected in 35% of C-cells in 15 normal control thyroid lobes. A total of 1,979 C-cells (range 12-433 per section) were identified by calcitonin labeling in these sections. Medullary thyroid carcinoma. Colocalisation of GLP-1R and calcitonin was observed in a varying proportion of C-cells in 11 of the 12 MTC examined. In 6 cases, more than 70% of C-cells were immunoreactive for GLP-1R. C-cell hyperplasia. Thyroids from 4 individuals with reactive (to inflammatory) CCH showed clear labeling for GLP-1R in all cells positive for calcitonin. Also, GLP-1 R expression was detected in all 5 individuals with nodular/neoplastic CCH due to MEN-2A or FMTC germline mutations. In addition, GLP-1R immunoreactivity was found in the medullary thyroid microcarcinomas present in these cases. Papillary thyroid carcinoma. Unexpectedly, we also detected GLP-1R expression in thyroid follicular cells in 3 of 17 of the PTC examined.

Conclusion: In humans, the GLP-1R is expressed in ~30% of C-cells in normal thyroid and a higher proportion of C-cells in C-cell hyperplasia and medullary thyroid carcinomas. Of concern, GLP-1R expression is also present in ~20% of papillary thyroid carcinomas, the latter being present in ~8% of the adult population. While it is unknown if GLP-1 induces proliferation of follicular or C-cells expressing the GLP-1 receptor, it will be important to follow individuals treated with GLP1 based therapy to exclude an increase in the incidence of medullary or papillary thyroid carcinomas.

813

The GLP-1 receptor regulates plasma clearance of exenatide following a three-month exposure in mice

D.G. Parkes, E. Sablan, C. Polizzi, K. Tatarkiewicz;
Amylin Pharmaceuticals, Inc., San Diego, USA.

Background and aims: Exenatide is a glucagon-like peptide-1 receptor (GLP-1 R) agonist, which improves glycaemic control in patients with type 2 diabetes. The GLP-1R is expressed in multiple tissues and its activation is associated with numerous metabolic improvements including enhanced insulin secretion, slowing of gastric emptying, decreased food intake, and inhibition of hepatic steatosis. Based on current literature, it has not been established that the long-term glycaemic benefits of exenatide are exclusively mediated via activation of the GLP-1R. The aim of the present study was to examine the metabolic and pharmacokinetic effects of a supramaximal con-

tinuously infused dose of exenatide for 3 months in mice lacking a functional GLP-1R (GLP-1R KO).

Materials and methods: GLP-1R KO and wild-type (WT) control mice were fed a high fat diet (58% fat). Exenatide (30 nmol/kg/d) was continuously infused via osmotic mini-pumps for 3 months. HbA1c, blood glucose, plasma insulin, amylase, lipase, alanine aminotransferase (ALT), aspartate aminotransferase (AST), body weight (BW), and food intake (FI) were measured. Oral glucose tolerance (OGTT) and gastric emptying were assessed at the end of the study. Terminal organ weights, hepatic lipid content, and plasma exenatide concentrations were measured. Results are presented as mean±SEM. The differences between groups were considered statistically significant for $P < 0.05$ (t-test).

Results: After 3 months treatment, no significant effects were observed with exenatide infusion on any metabolic endpoint in GLP-1R KO mice. In contrast, in WT mice exenatide significantly decreased vehicle (Veh)-corrected glucose by 25 ± 5 mg/dL, BW by $40 \pm 2\%$, and cumulative FI (maximally by $30 \pm 3\%$ at Week 2). Exenatide significantly reduced plasma insulin (0.5 ± 0.2 ng/mL) vs Veh (1.8 ± 0.5 ng/mL) and ALT (20 ± 4 U/L) vs Veh (47 ± 10 U/L). Exenatide reduced glucose excursion during an OGTT (AUC_{0-2h} (mg·h/dL) (642 ± 70) vs Veh (972 ± 93)). Hepatic lipid content was reduced by exenatide (g/g) (0.059 ± 0.004) in comparison to Veh (0.107 ± 0.010). Exenatide increased pancreatic (0.0097 ± 0.0004) and renal (0.0101 ± 0.0002) weight (g/g BW) vs respective Veh controls (0.0058 ± 0.0005 and 0.0081 ± 0.0005). Exenatide had no significant effect on HbA1c, amylase, lipase, gastric emptying, or liver weight under these experimental conditions. Intriguingly, plasma exenatide concentrations (450 ± 139 pg/mL) were approximately 8-fold higher in GLP-1R KO mice, than in WT controls (55 ± 20 pg/mL) ($P < 0.02$).

Conclusion: These results show for the first time that a functional GLP-1R is required for exenatide to exert its long-term effects in mice. The observed difference in plasma exenatide concentrations between wild type and GLP-1R KO mice suggests that GLP-1 receptors may play a significant functional role in the plasma and/or renal clearance of exenatide, and perhaps other related peptides. Furthermore, novel GLP-1 receptors may not be substantially involved in the chronic metabolic actions of exenatide in mice.

Effects of different sweet preloads on incretin hormone responses, gastric emptying and postprandial glycaemia in healthy humans

T. Wu¹, B. Zhao¹, M. Bound¹, H.L. Checklin¹, M. Bellon², T.J. Little¹, R.L. Young³, K.L. Jones¹, M. Horowitz², C.K. Rayner¹

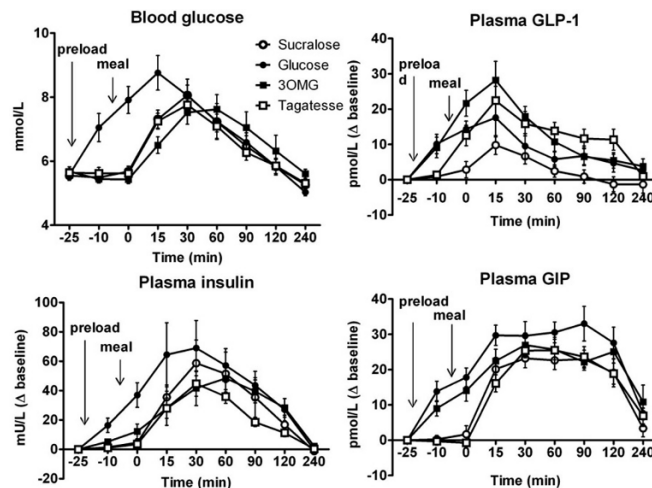

¹Discipline of Medicine, University of Adelaide, ²Department of Nuclear Medicine, Royal Adelaide Hospital, ³Nerve Gut Laboratory, Royal Adelaide Hospital, Australia.

Background and aims: Macronutrient 'preloads' taken in advance of a meal have the capacity to stimulate glucagon-like peptide 1 (GLP-1) from the distal, and glucose-dependent insulinotropic polypeptide (GIP) from the proximal gut, slow gastric emptying, and reduce postprandial glycaemic excursions in health and type 2 diabetes. These effects may potentially be signaled by sodium-glucose co-transporter 1 (SGLT1) and/or sweet taste receptors after sweet 'preloads'. We sought to compare the effects of four sweet 'preloads' on GIP and GLP-1 release, gastric emptying and glycaemia after a subsequent meal.

Materials and methods: 10 healthy subjects were studied on 4 days each in random order. On each day, subjects drank a 400mL 'preload' containing either 40g glucose, 40g Tagatose™ (a poorly absorbed mixture of tagatose and isomalt), 40g 3-O-methylglucose (3OMG; a non-metabolised substrate of SGLT1), or 60 mg sucralose (an artificial sweetener of equivalent sweetness) in water. 15 minutes later, they ate a mashed potato meal labelled with ¹³C octanoic acid. Blood glucose, total GLP-1 and GIP, insulin, and gastric emptying (breath test) were evaluated. Data are mean ± SEM.

Results: Both glucose and 3OMG stimulated GLP-1 and GIP release in advance of the meal ($P < 0.05$ for each), whereas Tagatose™ and sucralose did not. The GLP-1 response to the meal over 240 min (incremental area under the curve) was greater after glucose, 3OMG, and Tagatose™ than sucralose ($P < 0.01$ for each), and GLP-1 stimulation was later after Tagatose™. Blood glucose in the first 30 min after the meal (incremental area under the curve) was greatest after glucose ($P < 0.01$), but lower after 3OMG than sucralose ($P < 0.05$), while insulin was also greatest after glucose ($P < 0.05$). Gastric emptying was slower after 3OMG (half-emptying time 207 ± 17 min) and Tagatose™ (275 ± 39 min) than sucralose (165 ± 12 min, $P < 0.05$), and tended to be slower after glucose (245 ± 59 min) than sucralose ($P = 0.15$), without any difference between glucose, 3OMG and Tagatose™.

Conclusion: In healthy humans, SGLT-1 substrates, regardless of whether they are metabolised, stimulate GLP-1 and GIP and slow gastric emptying, whereas sweet taste per se has no effects. Poorly absorbed sweet tastants, which probably expose a greater length of gut to nutrient, result in later GLP-1 secretion and slowing of gastric emptying, but not GIP release. These observations can help optimise preloads for glycaemic control.

Metabolic effects of sitagliptin in patients with type 2 diabetes

E. Muscelli¹, A. Casolaro¹, A. Gastaldelli², A. Mari³, G. Seghieri¹, Y. Chen⁴, M. Alba⁴, J.J. Holst⁵, E. Ferrannini¹

¹University of Pisa, Italy, ²C N R Institute of Clinical Physiology, Pisa, Italy, ³Institute of Biomedical Engineering, Padova, Italy, ⁴Merck Sharp & Dohme Corp., Whitehouse Station, USA, ⁵University of Copenhagen, Denmark.

Background and aims: Although the antihyperglycaemic effect of DPP4 inhibitors is thought to be mainly due to potentiation of insulin secretion via GLP-1, we aimed at assessing the integrated metabolic response to chronic DPP4 inhibitor treatment.

Materials and methods: We administered a mixed meal (MM) with 2 glucose (G) tracers (6,6D₂-G infused, D₁-G ingested) to 47 T2D patients (pts) (age=56±7 yrs [mean±SD], BMI=29.9±4.2 kg/m², HbA_{1c}=7.4±0.8%) and 7 age- and BMI-matched controls (C); pts were re-studied after 6 weeks of double-blind, randomised treatment with sitagliptin (sita, 100 mg/day, n=25) or placebo (plb, n=22).

Results: Changes from baseline (∅) in fasting G (-0.94 ± 0.89 vs 0.06 ± 1.78 mmol/L, $p < 0.01$) and G area-under-curve (AUC) (-594 ± 39 vs $+100 \pm 594$ mmol·L⁻¹·5h, $p < 0.0001$) were greater with sita than plb, respectively, in parallel with a lower appearance of oral G ($\Delta AUC = -356 \pm 917$ vs $+144 \pm 600$ μmol kg⁻¹·5h, $p = 0.01$), and a trend to greater suppression of endogenous G output ($\Delta AUC = -183 \pm 450$ vs -39 ± 411 μmol kg⁻¹·5h, $p = 0.1$). The plasma branched-chain aminoacid response was significantly lower after sita than plb (-8.76 ± 4.38 vs 3.96 ± 5.89 mmol·L⁻¹·5h, $p = 0.01$). Insulin sensitivity, significantly lower at baseline in pts vs C (271 ± 42 ml min⁻¹·m⁻² vs 389 ± 27 , $p < 0.0001$), improved by 11% after treatment ($\Delta = 30 \pm 30$ vs 3 ± 41 ml min⁻¹·m⁻², sita vs plb, $p < 0.01$). Baseline β-cell G sensitivity (β-GS), lower in pts vs C ($32[30]$ pmol min⁻¹·m⁻²·mM⁻¹ vs $98[115]$, $p = 0.0002$), improved with sita vs plb ($19[29]$ vs $5[21]$, $p = 0.01$). Glucagon and total GIP AUCs decreased ($p = 0.03$ and 0.01 , respectively) with sita vs plb, while total GLP-1 response was maintained. At baseline and follow-up, the G response to MM was matched by isoglycaemic (iso-G) IV G infusion. Sita vs plb increased β-GS with both MM and iso-G ($p = 0.01$ and $p = 0.002$, respectively), but the relative difference was unchanged from baseline.

Conclusion: Chronic sita treatment improves glycaemic control by lowering appearance of oral G and aminoacids, postprandial G release and glucagon response. Insulin sensitivity and β-cell G sensitivity also improve. While reversal of glucose toxicity may at least partly contribute to these findings, the results are consistent with potentiation of active GLP-1 effects on glucagon and β-cell function.

816

Weight loss of 3% or more in a 12-month period is associated with glycaemic control in newly treated type 2 diabetes patients in the usual care setting

J. Mukherjee¹, C. McAdam-Marx², X. Ye², S.K. Unni², D. Brixner²;

¹Global Health Economics and Outcomes Research, Bristol-Myers Squibb, Wallingford, ²Outcomes Research Center, University of Utah, Salt Lake City, USA.

Background and aims: Weight gain is reluctantly accepted as a trade-off for attaining glycemic control in patients with type 2 diabetes (T2DM), but this paradigm is poised to shift with the availability of new agents not associated with weight gain. This study evaluated the correlation between weight change and glycemic control in newly treated patients with T2DM in a usual care setting.

Materials and methods: Patients age 18+ years with T2DM newly treated with select antidiabetic agents including those associated with weight gain (sulfonylurea [SU], thiazolidinedione [TZD]) and those which are not (metformin [MET], DPP-4 inhibitor [DPP-4], or GLP-1 agonist [GLP-1]) as monotherapy were identified in a national electronic medical record (EMR) database from 1/1/2000 to 6/30/2010. Patients were required to have 410 days of EMR activity before and after the first antidiabetic prescription (index date). Outcomes included glycemic control (HbA1c <7% or ≥7%) and weight change (weight gain ≥3%, weight neutral [change <3%] and weight loss ≥3%) from baseline to 12 months. Logistic regression was used to identify the odds of attaining HbA1c goal with weight loss or weight gain vs. weight neutrality, controlling for baseline treatment and patient characteristics.

Results: The study included 28,290 patients; SU (6,283, 22.2%), TZD (2,978, 10.5%), MET (18,328, 64.8%), DPP-4 (456, 1.6%) and GLP-1 (245, 0.9%). Overall mean (±SD) age was 61 ±11.8 years; 46.4% were male. Mean (±SD) baseline weight and HbA1c were 95.3±22.7 kg and 7.5±1.6%, respectively; 25.5% had an HbA1c <7.0%. After 12 months, mean (±SD) weight change from baseline was -1.6±6.5 kg (p<0.001). Weight gain, weight loss, and weight neutrality were observed in 18.3%, 35.1% and 46.6% patients, respectively. The mean (±SD) reduction in HbA1c from baseline at 12 months was -0.7±1.6% (p<0.001). HbA1c goal attainment was achieved in 44.9% of all patients, and in 58.0% patients with weight loss, 36.6% patients with weight gain, and 38.3% patients who were weight neutral. Patients losing ≥3% of body weight were more likely to attain HbA1c goal relative to weight neutral patients (OR=2.7; 95% CI 2.55–2.87); those who gained weight were less likely to attain HbA1c goal (OR=0.77 95% CI 0.71–0.83). Baseline weight and the weight-effect properties of the baseline antidiabetic therapy currently did not predict HbA1c goal attainment.

Conclusion: Weight loss of ≥3% of body weight is a significant predictor of HbA1c goal attainment while baseline weight and weight-effect properties of the prescribed antidiabetic agents currently available are not. Future research will evaluate the associations between adherence and weight change, and their impact on glycemic outcomes.

PS 067 Incretins: safety considerations for pancreas and kidney

817

No worsening but improvement of exocrine pancreatic inflammation in spontaneously diabetic GK rats by DPP-IV inhibitor, vildagliptin

K. Takahashi, H. Mizukami, W. Inaba, S. Yagihashi;

Pathology and Molecular Medicine, Hirotsuki University Graduate School of Medicine, Japan.

Background and aims: Dipeptidyl-peptidase-IV (DPP-IV) inhibitor has emerged as a new type of diabetes treatment. There is a concern, however, for the effects on the exocrine pancreas. In one study, there was an increased occurrence of acute pancreatitis and ductal cell proliferation in human-IAPP transgenic rats treated with sitagliptin. The others found comparable episodes of pancreatitis in sitagliptin-treated subjects to those in healthy individuals. We therefore explored the long-term effects of DPP-IV inhibitor on the exocrine pancreas in GK rats, a model of non-obese type 2 diabetes.

Materials and methods: GK rats 4 weeks of age were given a DPP-IV inhibitor (vildagliptin 15mg/kg)(VG) twice a day by gavage for following 18 weeks. Control GK rats were given saline alone. Non-diabetic Wistar rats were divided into 2 groups in the same way. At end, all the animals were sacrificed and pancreases were subjected to the pathological evaluation with morphometric analysis.

Results: VG treatment did not influence on the body weight in either control or GK rats. While daily food intake was slightly reduced in GK rats, it was not the case in normal Wistar rats. There was a significant increase in serum amylase in GK rats compared to Wistar rats (719±14 vs 555±31, p<0.01) (mean±SE IU/L) and the value was normalized in VG-treated GK rats (501±42, p<0.01). VG treatment did not alter the values in control Wistar rats. On histology, GK rats showed scattered inflammatory foci in the parenchyma of exocrine pancreas, periductal areas and around small vessels. VG treatment lessened the severity of inflammation in GK rats and quantitation confirmed the decrease in the inflammatory foci. There was no significant difference in the rate of proliferating cells in duct or acinar cells by Ki67 staining between GK and Wistar rats. VG treatment did not influence on the proliferation activity in these cells. Acinar cells undergoing apoptosis detected by TUNEL staining (#/10hpf) were significantly increased in GK rats compared to Wistar rats (8.3±0.9 vs 2.7±0.7, p<0.01). VG treatment significantly suppressed the frequency of apoptotic cells (4.7±0.7, p<0.01).

Conclusion: Our present study demonstrated that VG treatment significantly suppressed inflammatory changes in the exocrine pancreas in GK rats without an increase in duct cell proliferation. It remains open to question whether the effects are specific to VG or GK rats, or in case common with other DPP-IV inhibitors.

818

Long-term exposure of exenatide does not adversely affect exocrine pancreas structure and function in Diabetic Zucker Fatty (ZDF) rats

K. Tatarkiewicz, P. Belanger, G. Gu, D. Roy, D.G. Parkes;

Amylin Pharmaceuticals, Inc., San Diego, USA.

Background and aims: Type 2 diabetes is a risk factor for the development of pancreatitis or pancreatic cancer. Previously, we have shown that exenatide did not exacerbate, but improved experimental pancreatitis in several rodent models. The aim of the present study was to characterize the effects of exenatide on exocrine pancreatic structure and function in ZDF rats treated chronically with exenatide at doses yielding plasma concentrations several fold higher than clinical exposure.

Materials and methods: Rats were dosed subcutaneously with exenatide (6, 40, 250 µg/kg/d split over 2 injections) or vehicle for 3 consecutive months. HbA1c, fasting serum lipase, amylase, glucose and insulin, body weight, and food consumption were measured monthly. Plasma exenatide concentrations were assessed at the beginning and end of the study. Pancreata were weighed and processed for histology. Morphometric analysis of duct cell proliferation and apoptosis was performed via immunostaining with cytokeratin (duct), Ki-67 (proliferation), and TUNEL (apoptosis). The same endpoints were measured after 1-month recovery in a subset of animals from each group.

Results are presented as mean \pm SD. The differences between groups were considered statistically significant when $P<0.05$ (ANOVA).

Results: As expected, exenatide improved glycaemic endpoints including a decrease in HbA_{1c} and glucose, and an increase in insulin and islet size, in comparison to vehicle. Exenatide had no effect on lipase. Treatment with exenatide was associated with a small, but significant increase in amylase concentrations (U/L) (exenatide 6 μ g/kg/d = 3,266 \pm 391, exenatide 40 μ g/kg/d = 3,517 \pm 404, exenatide 250 μ g/kg/d = 3,286 \pm 322) vs vehicle (2,706 \pm 289, $P<0.05$) at 3 months. There was no significant difference between all groups in amylase (U/L) at the end of the recovery period (exenatide 6 μ g/kg/d = 3,310 \pm 343, exenatide 40 μ g/kg/d = 3,376 \pm 330, exenatide 250 μ g/kg/d = 3,261 \pm 473, vehicle = 3,395 \pm 1,016). At the beginning of the study, the area under the exenatide plasma concentration-time curve (AUC_{0-8h}) ranged from 1 to 63 ng·h/mL and the maximal concentration (C_{max}) ranged from 1 to 43 ng/mL. These values were higher than AUC_{0-8h} and C_{max} seen with the highest recommended dose of exenatide in humans (20 μ g/d) by approximately 1- to 61-fold and 5- to 206 -fold, respectively. AUC_{0-8h} increased substantially after 3 months with the accumulation ratio ranging from 2.7 to 4.4. Importantly, exenatide improved survival of animals (100% survival in all treatment groups) in comparison to vehicle controls (60%) during the dosing period. There was no exenatide-related difference in absolute or relative pancreatic weight. Histological analysis revealed no changes in pancreatic exocrine tissue morphology in animals treated with exenatide. Mean ductal cell proliferation rate was low (<0.15%) and similar for all groups at the end of the treatment and after the recovery period. There was no significant difference in ductal cell apoptosis between all groups.

Conclusion: Long-term exposure to exenatide at plasma concentrations several fold higher than therapeutic levels in humans resulted in the expected metabolic benefits. Furthermore, exenatide improved animal survival and did not adversely affect exocrine pancreas structure and function in a rat model of type 2 diabetes.

819

Comparison of vildagliptin with placebo in a 24-week study of 221 patients with type 2 diabetes and severe renal impairment (eGFR<30)

W. Kothny¹, A. Schweizer², R. Naik¹, P.-H. Groop³, Q. Shao¹, V. Lukashevich¹; ¹Novartis Pharmaceuticals Corporation, East Hanover, USA, ²Novartis Pharma AG, Basel, Switzerland, ³Helsinki University Hospital, Finland.

Background and aims: Patients with type 2 diabetes (T2DM) have an increased prevalence of decreased kidney function, which progresses with increasing disease duration. In addition, pharmacokinetic data for vildagliptin, an orally effective dipeptidyl peptidase-4 (DPP-4) inhibitor, indicated an approximately 2-fold increased exposure in patients with severe renal impairment. It was therefore of interest to assess the safety and tolerability of vildagliptin as well as its efficacy in patients with T2DM and severe renal impairment.

Materials and methods: In a 24-week, multicenter, randomized, double-blind, parallel-group, placebo-controlled study, 221 patients with T2DM and severe renal impairment [estimated GFR (eGFR) <30 ml/min per 1.73 m² according to MDRD] were randomized to vildagliptin 50 mg qd (N=124) and placebo (N=97). Oral antidiabetic or insulin therapy present at enrollment (97.3%) was continued throughout the study. The primary endpoint was safety and tolerability; overall safety as well as specific safety areas of interest (hepatic, skin, edema and pancreatitis) are presented. The change in HbA_{1c} from baseline to study endpoint was analyzed by ANCOVA as a protocol-specified exploratory objective. The study also included 294 patients with moderate renal impairment, who are discussed in an accompanying abstract.

Results: Baseline and demographic characteristics of the randomized patients were representative of a T2DM population with severe renal impairment: mean eGFR = 21.5 ml/min per 1.73 m², mean age = 64.3 years (with 50.7% of patients \geq 65 years and 15.4% \geq 75 years), mean BMI = 30.0 kg/m², mean HbA_{1c} = 7.7% (with 69.2% \leq 8.0%) and mean disease duration = 18.1 years. 80.5% of patients were treated with insulin at study entry. Overall AEs, serious AEs, discontinuations due to AEs and deaths were reported with a comparable frequency in patients receiving vildagliptin and patients receiving placebo as shown in Table 1. There were no clinically relevant or statistically significant differences between treatment groups for hepatic-related AEs (0.8% with vildagliptin vs. 1.0% with placebo; $p>0.999$), skin-related AEs (2.4% vs. 6.2%; $p=0.185$), edema-related AEs (16.9% vs. 18.6%; $p=0.859$) and pancreatitis-related AEs (0% in both treatment groups). One patient each in the vildagliptin (0.8%) and placebo (1.1%) treatment groups had treatment-emergent, persistent ALT/AST elevations \geq 3xULN. Mean HbA_{1c} was reduced

in vildagliptin-treated patients by -0.88% from a baseline of 7.69%, with the placebo-subtracted reduction being -0.56% (95% CI -0.83 to -0.30, $p<0.0001$). **Conclusion:** Vildagliptin 50 mg qd is well tolerated and efficacious in T2DM patients with severe renal impairment.

Efficacy of vildagliptin therapy in combination with insulin in patients with type 2 diabetes and severe renal impairment

V. Lukashevich¹, A. Schweizer², J. Foley¹, Q. Shao¹, P.-H. Groop³, W. Kothny¹; ¹Novartis Pharmaceuticals Corporation, East Hanover, USA, ²Novartis Pharma AG, Basel, Switzerland, ³Helsinki University Hospital, Finland.

Background and aims: Vildagliptin, a potent and selective DPP-4 inhibitor, improves islet function by increasing α - and β -cell responsiveness to glucose. In drug naive patients with T2DM there was a reduction in HbA_{1c} of 1.0 % from a baseline of 8.7% and a reduction of 0.5% from baseline of 7.3%. In patients where vildagliptin was added to metformin there was a 1.1% reduction in HbA_{1c} from baseline of 8.4% and a 0.7% reduction from a baseline of 7.8%. As most patients in this study had diabetes < 7 years, the question arises as to whether patients of longer duration of diabetes and with renal impairment, where beta cell sensitivity to glucose is often severely impaired, would be responsive to vildagliptin.

Materials and methods: The efficacy of vildagliptin in a subgroup of T2DM patients with severe renal impairment [estimated GFR (eGFR) < 30 ml/min per (1.73 m²) according to MDRD] inadequately controlled on insulin (HbA_{1c} of \geq 6.5 and \leq 10 %) from a large double blind placebo controlled study was analyzed. Vildagliptin 50 mg qd or matching placebo was added to the background therapy of insulin as monotherapy or in combination with oral anti-diabetic drugs (OADs) that remained unchanged through 24-week treatment. Efficacy was assessed as HbA_{1c} reductions at study endpoint from baseline and versus placebo using ANCOVA model. Safety and tolerability were also evaluated.

Results: 221 patients with severe renal impairment were randomized in the main trial. 178 of these patients received insulin treatment either alone (86%) or in combination with other OADs (mostly sulfonylureas). Mean age was 64 years, 48% were female, and the mean duration of diabetes was 19 years. Table 1 demonstrates that mean HbA_{1c} was reduced in vildagliptin-treated patients by -0.87% from a baseline of 7.7%, with the placebo-subtracted reduction being -0.59% ($p<0.0001$). Hypoglycemia overall and severe hypoglycemic events were reported at a similar rate in vildagliptin and placebo patients (19% vs 14% and 2% vs 3%, respectively) in spite of considerably greater HbA_{1c} reduction in the vildagliptin group. The overall incidences of AEs and SAEs were similar for vildagliptin and placebo (79% vs. 77% and 19% and 24%, respectively).

Conclusion: The mean HbA_{1c} reduction of 0.87% (0.59% decrease vs. placebo) from a baseline of 7.7% in insulin requiring patients with longstanding T2DM and severe renal impairment is consistent with the drops in HbA_{1c} that have been reported previously in vildagliptin-treated patients with much more recent onset of diabetes. Vildagliptin treatment in combination with insulin in patients with severe renal impairment appears to be as efficacious as in patients with less impairment in beta-cell function.

Long-term efficacy and safety of linagliptin in patients with type 2 diabetes and severe renal impairment

J. Newman¹, J.B. McGill², S. Patel³, C. Friedrich⁴, C. Sauce⁵, H.-J. Woerle⁶,
¹Boehringer Ingelheim, Ridgefield, USA, ²Washington University in St. Louis, St. Louis, USA, ³Boehringer Ingelheim, Bracknell, UK, ⁴Boehringer Ingelheim, Biberach, Germany, ⁵Boehringer Ingelheim, Reims, France, ⁶Boehringer Ingelheim, Ingelheim, Germany.

Background and aims: Renal impairment (RI) is a common complication of type 2 diabetes mellitus (T2DM). Linagliptin is a novel dipeptidyl peptidase-4 (DPP-4) inhibitor with unique pharmacological characteristics that allow the treatment of T2DM patients without dose adjustment for any degree of RI. This 52-week, randomised, double-blind, placebo (PBO)-controlled trial conducted at 53 centres in 6 countries evaluated the efficacy and safety of linagliptin in patients with T2DM and severe RI. The primary endpoint, HbA_{1c} change from baseline at week 12, was reported previously. Here we present the results of the full 52-week period.

Materials and methods: Patients with T2DM and severe RI (HbA_{1c} 7.0–10.0%; estimated glomerular filtration rate [eGFR] by MDRD formula <30 mL/min/1.73 m²) were randomised with equal probability to either linagliptin 5 mg once daily (n=68) or PBO (n=65), in addition to pre-existing glucose-lowering therapy. Background therapy doses could be adjusted only after week 12, according to glucose parameters.

Results: Mean values (±SD) for baseline age, HbA_{1c}, and eGFR were 64±10 years, 8.2±1.0%, and 24±7 mL/min/1.73 m², respectively. Diabetes duration was >5 years in 96% of patients and 80% were treated with insulin (alone or in combination). In the comparison vs PBO, the adjusted mean change in HbA_{1c} from baseline at week 52 was -0.72% (95% CI -1.03, -0.41; p<0.0001), confirming the superiority of linagliptin over PBO as demonstrated at week 12. HbA_{1c} values for the 12–52 week period showed that reductions were maintained throughout the study (Figure). Rates for any adverse event (AE) and serious AEs were similar with linagliptin (94.1% and 36.8%, respectively) and PBO (92.3% and 41.5%). The incidence of overall hypoglycaemia was higher with linagliptin (63.2%) than in the PBO group (49.2%); however, this difference was based on higher rates of mild, asymptomatic hypoglycaemic episodes and there was no difference in severe hypoglycaemic events (3 each). Renal function remained stable throughout the study in both treatment arms, and numbers of cardiovascular deaths in this high-risk population were similarly low (linagliptin, n=2 [2.9%]; PBO, n=3 [4.6%]).

Conclusion: Linagliptin, as a single dose not requiring adjustment, is an effective and durable treatment option for controlling blood glucose concentrations in T2DM patients with severe RI without an increased risk for clinically meaningful hypoglycaemia in this vulnerable patient population.

Reductions in HbA_{1c} and the incidence of hypoglycaemic episodes are not affected by renal impairment in patients with type 2 diabetes treated with liraglutide

S. Gough¹, B. Feldt-Rasmussen², J. Davidson³, S. Furber⁴, M. Donsmark⁴, D. Scott⁵

¹OCDEM, Oxford, UK, ²Rigshospitalet, Copenhagen, Denmark, ³UT Southwestern Medical School, Dallas, USA, ⁴Novo Nordisk, Bagsvaerd, Denmark, ⁵Clinical Research Development Associates, Springfield Gardens, USA.

Background and aims: Impaired renal function is often observed in people with type 2 diabetes (T2D). Clinical studies have previously shown that the once-daily human GLP-1 analogue, liraglutide, is not excreted in urine, but rather is completely degraded *in vivo* by DPP-4 and neutral endopeptidases. This meta-analysis investigated the efficacy and safety of liraglutide in patients with T2D to establish if treatment effectiveness is compromised in individuals with mild and moderate renal impairment (RI).

Materials and methods: A meta-analysis of 7 clinical trials in the liraglutide development programme was performed using data from 0–26 wks to assess changes in HbA_{1c} and serum creatinine (SC) from baseline and incidence of hypoglycaemia during liraglutide treatment (1.2 and 1.8 mg) in patients with normal renal function, compared with those with mild and moderate RI. Renal function was determined by estimated creatinine clearance [eCrCl] using the Cockcroft-Gault equation and defined as normal, eCrCl ≥ 90 mL/min; mild: eCrCl < 90 mL/min or moderately impaired, eCrCl < 60 mL/min; all corrected to a standard body surface area of 1.73 m². Changes in HbA_{1c} and SC were analysed using ANCOVA with trial treatment with or without metformin, and interaction between treatment (placebo, 1.2 and 1.8 mg liraglutide) and baseline eCrCl category as fixed effects and baseline HbA_{1c} or SC respectively as covariates.

Results: Over 26 wks, patients receiving either dose of liraglutide had greater HbA_{1c} reductions than patients receiving placebo. HbA_{1c} reductions were similar in patients with mild and moderate RI vs those with normal renal function (Fig), with no significant differences in HbA_{1c} reductions observed between groups. Even in patients with the greatest baseline RI (moderate group), reduction in HbA_{1c} with liraglutide was not compromised vs patients with normal renal function. The proportion of patients experiencing major hypoglycaemic episodes in this study was low (0–0.2%). Minor hypoglycaemic episodes appeared lower in patients with mild or moderate RI compared to those with normal renal function; a trend observed in all treatment groups. Changes in SC were small (-4.82 to 6.08 μmol/L). Interestingly, for moderate RI, SC was significantly improved in patients treated with 1.8 mg liraglutide (-4.82 μmol/L) vs placebo (6.08 μmol/L) (treatment difference: -10.90 μmol/L, p=0.0008).

Conclusion: In patients with T2D with concomitant mild to moderate RI, the glycaemic efficacy of liraglutide is similar to those with normal renal function. In addition, liraglutide treatment in patients with RI is not associated with an increased risk of hypoglycaemia. Liraglutide appears to be an effective and well-tolerated antidiabetic treatment in patients with T2D who also have mild or moderate RI.

Clinical Trial Registration Number: NCT00318422; NCT00318461; NCT00294723; NCT00333151; NCT00331851; NCT00518882; NCT00700817

Changes in kidney function and renal adverse events in clinical trials comparing exenatide once weekly and exenatide twice daily

P.W. Anderson¹, C. Brown², D. Lee², C.R. Heilmann¹, B.J. Hoogwerf¹, J.L. Scism-Bacon³, K. Tuttle⁴;

¹Eli Lilly and Company, Indianapolis, ²Amylin Pharmaceuticals, Inc, San Diego, ³i3Statprobe, Indianapolis, ⁴Sacred Heart Medical Center, Spokane, USA.

Background and aims: Exenatide twice daily (EBID) 5 mcg or 10 mcg is a GLP-1 receptor agonist indicated in the European Union for the treatment of type 2 diabetes in combination with certain oral medications in patients with inadequate glycemic control. Data from 6 EBID, placebo-controlled trials do not show deleterious changes in kidney function in patients with near-normal estimated glomerular filtration rate (eGFR) treated with exenatide. This post-hoc analysis assessed changes in kidney function in patients treated with exenatide once weekly (EQW) 2 mg vs. EBID 10 mcg in 2 randomized, open-label clinical trials of 24–30 weeks.

Materials and methods: Subjects had sub-optimal glucose control (HbA_{1c} 7.1%–11.0%), had a BMI of 25–45 kg/m², and were treated with diet and exercise alone or with metformin, TZD, sulfonylurea, or combinations of these at baseline. Key exclusion criteria included a diagnosis of kidney disease or serum creatinine (SCr) > 1.4 mg/dL (female), > 1.6 mg/dL (male). Potential clinically important (PCI) renal function values for blood urea nitrogen (BUN) and SCr were defined as: BUN > 45 mg/dL; SCr > 1.6 mg/dL (male), > 1.4 mg/dL (female). Modified Modification of Diet in Renal Disease (MDRD) and Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations were used to calculate the eGFR, with main analyses performed on subjects with baseline eGFR < 120 (N=518 using MDRD; N=532 using CKD-EPI).

Results: Baseline eGFR (mean±SD) was similar between groups (MDRD: EQW 79±17 mL/min, EBID 79±17 mL/min; CKD-EPI: EQW 86±17 mL/min, EBID 87±18 mL/min), as was the annualized change in eGFR from baseline to endpoint (LSMean±SE) (MDRD: EQW -6.1±2.4 mL/min, EBID -4.6±2.5 mL/min, p=0.674; CKD-EPI: EQW -5.2±2.4 mL/min, EBID -6.0±2.5 mL/min, p=0.816). There were no clinically meaningful changes from baseline to endpoint in BUN (LSMean±SE) for patients with eGFR < 120 by the MDRD equation (EQW -0.3±0.1 mg/dL, EBID -0.1±0.1 mg/dL) or for patients with eGFR < 120 by the CKD-EPI equation (EQW -0.2±0.1 mg/dL, EBID -0.1±0.1 mg/dL) or in SCr (MDRD: EQW 0.02±0.03 mg/dL, EBID 0.06±0.03 mg/dL; CKD-EPI: EQW 0.02±0.03, EBID 0.06±0.03 mg/dL) for either group. The proportion of subjects with elevated BUN (EQW 7%, EBID 4%, p=0.163) or elevated SCr (EQW 4%, EBID 4%, p=0.691) values at endpoint were similar between groups. The proportions of subjects with PCI elevated BUN (EQW 0%, EBID < 1%, p=0.312) or PCI elevated SCr (EQW 1%, EBID 1%, p=0.927)

values at endpoint were similar between groups. Comparison of the percentage of subjects with decreased or increased kidney function (defined as moving up or down CKD stage), based on the MDRD equation, showed no differences between EQW and EBID (decreased 14% vs 16%, no change 78% vs 77%, increased 8% vs 8%, p=0.951), comparing increased vs. decreased function between treatment groups. Similar results were obtained for EQW vs EBID, based on the CKD-EPI equation (decreased 15% vs 19%, no change 75% vs 72%, increased 10% vs 8%, p=0.202). There was no difference between groups in the incidence of renal treatment-emergent adverse events (TEAEs) (EQW 3%, EBID 3%, p=0.757).

Conclusion: This analysis does not show clinically meaningful differences between patients treated with EQW and EBID with regard to kidney function or renal TEAEs in subjects with normal or near-normal eGFR.

DPP-4 inhibition: a new approach for the treatment of uraemic cardiomyopathy

L. Chaykovska¹, K. von Websky¹, S. Heiden¹, J. Rahnenführer¹, T. Klein², B. Hoher¹;

¹Center for Cardiovascular Research, Institute for Pharmacology and Toxicology, Charité, Berlin, ²Boehringer Ingelheim, Biberach, Germany.

Background and aims: Uraemic cardiomyopathy contributes substantially to morbidity and mortality of patients with chronic kidney disease, which is in turn also a frequent complication of type 2 diabetes. Glucagon-like peptide-1 (GLP-1) may improve cardiac function and GLP-1 is mainly degraded by dipeptidyl peptidase-4 (DPP-4). Linagliptin is the only DPP-4 inhibitor that can be used clinically at all stages of renal insufficiency without dose adjustment. We investigated linagliptin in a rat model of chronic renal insufficiency (5/6 nephrectomy [5/6N]).

Materials and methods: Eight weeks after 5/6N or sham surgery, rats were treated orally with 3.3 mg/kg linagliptin or vehicle for 4 days, and, subsequently, plasma was sampled for 72 h for quantification of DPP-4 activity and GLP-1 levels. At the end of the study, heart tissue was harvested for mRNA analyses.

Results: 5/6N caused a significant (p < 0.001) decrease in GFR measured by creatinine clearance (sham: 2510±210 mL/24 h; 5/6N: 1665±104.3 mL/24 h) and increased cystatin C levels (sham: 700±35.7 ng/mL; 5/6N: 1434±77.6 ng/mL). DPP-4 activity was significantly reduced at all time points with no difference between sham or 5/6N animals. In contrast, active GLP-1 levels were significantly increased in 5/6N animals, as measured by the maximum plasma concentration (C_{max}; 5/6N: 6.36±2.58 pg/mL vs sham: 3.91±1.86 pg/mL; p < 0.001) and AUC_(0-72h) (5/6N: 201 pg·h/mL vs sham: 114 pg·h/mL; p < 0.001). The mRNA levels of cardiac fibrosis markers such as TGF-β, tissue inhibitor of matrix metalloproteinase 1 (TIMP-1) and collagens 1a1 and 3a1 as well as markers of left ventricular dysfunction such as brain natriuretic peptide (BNP) were all significantly increased in 5/6N versus sham animals and consequently reduced or even normalized by linagliptin treatment (all p < 0.05; Table).

Conclusion: Linagliptin increased the AUC of GLP-1 approximately two-fold in a rat model of renal failure, and decreased gene expression of BNP, a marker of left ventricular dysfunction, as well as markers of cardiac fibrosis (TGF-β, TIMP-1, Col 1a1 and Col 3a1) in hearts of uraemic rats. These effects may support the use of linagliptin in uraemic cardiomyopathy; however, further studies are necessary to evaluate if the observed anti-fibrotic effects are caused by GLP-1 levels or are independent of the incretin pathway.

Ratio of changes in mRNA for treated versus control animals			
Marker	Sham	5/6N	5/6N + Linagliptin
TGF-β	0.83±0.02	0.93±0.05	0.80±0.10
TIMP-1	0.92±0.04	1.39±0.17	0.72±0.20
Col1a1	0.61±0.06	0.83±0.03	0.76±0.05

The dipeptidyl peptidase-4 inhibitor vildagliptin does not affect ex vivo cytokine response nor T-lymphocyte function in patients with type 2 diabetes mellitusP.C.M. van Poppel¹, M.S. Gresnigt², P. Smits³, M.G. Netea¹, C.J. Tack¹¹Department of Internal Medicine, ²Nijmegen Institute for Infection, Inflammation and Immunity (N4i), ³Department of Pharmacology and Toxicology, Radboud University Nijmegen Medical Centre, Netherlands.

Background and aims: Dipeptidyl peptidase-4 (DPP-4), a key player in the degradation of incretin hormones and therefore a therapeutic target in type 2 diabetes, is also expressed on immune cells. DPP-4 inhibition may thus alter immune response, which could translate into susceptibility to infections. Some reports indeed suggest that the use of DPP-4 inhibitors is associated with an increased incidence of infections. The aim of this study, a substudy of a trial assessing the effect of vildagliptin on endothelial function, was to assess the effect of treatment with the DPP-4 inhibitor vildagliptin on both the innate immune production of cytokines and T-helper responses of patients with diabetes mellitus.

Materials and methods: Patients with type 2 diabetes on oral treatment (age 35–75 yrs, HbA1c < 8.0%) were treated with vildagliptin or acarbose for 4 weeks, in a randomized cross-over trial. At the end of each treatment period, peripheral blood mononuclear cells (PBMCs) were isolated and ex vivo stimulated with a broad spectrum of pattern recognition receptor agonists. In addition, T-cell function and activation was tested.

Results: The production of the proinflammatory cytokines IL-1 β , TNF- α and IL-6 by monocytes after 24h stimulation with LPS, Pam₃Cys, β -glucan, Pam₃Cys + β -glucan, heat killed *S. aureus* and *C. albicans* yeasts was not affected by vildagliptin. IL-1 β levels were 3884 \pm 389, 2052 \pm 474, 47 \pm 7, 4061 \pm 448, 1834 \pm 374 and 1425 \pm 184 pg/ml for vildagliptin and 4337 \pm 663, 1971 \pm 493, 40 \pm 1.3, 4027 \pm 462, 2003 \pm 370 and 1533 \pm 231 pg/ml for acarbose treatment, P=NS for all comparisons. Similar results were found for TNF- α and IL-6 production. Neither production of the T-cell cytokines IL-10, IFN- γ and IL-17 nor direct T-cell activation was affected by vildagliptin treatment (Fig 1). Finally, the relative increase of mRNA levels of T-cell lineage specific transcription factors T-bet, GATA-3 and FoxP3, did not differ between both treatment periods. (Fig 1) There were no carry over effects.

Conclusion: These data show that treatment of patients with type 2 diabetes mellitus with vildagliptin does not result in a significant modulation of both monocyte and T-cell-derived cytokine responses. These results, obtained in a relevant population, suggest that DPP-4 inhibition does not affect immune function. Figure 1. A Levels of the T-cell derived cytokines IFN- γ , Th17 and

IL-10 in the culture supernatants of PBMCs which stimulated after either vildagliptin (grey bars) or acarbose treatment (black bars). B Relative upregulation of mRNA transcription of T-cell lineage specific factors after stimulation with HK C. Albicans compared to unstimulated PBMCs.

Trends in the characteristics of patients prescribed sitagliptin and other oral antihyperglycaemic agents over time in a large U.S. claims databaseT.D. Kou¹, K.G. Brodovicz¹, C.M. Alexander², E.A. O'Neill³, S. Engel⁴, C.J. Girman¹¹Epidemiology, Merck, North Wales, ²Global Medical Affairs, Merck, North Wales, ³Global Scientific and Medical Publications, Merck, Rahway, ⁴Clinical Research - Metabolism, Merck, Rahway, USA.

Background and aims: Differences in baseline demographic and clinical characteristics of patients initiating new therapy can introduce bias into comparative effectiveness/safety analyses. This study explored trends in the baseline characteristics of patients with type 2 diabetes (T2D) initiating sitagliptin, a DPP-4 inhibitor introduced in the U.S. in 2006, or other oral antihyperglycemic agents (OHA) between 2006 and April 2010 in a large U.S. insurance claims database.

Materials and methods: Using the United HealthCare I3 LabRx database, we identified a cohort of T2D patients with at least 1 new prescription for sitagliptin or other OHA between 1Jan2006 to 30Apr2010. Patients age 25–64 years receiving a new prescription in 2006–2007 were compared to patients receiving a new prescription in 2008–2010. Multivariate logistic regression analyses adjusting for age, sex, treatment complexity (monotherapy, dual, triple therapy), incident or prevalent T2D, comorbidities in prior 12 months, and time period were used to estimate odds ratios (OR) with 95% CI.

Results: Between 2006–2007, 11,550 patients filled a new prescription for sitagliptin and 106,122 filled a new prescription for another OHA. Between 2008–2010, 31,085 and 129,117 patients filled new prescriptions for sitagliptin or another OHA, respectively. Compared to new users of other OHAs, new sitagliptin users were older, more were male, less were newly diagnosed with T2D, and more were on combination therapy at the start of therapy (table). Comorbidities were consistently higher for new sitagliptin users across most of the comorbidities assessed, including blindness/macular edema/retinopathy, heart failure, hypertension, myocardial infarction, neuropathy, peripheral vascular disease, proteinuria, and renal failure. These differences were consistent across periods. After adjustment for covariates in the table, new sitagliptin users remained older and more likely to use combination therapy. While age and combination therapy were strong confounders, the prevalence of several comorbidities remained significantly higher in new sitagliptin users at the start of therapy (blindness/macular edema/retinopathy, hypertension, proteinuria).

Conclusion: Based on this analysis of a large cohort in a U.S. claims database, new sitagliptin users consistently had a higher proportion of several important comorbidities compared to new users of other OHAs. These differences in baseline characteristics were observed not only in the first 2 years post-approval but persisted 2–4 years post-approval. This has significant implications for pharmacoepidemiology observational studies in electronic medical record or claims databases and supports the need for control of channeling bias in such studies.

Saxagliptin vs glipizide as add-on therapy to metformin in patients with type 2 diabetes: a 2-year assessment of HbA_{1c}, hypoglycaemia, and weight gain in a randomised, double-blind study

E. Allen, N. Berglind;

Bristol-Myers Squibb, Princeton, USA.

Background and aims: Hypoglycemia and fears of hypoglycemia hinder glycaemic goal achievement and may delay intensification of antidiabetic therapy. Hypoglycemia and weight gain are known risks of sulfonylurea therapy, and its use may impede the safe and effective management of type 2 diabetes (T2D). In clinical practice, it is important to achieve glycaemic goals without weight gain or episodes of hypoglycemia. The dipeptidyl peptidase-4 inhibitor saxagliptin (SAXA) potentiates insulin secretion in a glucose-dependent manner and is associated with a low incidence of hypoglycemia and is weight neutral. A post hoc analysis was conducted to explore the difference in hypoglycemic events and weight gain in patients with T2D reaching HbA_{1c} goals after treatment with SAXA or glipizide (GLIP) as add-on to metformin (MET).

Materials and methods: In a multicenter, randomized, double-blind, parallel-group study, adults with HbA_{1c} >6.5% and ≤10% were given SAXA 5 mg/d (n=428) or GLIP titrated from 5–20 mg/d (n=430) as an add-on to MET for 52 weeks. Patients were treated for an additional 52 weeks in a prospective, blinded extension period, yielding a total observation period of 104 weeks. Assessment at 104 weeks showed that SAXA was similar to GLIP in lowering HbA_{1c} when added to MET and was well tolerated. The proportion of patients with adverse events (excluding hypoglycemia) in the 2 treatment groups was similar. A post hoc analysis examined 1) the difference in the frequency of hypoglycemic events between the SAXA and GLIP groups by baseline HbA_{1c} categorical groupings using a Kaplan-Meier analysis and 2) the proportion of patients with baseline HbA_{1c} ≥7% who had HbA_{1c} <7% observed at week 104 without hypoglycemia or weight gain of ≥2% (last observation carried forward).

Results: Fewer SAXA-treated patients (3.5%) than GLIP-treated patients (38.4%) had ≥1 hypoglycemic event through week 104. Hypoglycemic events occurred earlier and more frequently in patients treated with GLIP compared with SAXA in all subgroups of baseline HbA_{1c}. In both treatment groups, the number of patients with hypoglycemic events was higher with progression from higher to lower baseline HbA_{1c}. No SAXA-treated patients who had baseline HbA_{1c} ≥9% had a hypoglycemic event. More patients treated with SAXA had no weight gain during treatment (Table). Although approximately the same proportion of patients in each treatment group achieved HbA_{1c} <7%, more patients treated with SAXA vs GLIP did so without experiencing hypoglycemia, with weight gain <2%, or both (Table).

Conclusion: Regardless of baseline HbA_{1c}, fewer patients experience hypoglycemic events with the addition of SAXA to MET compared with the addition of GLIP. The difference is more pronounced at lower baseline HbA_{1c} levels, highlighting the safety of SAXA in patients with lower baseline HbA_{1c} levels. Compared with addition of GLIP to MET, addition of SAXA to MET resulted in more patients achieving glycaemic control without hypoglycemia and weight gain over a 2-year period.

Endpoint at Week 104	SAXA 5 mg + MET n=428*	GLIP + MET n=430*
Patients included in analysis [†] , n	324	322
Weight gain <2%, n (%)	266 (82.1)	190 (59.0)
HbA _{1c} <7%, n (%)	75 (23.1)	73 (22.7)
HbA _{1c} <7% and no hypoglycemia, n (%)	72 (22.2)	43 (13.4)
HbA _{1c} <7% and weight gain <2%, n (%)	65 (20.1)	47 (14.6)
HbA _{1c} <7%, no hypoglycemia, and weight gain <2%, n (%)	63 (19.4)	28 (8.7)

*Total number of patients in each group.

[†]Patients in this analysis had baseline HbA_{1c} ≥7% and ≥1 post-baseline weight measurement; patients were required to have an HbA_{1c} value <7% in the week 104 analysis window in order to have achieved goal; weight data were last observation carried forward.

Effects of saxagliptin added to sub-maximal doses of metformin compared with dose escalation of metformin in type 2 diabetes: results from the PROMPT study

M.P. Hermans¹, T. Delibasi², I. Farmer³, L. Lohm⁴, P.-M. Piatti⁵, E. Malvolti⁶, S. Jörgens⁷, B. Charbonnel⁸;

¹Cliniques Universitaires Saint-Luc, Brussels, Belgium, ²Ankara Diskapi Training and Research Hospital, Ankara, Turkey, ³The Surgery, Ashford, UK,

⁴AstraZeneca, Södertälje, Sweden, ⁵San Raffaele Scientific Institute, Milan, Italy, ⁶Bristol-Myers Squibb, Paris, France, ⁷ClinResearch GmbH, Köln, Germany, ⁸Clinique d'Endocrinologie, Nantes, France.

Background and aims: High doses of metformin (MET) are often associated with an increased incidence of gastrointestinal (GI) symptoms which may lead to poor patient (pt) compliance and physician reluctance to increase the dose. The PROMPT study aimed to compare the efficacy and tolerability of 2 different treatment intensification strategies, either adding saxagliptin (SAXA) or uptitrating MET monotherapy (MET-UP) in pts with type 2 diabetes (T2D) and inadequate glycaemic control on a sub-maximal dose of MET 1.5 g/d.

Materials and methods: In this pan-European (Belgium, France, Germany, Italy, Spain, Turkey, UK), double-blind, parallel-group study, pts with T2D on MET monotherapy (1.5–1.7 g/d; HbA_{1c} ≥7–≤10% at study entry) were randomised to receive for 24 weeks, on a standardised, fixed dose of MET 1.5 g/d, either add-on SAXA 5 mg/d (SAXA+MET) or a 2-step MET uptitration, to a maximum dose of 2.5 g/d (MET-UP). GI symptoms were assessed using the 5-item validated Digestive Health Status Index (DHSI). Pts previously intolerant or non-compliant to MET >1.5 g/d were excluded.

Results: 286 pts ≥18 y were randomised. Mean baseline HbA_{1c} values (±SD) were 7.7±0.8% and 7.8±0.8% in the SAXA+MET and MET-UP groups, respectively. After 24 weeks, reductions from baseline in HbA_{1c} were (adjusted mean) -0.47% for SAXA+MET and -0.38% for MET-UP; mean (95% CI) difference in treatment effect, -0.10% (-0.26%, 0.07%); p=0.26. Discontinuations due to lack of efficacy were 10.9% for SAXA+MET vs 16.5% for MET-UP. The overall incidence of adverse events (AEs) was 51.0% for SAXA+MET vs 43.9% for MET-UP. The incidence of any hypoglycaemic event was 6.8% in the SAXA+MET group vs 2.2% in the MET-UP group, although the number of pts with a confirmed hypoglycaemic event (<3 mM) did not differ between the 2 groups. The 2 most common (>5%) AEs were diarrhoea (6.1% vs 12.2%) and nasopharyngitis (5.4% vs 1.4%) in the SAXA+MET and MET-UP groups, respectively. Exploratory analyses of the DHSI questionnaire showed differences (mean ±SE) in the diarrhoea predominant score (+0.8±1.7 vs +7.9±1.7; p=0.003) and dysmotility score (-0.5±0.8 vs +1.9±0.8; p=0.03) in the SAXA+MET and MET-UP groups, respectively, demonstrating the GI inconvenience of uptitrating MET in this pt group. No significant differences were reported for the other 3 DHSI items. Mean body weight (±SD) decreased in both treatment groups; -1.1±3.5 kg in pts treated with SAXA+MET and -1.6±2.7 kg in the MET-UP group.

Conclusion: In pts with T2D inadequately controlled on sub-maximal doses of MET and with no previously reported MET-related tolerability issues, addition of SAXA 5 mg/d to MET monotherapy was well tolerated. The HbA_{1c} reductions observed in the SAXA+MET and the MET-UP groups were not statistically different but there was an increase in GI side effects with the MET-UP intensification strategy. These data suggest that the SAXA add-on treatment strategy is a suitable alternative to MET uptitration in pts with T2D not well controlled on sub-maximal MET monotherapy.

Clinical characteristics and sustained glycaemic control: a 76-week, randomised, double-blind study of saxagliptin + metformin in treatment-naïve patients with type 2 diabetes

R. Frederich¹, P. Öhman², N. Berglind¹, E. Allen¹;

¹Bristol-Myers Squibb, Princeton, ²AstraZeneca, Wilmington, USA.

Background and aims: The efficacy of the dipeptidyl peptidase-4 inhibitor saxagliptin (SAXA) was evaluated as initial therapy with metformin (MET) in treatment-naïve patients with type 2 diabetes (T2D). After 24 weeks of therapy, significantly more patients achieved glycaemic response (HbA_{1c} <7%) with SAXA + MET combination therapy (SAXA 5 mg + MET, 60.3%; SAXA 10 mg + MET, 59.7%; P<0.0001) than with SAXA 10 mg alone (32.2%) or

MET alone (41.1%). SAXA was well tolerated. Similar proportions of patients in each group had adverse events. Durability of glycemic response is important for long-term T2D treatment. We conducted a post hoc analysis to 1) compare sustained glycemic response (SGR, defined as $HbA_{1c} < 7\%$ observed at both weeks 24 and 76; patients not meeting criteria at either time were treated as failures) with SAXA + MET vs MET monotherapy; 2) identify relationships between achieving SGR and key baseline (BL) characteristics; 3) determine whether there was a differential effect for SAXA + MET vs MET monotherapy.

Materials and methods: In this phase 3, double-blind, parallel-group trial, 1306 patients with T2D inadequately controlled (HbA_{1c} 8–12%) with diet and exercise were randomly assigned 1:1:1 to receive oral SAXA 5 mg + MET, SAXA 10 mg + MET, SAXA 10 mg, or MET. Differences in the proportion of patients with SGR were presented as percentages with exact 95% CI. Logistic regression models included treatment, select BL covariates (Table), and treatment*BL covariate interaction.

Results: BL characteristics were generally well balanced among randomized groups (mean age, 52 y; T2D duration, 1.7 y; BL HbA_{1c} , 9.5%). A greater proportion of patients treated with SAXA 5 mg + MET (38.1%) and SAXA 10 mg + MET (36.8%) than with MET alone (22.0%) had SGR (difference SAXA 5 mg + MET vs MET: 16.2%, 95% CI, 9.1–23.1; difference SAXA 10 mg + MET vs MET: 14.9%, 95% CI, 7.9–21.8). The greater proportion of patients achieving SGR with SAXA + MET than with MET alone was not differentially affected by demographic or BL patient characteristics. For BL clinical characteristics, the chance of achieving SGR in all treatment groups was improved with increased BL homeostasis model assessment 2 β -cell function (HOMA-2B), insulin AUC, C-peptide AUC, or age; reduced by increased BL HbA_{1c} or postprandial glucose AUC; numerically reduced in women; and not clearly associated with BMI (Table). Increased glucagon AUC and duration of T2D reduced the chance of SGR with MET, but not with SAXA + MET.

Conclusion: Initial therapy with SAXA + MET consistently resulted in more patients achieving SGR vs MET monotherapy over a 76-week period in treatment-naïve adults with inadequately controlled T2D, regardless of BL characteristics. The BL clinical characteristics associated with SGR were generally similar among treatment subgroups. These results suggest that SGR may be more likely when therapy is begun at a less severe stage of deterioration in glycemic control.

Baseline or Demographic Characteristic	Odds Ratio for Achieving SGR (95% CI)		
	SAXA 5 mg + MET n=320	SAXA 10 mg + MET n=323	MET n=328

Metformin/saxagliptin combination therapy can replace insulin therapy in patients with type 2 diabetes: interim results from the SAXAswitch study

A.H. Pfützner¹, A. Schorsch², T. Forst¹, A. Pfützner¹, SAXAswitch Study Group;

¹R&D, IKFE Institute for Clinical Research and Development, ²IKFE-CRO, Mainz, Germany.

Background and aims: Type 2 diabetes is a complex disease with various phenotypes, as patients suffer from vascular and metabolic insulin resist-

ance and β -cell dysfunction with different degrees of severity. We previously showed that patients on insulin treatment with predominant insulin resistance can be switched back to oral treatment with insulin sensitizers. In this study, we investigate whether in patients with residual β -cell function (low proinsulin and normal C-peptide levels) an oral combination treatment with saxagliptin and metformin (Saxa+Met) can also replace an existing insulin therapy

Materials and methods: The participants in this study had to be on insulin therapy for more than one year and good control ($HbA_{1c} < 7.5\%$). They were subjected to a 1:2 randomization to stay on insulin (n = 37; 19 women, 18 men, age: 63 ± 8 yrs., disease duration: 11.0 ± 5.3 yrs., BMI: 33.3 ± 6.4 kg/m², HbA_{1c} : 6.8 ± 0.5 %) or to switch to an oral combination therapy with 2x 850 mg of metformin and 5 mg saxagliptin (n = 72, 31 women, 41 men, age: 62 ± 9 yrs., disease duration: 11.9 ± 7.4 yrs., BMI: 33.9 ± 5.6 kg/m², HbA_{1c} : 6.8 ± 0.5 %) for an observation period of 6 months. In case of worsening of glycemic control (HbA_{1c} increase > 0.4 %), pioglitazone was provided as first rescue drug (+Pio), and insulin glargine served as 2nd rescue drug (+Glarg).

Results: This completer analysis was performed with the 92/109 patients (84 %), who had completed the trial with stable glycemic control. Only 3/37 patients had dropped out in the insulin group for protocol violations (= 92 % completers,) and 14/72 patients stopped the study prematurely in the oral treatment group for reasons of HbA_{1c} -increase, adverse events, or patient decision (81 % completers). From the 58 completers on oral therapy, 21 were finally on Saxa+Met (36 %, HbA_{1c} at endpoint: 6.6 ± 0.4 %, Change in BMI: -1.2 ± 0.3 kg/m²), 19 were on Saxa+Met+Pio (33 %, 6.8 ± 0.5 %, -1.1 ± 0.2 kg/m²), and 18 were on Saxa+Met+Pio+Glarg (31 %, 7.2 ± 0.6 %, Change in BMI: -1.9 ± 0.4 kg/m²). There were no differences regarding type and severity of adverse events between the two treatment arms.

Conclusion: A combination of modern oral drugs addressing the underlying disease pathophysiology may allow a successful switch back from insulin treatment to oral combination therapy in patients with residual β -cell function. Further analysis will now be performed to identify laboratory biomarkers able to indicate the severity of β -cell dysfunction and with predictive value for such a successful switch from insulin to oral anti-diabetic drug combinations including saxagliptin.

Efficacy and safety of 5 mg daily dosing regimens with linagliptin in patients with type 2 diabetes inadequately controlled on metformin

E. Rafeiro¹, S.A. Ross², T. Meinicke³, R. Toorawa⁴, H.-J. Woerle⁵;

¹Boehringer Ingelheim, Burlington, Canada, ²LMC Endocrinology Centres, University of Calgary, Canada, ³Boehringer Ingelheim, Biberach, Germany, ⁴Boehringer Ingelheim, Bracknell, UK, ⁵Boehringer Ingelheim, Ingelheim, Germany.

Background and aims: Glycaemic control in patients with type 2 diabetes mellitus (T2DM) can be difficult using monotherapies such as metformin as target blood glucose levels are often not achieved. Addition of further agents, such as the dipeptidyl peptidase-4 (DPP-4) inhibitor linagliptin, to existing therapy has been shown to improve glycaemic control. This study was conducted to evaluate whether twice-daily (bid) dosing with linagliptin 2.5 mg would achieve comparable efficacy and safety to once-daily (qd) linagliptin 5 mg (ie, the same total daily dose) when given on top of metformin bid in patients with inadequate glycaemic control.

Materials and methods: Individuals (HbA_{1c} 7–10%) were randomized (5:5:1) to receive linagliptin 2.5 mg bid or 5 mg qd, or placebo for 12 weeks in addition to background metformin bid (≥ 1500 mg/day or maximally tolerated dose). The primary endpoint was change from baseline in HbA_{1c} after 12 weeks, while secondary endpoints included HbA_{1c} lowering of $\geq 0.5\%$, and change from baseline in fasting plasma glucose (FPG) after 12 weeks. The efficacy of linagliptin 2.5 mg bid versus 5 mg qd was compared using a pre-specified non-inferiority margin (95% CI within +0.35% HbA_{1c}).

Results: In total, 491 patients with a mean baseline HbA_{1c} 8.0% were randomized. After 12 weeks, linagliptin 2.5 mg bid and 5 mg qd significantly reduced HbA_{1c} (placebo-adjusted changes -0.74% [95% CI -0.97 , -0.52] and -0.80% [95% CI -1.02 , -0.58]; both $p < 0.0001$; Figure). Efficacy was comparable for the two linagliptin regimens with a difference in HbA_{1c} (0.06% [95% CI -0.07 , 0.19]) that was within the predefined noninferiority margin. FPG was also reduced versus placebo (2.5 mg bid -13.7 mg/dL [95% CI -22.7 , -4.7]; $p = 0.0029$; 5 mg qd -17.8 mg/dL [95% CI -26.7 , -8.8]; $p < 0.0001$). The

proportion of patients achieving HbA_{1c} reductions of $\geq 0.5\%$ was 55.1% with linagliptin 2.5 mg bid, 59.7% with 5 mg qd and 16.3% with placebo. Rates of adverse events (AEs) were similar with linagliptin 2.5 mg bid, 5 mg qd and placebo (43.0%, 34.8% and 38.6%, respectively). Most AEs were mild-to-moderate in intensity and few were deemed related to study medication in any group. Hypoglycaemic events were rare (3.1% for linagliptin 2.5 mg bid, 0.9% for 5 mg qd and 2.3% for placebo) and there were no cases of severe hypoglycaemia.

Conclusion: Both 5 mg daily dosing regimens of linagliptin provided meaningful efficacy in patients inadequately controlled with metformin monotherapy. Linagliptin achieved HbA_{1c} reductions of up to 0.8% after 12 weeks of treatment in this study.

Placebo-corrected adjusted mean (SE) changes in HbA_{1c} from baseline after 12 weeks with linagliptin 2.5 mg bid or 5 mg qd (FAS [LOCF])

*P<0.0001 vs placebo

The 12-week change from baseline in the placebo group (n=43) was +0.28% (SE 0.11) from a mean baseline HbA_{1c} 7.92%

Linagliptin improves glycaemic control independently of diabetes duration and insulin resistance in patients with type 2 diabetes

S. Patel¹, S. Weber², A. Emsw², M. von Eynatten², H.-J. Woerle²;

¹Boehringer Ingelheim, Bracknell, UK, ²Boehringer Ingelheim, Ingelheim, Germany.

Background and aims: Three randomised, double-blinded, placebo-controlled, phase 3 trials for the dipeptidyl peptidase-4 (DPP-4) inhibitor linagliptin examined safety and efficacy of glycaemic control as monotherapy, as add-on to metformin, or as add-on to metformin + sulfonylurea (SU) in patients with type 2 diabetes mellitus (T2DM). Identical endpoints, study duration, linagliptin dosing, and a large cohort size (N=2,258) facilitated subgroup analyses using the pooled dataset. Given the need for evaluation of the safety and efficacy of new antidiabetic agents on a background of other medications and patient comorbidities, we analysed pooled patient data to evaluate the effect of key patient characteristics on the safety and efficacy of linagliptin. Some research studies have shown a reduced treatment response in patients with longer diabetes duration and increased insulin resistance (IR), thus we determined the response to linagliptin treatment in patients with different diabetes durations and different stages of IR.

Materials and methods: The primary efficacy outcome in all three pooled studies was mean change from baseline in HbA_{1c} at 24 weeks. The incidence of any adverse events (AE) was recorded. Patients were categorised according to the years of diabetes duration: ≤ 1 , >1 -5, and >5 years. Furthermore, patients were categorised according to IR (referred to as HOMA-IR categories): ≤ 4 , >4 - ≤ 5.5 , >5.5 - ≤ 8.5 , >8.5 mU/L*mmol/L.

Results: The mean (\pm SD) patient age and baseline BMI were 57 ± 10 years and 29.0 ± 4.9 kg/m², respectively. Patients were predominantly white (58%) and Asian (42%), with an equal gender distribution. Mean disease duration was up to 1 year in 13% of patients, >1 -5 years in 30% of patients, and >5 years in 57% of patients. Sixty percent of patients were in the HOMA-IR category of ≤ 4.0 mU/L*mmol/L, 15% in the category of >4.0 - ≤ 5.5 mU/L*mmol/L, 13% in the category of >5.5 - ≤ 8.5 mU/L*mmol/L, and 12% in the category of >8.5 mU/L*mmol/L. Forty percent of patients were overweight (mean BMI 27.5 ± 1.4 kg/m²), and 38% were obese (mean BMI 34.1 ± 3.0 kg/m²). Mean baseline HbA_{1c} (\pm SD) and HOMA-IR were $8.1 \pm 0.8\%$ and 4.7 ± 5.3 mU/L*mmol/L, respectively. Significant reductions in HbA_{1c} levels after 24 weeks in the 3 groups of diabetes duration and 4 groups of baseline IR are shown in the figure. The overall hypoglycaemic event rate with linagliptin as monotherapy and add-on to metformin therapy was very low ($\leq 1.0\%$). A higher rate of hypoglycaemic events with linagliptin only occurred in the study that used a background therapy with metformin and SU; this was expected due to the combination with SU.

Conclusion: Treatment with linagliptin provided clinically meaningful HbA_{1c} reductions in patients with T2DM independent of the diabetes duration and the degree of IR, with a safety profile comparable to placebo. The reductions in HbA_{1c} were consistent with results from the primary phase 3 trials.

HbA_{1c} (%) change from baseline at week 24 with linagliptin (difference from placebo)

Achieving the composite end point of HbA_{1c} <7%, no hypos, and no weight gain: comparison between vildagliptin and glimepiride after 2 years of treatment

G. Bader¹, E. Ferrannini², A. Bo³, V. Fonseca⁴, B. Zinman⁵, D. Matthews⁶;

¹Novartis Pharma AG, Basel, Switzerland, ²Department of Internal Medicine and CNR Institute of Clinical Physiology, Pisa, Italy, ³Department of Clinical Sciences, Lund, Sweden, ⁴Department of Endocrinology, Tulane University Health Sciences Center, New Orleans, USA, ⁵Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, Canada, ⁶Oxford Centre for Diabetes, Churchill Hospital and NIHR, UK.

Background and aims: It has previously been shown that, as add-on to metformin vildagliptin has similar efficacy on HbA_{1c} as glimepiride after 2 years of treatment but is associated with markedly reduced hypoglycemia risk and no weight gain. We performed a post-hoc analysis, where we investigated whether there were differences in a clinically relevant composite end point of HbA_{1c} <7%, no hypos (symptoms and plasma glucose <3.1 mmol/L), and no significant weight gain ($<3\%$) in relationship to duration of diabetes and/or the age of the patients.

Materials and methods: In this study, 3118 patients were randomized (vildagliptin, n = 1562; glimepiride, n = 1556): the overall baseline HbA_{1c} was 7.3%. After two years, a similar proportion of patients reached HbA_{1c} <7% (36.9 and 38.3%, respectively with vildagliptin and glimepiride), but with vildagliptin more patients reached this target without hypoglycemia (36.0% vs. 28.8%; p = 0.004).

Results: The data from subjects with baseline HbA_{1c} >7% were analyzed (vildagliptin, HbA_{1c} = 7.6±0.52, n = 1036; glimepiride, HbA_{1c} = 7.6±0.55, n = 980) and are shown in table.

Conclusion: In patients with type 2 diabetes mellitus and baseline HbA_{1c} in the 7 - 8.5 % range, vildagliptin shows a better clinical benefit - as defined by the composite end point of HbA_{1c} <7%, no hypos, and no weight gain, than glimepiride after 2 years of treatment regardless of duration of diabetes or age.

Success rate (SR) (HbA _{1c} < 7% , no hypos, no weight gain)				
	Vildagliptin	Glimepiride	Relative SR	CI 95%

The minimal blood glucose variability is observed in type 2 diabetic patients on metformin plus DPP-IV inhibitors

I.I. Smirnov, L.V. Zhuravlyova, I.A. Ilchenko;

Internal Medicine #3, Kharkov National Medical University, Ukraine.

Background and aims: HbA_{1c} reflects average blood glucose (BG) during last three months before testing. No doubts about an association between HbA_{1c} value and risk of diabetic complications. There are some reasons to suspect but not enough evidence to confirm the influence of blood glucose variability (BGV) as on this risk as on safety of glucose lowering treatment. We aimed to define is there if at all a difference in BGV in type 2 diabetic patients (T2DP) with the similar HbA_{1c} level on different treatment strategies. **Materials and methods:** We studied 94 (45F/49M) T2DP with similar HbA_{1c} in first three to seven month after initiation of different additional treatment added to Metformin in doses not less than 2g/24 since Metformin only became not enough to reach the target HbA_{1c} range. The age was 54.0±5.5y (M±SD), the diabetes duration was 5.3±1.1y, and HbA_{1c} was 7.2±0.4%. 34 T2DP (Group 1) were on sulfonylureas (Gliclazide or Glimepiride), 27 (Group 2) - on DPP-IV inhibitors (Sitagliptine or Saxagliptine), and 33 (Group 3) - on basal insulin (NPH). Groups were matched for gender, age, BMI and diabetes duration. No significant difference between groups in HbA_{1c} on the beginning of an additional treatment was seen. BGV was assessed with continuous glucose monitoring (CGM) system. CGM system high limit of BG was fixed on 9,0mmol/l, low limit - on 4,0mmol/l.

Results: An average monitoring time was near to 72 hours and numbers of sensor values were not differed between groups. In the course of CGM an average BG was 8.5mmol/l, 8.5mmol/l and 8.4mmol/l; min-max BG deviations: 2.7-11.9mmol/l, 3.4-11.4mmol/l and 2.2-14.2mmol/l in Groups 1, 2 and 3 respectively. The table shows CGM results (values are presented as Mean±SD). Table 1.

Index	Groups			P		
	1	2	3	1/2	1/3	2/3
HbA _{1c} (%)	7.22±0.35	7.23±0.43	7.19±0.22	>0.5	>0.5	>0.5
Number of sensor values	873.49±14.61	869.92±18.25	871.41±19.18	>0.5	>0.5	>0.5
Duration above high limit (%)	12.32±4.18	8.50±3.36	13.94±5.80	<0.05	>0.05	<0.05
Duration below low limit (%)	22.52±7.32	8.95±5.34	26.73±8.08	<0.02	<0.05	<0.01
Duration within limits (%)	65.16±5.86	82.55±5.19	59.33±7.92	<0.01	<0.05	<0.001

Conclusion: BGV in different T2DP with equal HbA_{1c} could be significant. The minimal BG excursions were found on DPP-IV inhibitors and the most meaningful were on NPH added to Metformin. How much BGV is clinically important remains unclear and needs further study.

835

The interaction of colessevelam with sitagliptin suggests differential effects on fasting and postprandial glucose metabolism in subjects with type 2 diabetes

G. Smushkin¹, M. Sathananthan¹, C. Dalla Man², P. Giesler¹, J. Laugen¹, G. De Foster¹, C. Cobelli², A. Vella¹;

¹Endocrinology, Mayo Clinic, Rochester, USA, ²Endocrinology, University of Padua, Italy.

Background and aims: Lipid lowering therapy with a bile-acid sequestrant such as colessevelam in people with type 2 diabetes has been associated with a small but significant decrease in HbA_{1c}. However the mechanism of action is unclear, despite suggestions that this is mediated by the incretin pathway. Dipeptidyl peptidase-4 (DPP-4) inhibitors such as sitagliptin raise concentrations of active Glucagon-Like Peptide-1 (GLP-1). As part of a study examining the mechanism of action of colessevelam on glucose metabolism, we examined the interaction of these two compounds and its effects on fasting and postprandial glucose turnover in people with type 2 diabetes.

Materials and methods: We studied 40 subjects with type 2 diabetes treated with metformin using a double blind, placebo-controlled parallel group de-

sign. Upon enrollment, subjects had a standardized, labeled mixed meal labeled with [$1\text{-}^{13}\text{C}$]-glucose. The previously-described triple-tracer technique enabled simultaneous measurement of the systemic rate of meal appearance (Meal Ra), endogenous glucose production (EGP) and glucose disappearance (Rd). Subjects were then randomized to daily treatment with 3.75g of colesevelam or placebo and after a 12-week treatment period, the mixed meal test was repeated. All subjects then participated in an 8-week extension study where they were treated with a combination of colesevelam and sitagliptin, after which the mixed meal test was repeated again. Insulin action and β -cell responsivity (ϕ_{Total}) were calculated using the oral minimal model.

Results: Colesevelam and sitagliptin had an additive effect on fasting and postprandial glucose concentrations. Unlike sitagliptin, colesevelam lowered fasting EGP while not affecting insulin secretion or action g in response to the meal challenge. Sitagliptin did not alter insulin action but stimulated insulin secretion.

Conclusion: The net effects of colesevelam alone on glucose metabolism (decreased EGP, unchanged glucagon concentrations and Disposition Indices) suggest that its effect is not mediated via the incretin system. Nevertheless, it interacts with DPP-4 inhibition to further lower glucose concentrations due to the effect of the latter compounds on insulin secretion (ϕ_{Total}). Intriguingly, colesevelam weakly increases total GLP-1 concentrations perhaps via effects on gastrointestinal motility.

	Fasting glucose (mmol/L)	Integrated Glucose (mol per h)	EGP ($\mu\text{mol/kg/min}$)	ϕ_{Total} (10^{-2}min^{-1})	Peak Total GLP-1 (pmol/L)

Effects of 10-month sitagliptin therapy on HbA_{1c}, triglyceride and remnant cholesterol levels in type 2 diabetic patients

M. Eto, M. Saito;

Clinical Medicine, Ohu University, Fukushima, Japan.

Background and aims: In 2009, sitagliptin became available in Japan. Sitagliptin is an orally active, potent and selective dipeptidyl peptidase-4 (DPP-4) inhibitor for the treatment of type 2 diabetic patients. Sitagliptin acts through increasing incretin (GLP-1 and GIP) hormone concentration, and reduces plasma glucose and HbA_{1c} levels. In addition, DPP-4 inhibitor was reported to reduce plasma triglyceride (TG) level. Remnant lipoproteins which underlie hypertriglyceridemia are known to be atherogenic as well as LDL. However, there is little information about the effect of long-term sitagliptin therapy on HbA_{1c}, TG and remnant cholesterol levels in Japan. The effects of 10-month add-on therapy with sitagliptin on HbA_{1c}, TG and remnant cholesterol levels were examined in Japanese type 2 diabetic patients. In addition, obesity and/or disease duration may impact patient therapeutic response to medication. Thus, this study also evaluated the effect of obesity and/or diabetes duration on glycemic response to sitagliptin therapy in patients whose type 2 diabetes was not optically controlled with glimepiride or pioglitazone.

Materials and methods: Fifty five patients with type 2 diabetes and baseline HbA_{1c} (JDS) $\geq 6.2\%$ to $\leq 7.5\%$ were studied. Mean age was 63 years. All patients were treated with glimepiride (mean dose 1.5 ± 0.1 mg/day) at least for 3 months before the study entry. Sitagliptin 50mg/day was added on after the dose of glimepiride (mean dose 0.6 ± 0.1 mg/day) was reduced to approximately half. Patients were treated with sitagliptin add-on glimepiride over 10 months. HbA_{1c} and plasma lipid levels were compared before and 10 months after add-on therapy with sitagliptin. HbA_{1c} was measured by high-performance liquid chromatography. Plasma remnant cholesterol was determined as RLP-cholesterol (normal range < 5.2 mg/dl) by the method of Nakajima et al. Obesity was defined as BMI ≥ 25 kg/m² according to the criteria in Japanese.

Results: Overall, 10-month add-on therapy with sitagliptin significantly reduced HbA_{1c} level ($6.8 \pm 0.1\% \rightarrow 6.1 \pm 0.1\%$, $p < 0.001$). Reduction in HbA_{1c} from baseline at 10 months was significantly ($p < 0.01$) greater in patients with obesity and diabetes duration < 10 years. Overall, 10-month add-on therapy with sitagliptin significantly reduced TG level ($146 \rightarrow 106$ mg/dl, $p < 0.001$) and

remnant cholesterol level ($6.1 \rightarrow 4.0$ mg/dl, $p < 0.001$). There was no significant change in LDL-cholesterol and HDL-cholesterol levels before and after add-on therapy with sitagliptin. Body weight was not significantly changed, and no adverse reactions such as hypoglycemia were observed over the study period.

Conclusion: It is concluded that 10-month add-on therapy with sitagliptin is effective to reduce plasma TG and remnant cholesterol levels as well as HbA_{1c} in Japanese type 2 diabetic patients with HbA_{1c} $\leq 7.5\%$. In addition, sitagliptin therapy is more effective to reduce HbA_{1c} level in patients with obesity and diabetes duration < 10 years. This is the first report that DPP-4 inhibitor reduces plasma remnant cholesterol.

837

The DPP-4 inhibitor alogliptin reduces postprandial TG and TG-rich lipoproteins in type 2 diabetes

B. Eliasson¹, D. Goede-Möller², K. Eeg-Olofsson¹, C. Wilson³, J. Cederholm⁴, P. Fleck³, M. Diamant², M.-R. Taskinen⁵, U. Smith¹;

¹Department of Medicine, Lundberg Laboratory for Diabetes Research, Gothenburg, Sweden, ²Department of Internal Medicine, VU University Medical Center, Amsterdam, Netherlands, ³Takeda Global Research & Development Centre (Europe) Ltd, London, UK, ⁴Family Medicine and Clinical Epidemiology, Department of Public Health and Caring Sciences, Uppsala, Sweden, ⁵Biomedicum, Helsinki University Hospital, Finland.

Background and aims: Pharmacological inhibition of DPP-4 leading to augmentation of GLP-1 receptor signalling has recently been shown to reduce intestinal lipoprotein secretion in experimental studies, suggesting that DPP-4 inhibitors may offer a novel approach of reducing cardiovascular risk in patients with T2DM. We assessed the effects of alogliptin (ALO) and alogliptin co-administered with pioglitazone (ALO/PIO) compared with placebo (PBO) on postprandial triglyceride (TG)-rich lipoproteins in a randomized clinical trial in subjects with T2DM.

Materials and methods: Double-centre, randomized, double-blind, placebo-controlled, parallel-group study of 16-week duration. Seventy-one patients (age 18–70 years) having failed treatment with diet and exercise, or a stable dose of metformin, sulfonylurea, or glinides for more than three months were recruited. Entry criteria included a baseline HbA_{1c} of 6.5–9.0%, fasting plasma glucose of < 13.3 mmol/L, fasting TG (FTG) of 1.7–5.0 mmol/L, BMI of 23–45 kg/m², an apo E3/3 or E3/4 phenotype, and a stable statin and/or ezetimibe therapy or no lipid-lowering therapy within 3 months prior to screening.

Results: At 16 weeks, ALO reduced FTG by 0.56 mmol/L and ALO/PIO lowered FTG by 0.81 mmol/L compared to PBO ($p = 0.003$ and $p < 0.001$, respectively). Treatment with ALO/PIO significantly increased fasting HDL-C (0.23 mmol/L) from baseline compared to PBO ($p < 0.001$). Both ALO and ALO/PIO produced similar and statistically significant ($P < 0.001$) reductions at week 16 in total postprandial TG response (incremental area under the curve [IAUC]) compared to PBO (TG IAUC reduced by 3.47 vs. 2.87 mmol²/h/L, respectively, NS). Furthermore, both ALO and ALO/PIO led to similar, significant reductions in chylomicron TG and VLDL1-TG IAUCs compared to PBO. Postprandial chylomicron B-48 IAUC showed a significant decrease after treatment with ALO (0.62 mg²/h/L, $p = 0.028$), and a non-significant trend towards a decrease with ALO/PIO (0.33 mg²/h/L, $p = 0.213$). Both ALO and ALO/PIO treatment produced statistically significant reductions in chylomicron cholesterol IAUC at week 16 compared to PBO ($p < 0.001$ and $p = 0.002$, respectively). HbA_{1c} at baseline averaged 6.6%, 6.8% and 6.6% in patients treated with PBO, ALO and ALO/PIO, respectively. In patients randomized to PBO HbA_{1c} increased by 0.4% after 16 weeks to 7.0%, while it decreased by 0.43% to 6.37% and by 0.93% to 5.86% in patients randomized to ALO and ALO/PIO, respectively ($P < 0.001$ for both treatment arms). Treatment with ALO/PIO decreased HbA_{1c} to a significantly greater extent than ALO alone ($P = 0.005$).

Conclusion: Treatment with ALO and ALO/PIO produced reductions in both fasting and postprandial TG and TG-rich lipoproteins as well as HbA_{1c}, contributing to an improved risk factor profile for cardiovascular disease in patients with T2DM and elevated TG levels.

Effects of sitagliptin, acarbose and sulfonylureas on postprandial levels of GLP-1 and GIP in Japanese patients with type 2 diabetes

D. Yabe, K. Watanabe, K. Sugawara, H. Kuwata, Y. Kitamoto, K. Sugizaki, S. Fujiwara, M. Hishizawa, T. Hyo, K. Kuwabara, K. Yokota, M. Iwasaki, N. Kitatani, T. Kurose, Y. Seino;
Division of Diabetes, Clinical Nutrition and Endocrinology, Kansai Electric Power Hospital, Osaka, Japan.

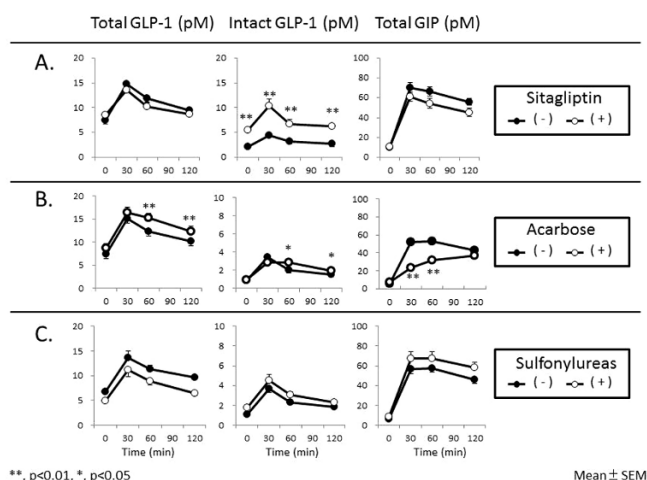

Background and aims: We previously demonstrated that meal-induced GLP-1 secretion is negligible in the Japanese. Thus, therapeutic approaches to enhance GLP-1 secretion or to prevent its degradation could be effective to improve glycemic control in Japanese patients with type 2 diabetes (T2DM). Here, we evaluated effects of sitagliptin, acarbose and sulfonylureas (SU) on postprandial levels of GLP-1 as well as GIP, glucose, insulin and glucagon levels in Japanese T2DM patients.

Materials and methods: Japanese T2DM patients were subjected to meal-tolerance tests using a Japanese standard breakfast (480 kcal; carbohydrate: protein: fat=2.8: 1: 1) with or without drug administration, and incretin levels as well as glucose, insulin, and glucagon levels were determined. To measure incretins, plasma samples were subjected to solid-phase extraction prior to immunoassays. Intact GIP levels were not measured because immunoassays were unavailable.

Results: Two-week administration of once daily 100 mg sitagliptin in 27 patients [Age (year), 62 ± 2 ; BMI (kg/m²), 25.1 ± 1.2 ; HbA_{1c} (NGSP, %), 7.4 ± 0.2] significantly elevated fasting and postprandial levels of intact GLP-1, and significantly increased the area under the curve (AUC) of intact GLP-1 levels after meal ingestions, while total GLP-1 and GIP levels did not change (Figure 1A). One time administration of 100 mg acarbose in 21 patients [Age (year), 61 ± 1 ; BMI (kg/m²), 23.2 ± 0.5 ; HbA_{1c} (NGSP, %), 7.0 ± 0.1] slightly but significantly increased both total and intact GLP-1 levels 60 and 120 min after meal ingestions as well as total GLP-1 AUC (Figure 1B). The acarbose administration significantly decreased total GIP levels 30 and 60 min after meal ingestions as well as total GIP AUC. Postprandial incretin levels in 23 untreated and 18 SU-treated patients [Age (year), untreated 59 ± 2 and SU 67 ± 1 ; BMI (kg/m²), untreated 22.0 ± 0.5 and SU 23.0 ± 0.8 ; HbA_{1c} (NGSP, %), untreated 7.0 ± 0.1 and SU 7.3 ± 0.1] did not differ between two groups (Figure 1C).

Conclusion: In Japanese T2DM patients, sitagliptin, through inhibition of DPP-4-dependent degradation, increased intact GLP-1 levels without affecting secretion of GLP-1 and GIP. Acarbose enhanced GLP-1 secretion and suppressed GIP secretion after meal ingestions. Sulfonylureas had little effects on meal-induced secretion of GLP-1 and GIP.

Better adherence with vildagliptin add-on to metformin than sulphonylurea add-on to metformin among Muslim patients with type 2 diabetes mellitus fasting during Ramadan

W. Hanif¹, W. Malik², M. Hassanein³, A. Kamal², P. Geransar⁴, N. Lister⁴, C. Andrews⁴, A.H. Barnett^{1,2};

¹University of Birmingham, ²Heart of England NHS Foundation Trust, Birmingham, ³Glan Clwyd Hospital, Rhyl, ⁴Novartis Pharmaceuticals UK Ltd., Frimley/Camberley, UK.

Background and aims: During the holy month of Ramadan, Muslim patients with type 2 diabetes mellitus (T2DM) who fast are at increased risk of hypoglycaemia and poor glycaemic control. Factors that can reduce these risks include choice of oral antidiabetes drug (OAD) therapy and patient adherence to treatment. In this study, patients receiving one of two different combination OAD therapies were monitored before, during and after their Ramadan fast. One objective of the study was to assess the number of OAD doses missed during the fasting period, according to therapy.

Materials and methods: This prospective, observational cohort study was conducted in four UK centres. Patients already taking vildagliptin or a sulphonylurea (SU) as add-on therapy to metformin were followed for ≤ 16 weeks (maximum of 6 weeks before and 6 weeks after the fasting period) and asked to record how many doses they missed. Glycated haemoglobin (HbA_{1c}) and hypoglycaemic events (HEs), defined as any symptoms reported by the patient or any blood glucose measurements < 3.9 mmol/l, were also recorded.

Results: Of the 72 patients enrolled (vildagliptin, $n = 30$; SU, $n = 41$; not allocated to treatment, $n = 1$), 59 (81.9%) completed the study (vildagliptin, $n = 23$; SU, $n = 36$) including one patient in the SU arm who completed but failed to provide information on missed doses; all patients in the SU arm were taking gliclazide. In the vildagliptin arm, one patient (4.3%) missed a total of four doses; in the SU arm, ten patients (27.8%) missed a total of 266 doses (mean [SD] number of doses missed per patient: 26.6 [16.5]). The mean (SD) proportion of doses missed during fasting was 0.2% (0.9%) in the vildagliptin arm and 10.4% (21.7%) in the SU arm, with a significant mean between-group difference of -10.2% (95% CI: -19.3% , -1.1%), $p = 0.0292$. No patients reported HEs in the vildagliptin arm and 15 patients (42%) reported 34 HEs (including one grade 2 HE) in the SU arm. Of these 15 patients, more were adherent ($n = 9$, 60%) than were not ($n = 6$, 40%). At baseline, HbA_{1c} was 7.7% in the vildagliptin arm and 7.2% in the SU arm. After fasting, the mean between-group difference (vildagliptin minus SU) was -0.5% (95% CI: -0.9% , -0.1%), $p = 0.0262$.

Conclusion: During Ramadan fasting, almost all patients with T2DM receiving vildagliptin adhered to treatment and none reported HEs. In contrast, nearly half of patients receiving an SU experienced HEs and almost one-third missed doses. Of note, the majority of patients who experienced HEs were adherent. Our findings highlight the importance of choosing an OAD therapy that matches a patient's lifestyle, and suggest that vildagliptin is a suitable treatment option in Muslim patients who fast.

840

Real life experience of usage of vildagliptin versus sulphonylurea therapy in fasting patients with type 2 diabetes during Ramadan: an Indian experience

A.V.V. Shete, Indian Ramadan study group;
Novartis India Limited, Mumbai, India.

Background: Majority of Indian Muslim patients observe the fast during holy month of Ramadan. There is limited data available for Vildagliptin, a selective and orally-effective inhibitor of DPP-IV, which increases active (intact) GLP-1 levels, lowers meal-stimulated glucagon levels, improves glucose tolerance and improves beta cell function; in type 2 diabetes (T2DM) patients. The purpose of this trial was to assess efficacy and safety of Vildagliptin in real day-to-day clinical practice in Indian T2DM patients fasting during Ramadan.

Objective: To compare hypoglycemic events, changes in body weight and change in HbA_{1c}, Fasting blood sugar (FBS) & Postprandial blood sugar (PPBS) levels in Indian Muslim T2DM patients, treated with Vildagliptin or Vildagliptin+metformin combination Vs. sulphonylurea or sulphonylurea+metformin combination, during Ramadan fast.

Materials and methods: A total of 97 patients with mean age of 50.95 years were recruited in this open label, observational, prospective, comparative

study, across 10 centers in India. Patients were randomly selected to receive Vildagliptin or Vildagliptin+metformin (N=55) or sulphonylurea or sulphonylurea+metformin combination (N=42), and observed for the fasting period of 4 weeks (29 days).

Results: The reduction in HbA1c levels pre & post Ramadan (time frame of 4 weeks) was significant at -0.43% (8.75% vs. 8.32%; $p=0.009$; 95%CI) in Vildagliptin group; in contrast there was slight increase in levels of HbA1c by 0.01% (8.64% vs. 8.65%; $p=0.958$; 95%CI) in sulphonylurea group. Also 9(16.37%) more patients reached target HbA1c goal <7% as compared to only 2(4.76%) patients in sulphonylurea group ($p=.055$). During Ramadan, 2(4.76%) hypoglycemic events (1 with glipizide 5mg BID and other with glibenclamide 5mg BID) were reported in the sulphonylurea group (baseline HbA1c=8.64%) compared to none in vildagliptin group (baseline HbA1c=8.75%) ($p=0.104$). The mean FBS & PPBS levels decreased significantly in both the group. Vildagliptin was also associated with a mean weight reduction of -1.02kg (69.13kg vs. 67.93kg; $p=0.000$; 95%CI) pre & post Ramadan, whereas sulphonylurea group had negligible mean weight reduction during fasting period. The between the group difference for mean weight reduction was again statistically significant (-1.02Kg Vs. -0.03Kg; $p=0.011$; 95%CI). The between the group difference for reduction in mean FBS & PPBS levels were not statistically significant.

Conclusion: Like other T2DM patients, improved glycemic control without hypoglycemia is essential in fasting diabetic patients. Unlike sulphonylurea therapy, vildagliptin based therapy offers improved glycemic control with significant HbA1c reduction and better safety with weight reduction and no hypoglycemia event in fasting T2DM Indian patients.

PS 070 SGLT inhibitors: new agents and clinical considerations

841

Characterisation of urinary tract infections in the setting of pharmacologically induced glucosuria

S. Parikh¹, K. Johnsson², A. Ptaszynska³, B. Schmitz³, J. Sugg¹, J.F. List³,
¹AstraZeneca, Wilmington, USA, ²AstraZeneca, Mölndal, Sweden, ³Bristol-Myers Squibb, Princeton, USA.

Background and aims: Type 2 diabetes mellitus (T2DM) predisposes patients to urinary tract infection (UTI). While glucose added to urine has been reported to increase *E. coli* growth in vitro, epidemiological data have not consistently shown an association between increased urinary excretion and UTI. Pooled data from controlled clinical trials with dapagliflozin, an SGLT2 inhibitor that improves glycaemia in patients with T2DM via a dose-dependent increase in renal glucose excretion, offer an opportunity to test this hypothesis.

Materials and methods: The data described here were pooled from 12 randomized, placebo-controlled studies ranging from 12 to 24 weeks in treatment duration. Patients were actively questioned at each trial visit to identify possible urinary tract infections, and the results were evaluated using two analysis methods. In a broad analysis for safety signal detection, the presence of signs and symptoms suggestive of urinary tract infection (e.g., dysuria) as well as clinical diagnoses of urinary tract infection were assessed based on a citation of a set of 63 prespecified MedDRA-preferred terms (PTs). For more specific safety signal quantification the analysis was limited to 49 PTs describing clinically diagnosed infections.

Results: The incidence of signs, symptoms, and events suggestive of UTI with dapagliflozin 2.5 mg was similar to placebo and was higher with dapagliflozin 5 and 10 mg, suggesting a relevant safety signal (Table). Diagnoses of infection were also higher for dapagliflozin 5 and 10 mg than placebo, allowing more specific quantification of this safety signal. Actual events collected during interviews mapped to a limited subset of the PTs. Most signs, symptoms, and events suggestive of UTIs did not recur in the 12-24 weeks, and patients with a history of recurrent UTI were more likely to have an event during the study than those without a prior history. Urine cultures were obtained in ~1/2 of the suggestive events and ~2/3 of these cultures were positive. The majority of events were mild to moderate, and few patients discontinued or interrupted treatment as a consequence. UTIs in all of the dapagliflozin groups were qualitatively similar to those in the placebo group and were also similar to the general T2DM population with respect to pathogens, complications and response to antibiotics. Events of pyelonephritis were infrequent in all groups (Table).

Conclusion: These results suggest that increased renal glucose excretion with the SGLT2 inhibitor dapagliflozin (at doses ≥ 5 mg/day) is accompanied by an elevated incidence of signs, symptoms, and events suggestive of UTI. The actual rates are dependent on the specificity of the PTs analyzed.

Table

		Placebo	Dapagliflozin 2.5 mg/d	Dapagliflozin 5 mg/d	Dapagliflozin 10 mg/d

Dapagliflozin selectively inhibits human SGLT2 versus human SGLT1, SMIT, SGLT4, SGLT6, GLUT1, GLUT2 and GLUT4

S.M. Poucher¹, A. Bellamine², A. Uveges², C. Thompson², H. Xiao², L.M. Abell², G. Mintier², J. DeSchoolmeester¹, J. Ehnebo³, W. Vernon¹, T. Clementz³, J.M. Whaley²;

¹CVGI Discovery, AstraZeneca Pharmaceuticals, Macclesfield, UK, ²Research and Development, Bristol-Myers Squibb, Princeton, USA, ³AstraZeneca, Mölndal, Sweden.

Background and aims: Dapagliflozin, an SGLT2 inhibitor that reduces renal glucose reabsorption and may potentially provide an insulin-independent therapy for the treatment of Type 2 diabetes, is 3,000-fold selective for human SGLT2 vs. human SGLT1 based on K_i values. Here we report selectivity versus other glucose transporters.

Materials and methods: SMIT (SLC5A3), SGLT4 (SLC5A9) and SGLT6 (SLC5A11) were stably expressed in CHO cells. SGLT 1, 2 and 4 activity was assessed with sodium-dependent ¹⁴C- α -methyl glucopyranoside (AMG) uptake. SMIT and SGLT6 activity was assessed with sodium-dependent ¹⁴C-myoinositol uptake. The uptake was carried out at 37°C for 2 hr in presence of phlorizin at 50–500 μ M or dapagliflozin at 0.5–500 μ M. Activity of dapagliflozin at human GLUT1, 2 and 4 transporters was assessed in human erythrocytes, Hep G2 cells and human differentiated adipocytes, respectively. GLUT1 activity was measured using D-[6-³H] glucose transport. GLUT2 activity was assessed using 2-deoxy-D-[1-³H] glucose transport. GLUT4 activity was measured using insulin stimulated 2-deoxy-[U-¹⁴C]-glucose. Dapagliflozin was pre-incubated for an hour prior to the administration of the relevant glucose analogue over the concentration range 20–100 μ M to assess GLUT selectivity

Results: The K_i values for the inhibition by dapagliflozin at the SGLT isoforms and the inhibition of GLUT isoforms are described in the table below. We have demonstrated that dapagliflozin is highly selective for human SGLT2 and the inhibition constants for dapagliflozin vs. SGLT1, SMIT, SGLT4 and SGLT6 are 3000, 70,000, 16,500 and 4,050-fold higher than for SGLT2. Phlorizin is 250-fold less potent than dapagliflozin at SGLT2, and is 3-fold, 3,000-fold, 110-fold and 260-fold selective vs. SGLT1, SMIT, SGLT4 and SGLT6, respectively. Dapagliflozin had no effect on the insulin EC_{50} value for glucose uptake in the human adipocytes. Dapagliflozin also had minimal effect at GLUT1 and GLUT2 at 100 μ M. Although dapagliflozin inhibited GLUT4 by 23±4% at 100 μ M, a concentration of 20 μ M had minimal effect on the maximum response (8 ± 2% reduction). Positive response to cytochalasin B and/or phloretin were observed for all systems studied in the GLUT transport studies. This data also shows that the compound has at least 100,000-fold selectivity over GLUT1, 2 and 4.

Conclusion: At concentrations achieved following administration of therapeutic concentrations of dapagliflozin, we do not expect off-target effects attributable to inhibition of SGLT1, SGLT4, SMIT or SGLT6 transporters or GLUT1, 2 or 4 proteins or adverse effects upon insulin stimulated glucose disposal.

Table

SGLT Isoform	SGLT1	SGLT2	SGLT3	SGLT4	SGLT6
System Name	SLC5A1	SLC5A2	SLC5A3	SLC5A9	SLC5A11
Dapagliflozin/ K_i (μ M)	0.61 ± 0.18	2.10 × 10 ⁻⁴ ± 6.10 × 10 ⁻⁵	14 ± 2	3.3 ± 0.7	0.81 ± 0.12

Dapagliflozin, a selective SGLT2 inhibitor, reduces serum levels of uric acid in patients with type 2 diabetes

E. Hardy¹, K. Rohwedder², V. Hrub³, A. Salsali⁴, L. Ying⁴, J. Sugg¹, J.F. List⁴, S. Parikh¹;

¹AstraZeneca, Wilmington, USA, ²AstraZeneca, Wedel, Germany, ³AstraZeneca, Prague, Czech Republic, ⁴Bristol-Myers Squibb, Princeton, USA.

Background and aims: Serum uric acid is an emerging marker for cardiovascular and renal disease risk. Dapagliflozin, a selective inhibitor of the renal sodium-glucose cotransporter 2 (SGLT2), reduces hyperglycaemia in patients with type 2 diabetes independently of insulin action or secretion by increasing urinary glucose excretion, and has been associated with reductions in serum uric acid. The effect of dapagliflozin on changes in uric acid from data collected in five Phase 3 studies is reported; the main findings of these studies have been previously reported.

Materials and methods: Comparative changes from baseline in serum uric acid are reported for a 24-week study of dapagliflozin monotherapy in treatment-naïve patients inadequately controlled with diet and exercise (NCT00528372); a 102-week study of dapagliflozin as add-on to metformin in patients inadequately controlled by metformin alone (NCT00528879); a 52-week study of dapagliflozin versus glipizide (both titrated to goal) as add-on to metformin in patients inadequately controlled by metformin alone (NCT00660907); a 48-week study of dapagliflozin as add-on to glimepiride in patients inadequately controlled by glimepiride alone (NCT00680745); and a 48-week study of dapagliflozin as an add-on to insulin in patients inadequately controlled by insulin ± other oral antidiabetic drugs (NCT00673231). Serum uric acid was recorded as either an exploratory efficacy variable (NCT00528372, NCT00528879) or as a safety variable (NCT00660907, NCT00680745, NCT00673231). Urinary uric acid levels were not examined in these studies.

Results: Mean serum uric acid reductions from baseline with dapagliflozin treatment ranged from 11.3 to 59.5 μ mol/L, and were sustained for up to 102 weeks. Placebo and glipizide treatment were not associated with uric acid reductions.

Changes in Serum Uric Acid in Dapagliflozin Studies

Study ID	Design	Dose of dapagliflozin or comparator (mg/day)	N	Time from baseline (weeks)	Mean baseline serum uric acid (μ mol/L)	Mean change from baseline (μ mol/L)	Confidence/error (95%CI) or [SE]

		5	212		323.6	-12.5	[4.7]
		10	196		324.8	-14.3	[4.9]
		Placebo	197		333.7	4.2	[4.8]

*Exploratory efficacy variable; †Data are adjusted means from ANCOVA (last observation carried forward); ‡Data from safety analysis sets; §mean titrated dose 16.4 mg for glipizide and 9.2 mg for dapagliflozin; N = number of patients randomized and treated; QAM = morning administration; QPM = evening administration.

Conclusion: Dapagliflozin consistently lowered serum uric acid levels across five Phase 3 studies examining a range of different clinical scenarios. Whether this is a direct effect on a uric acid transporter or an indirect effect related to urinary glucose excretion is unknown. Further research is needed to establish the clinical significance of modest uric acid reductions in patients with type 2 diabetes who have normal baseline uric acid levels.

The sodium glucose co-transporter-2 (SGLT2) inhibitor, PF04971729, yielded BP lowering in hypertensive patients with type 2 diabetes mellitus

N.B. Amin, X. Wang, G. Nucci, J.M. Rusnak;
CVMED Research Unit, Pfizer, Groton, USA.

Background and aims: PF04971729 is a highly potent and selective SGLT2 inhibitor in development for treatment of T2DM. This phase 2, randomized, placebo-controlled, double-blind, double-dummy study investigated the efficacy and safety of PF04971729 in patients with hypertension (HTN) and T2DM. At screening, patients were on 1 or 2 oral anti-diabetic agents (excluding thiazolidinediones), plus up to 2 anti-hypertensive agents with those affecting renin-angiotensin-aldosterone-system (RAAS) stopped 3 weeks prior to randomization.

Materials and methods: A total of 194 patients (32% female) were randomized, to once daily oral doses of placebo, 1 of 3 doses of PF04971729, or 12.5 mg hydrochlorothiazide (HCTZ), for 4 weeks. Mean baseline characteristics were HTN duration 6 years, T2DM duration 7 years, HbA1c 8.2%, 24-h average BP 136/81 mmHg (ambulatory blood pressure monitoring - ABPM) and 136/84 mmHg (seated, trough measurements). Efficacy endpoints were 24-h, day-time, and night-time BP, as well as seated, trough BP, markers of RAAS, and fasting plasma glucose (FPG). Assessments of safety and tolerability were also included. For endpoints with 1 post-treatment measure at Week 4, analysis of covariance (ANCOVA) was applied on observed data; for endpoints with more than 1 measurement post-randomization, mixed model repeated measures (MMRM) was utilized on all observed data.

Results: A total of 184 subjects completed the study. The table below summarizes the results. The frequency of adverse events (AEs) was similar across all arms with none of the subjects withdrawn due to AEs. There were no cases of pyelonephritis reported. Urinary tract infections were reported in a total of 5 patients (1 on placebo, 4 on PF04971729); genital fungal infections were reported in 4 patients (all on PF04971729).

Conclusion: In patients with HTN and T2DM, administration of once-daily PF04971729 for 4 weeks resulted in a clinically meaningful decrease in BP along with improvement in glycemic control. The BP lowering efficacy, at least comparable to that of HCTZ, warrants further investigation in combination with ACE-inhibitors or angiotensin receptor blockers.

Long-term treatment of TS-071, a novel, potent and selective SGLT2 inhibitor, improves hyperglycaemia and prevents the loss of beta cell in diabetic mice

T. Teisuke, A. Kozakai, N. Kojima, E. Gunji, K. Kitano, T. Takeda, K. Takano, Y. Yasuda, S. Uchida, K. Takahashi;
Pharmacology, Taisho Pharmaceutical Co. Ltd., Saitama, Japan.

Background and aims: We have discovered a novel SGLT2 inhibitor, TS-071 (TS), which increases urinary glucose excretion and provides insulin-independent reduction of hyperglycemia in vivo. The aim of this study is to assess the in vitro profile of TS and to evaluate the long-term efficacy of this compound on hyperglycemia and β -cell injury in diabetic mice. Sitagliptin (SITA) and pioglitazone (PIO) were used as reference compounds.

Materials and methods: The in vitro potency and property of TS were evaluated using CHO-K1 cells overexpressing human SGLT2. In the in vivo experiments, high fat-fed streptozotocin-treated (HFD/STZ) mice were given orally vehicle (VEH), TS or SITA for 12 weeks. Plasma glucose (PG) and glycated hemoglobin (GHb) were measured, and the pancreas was isolated to analysis of insulin content. Eleven-week-old db/db mice were given orally VEH, TS or PIO for 8 weeks, PG, GHb and plasma triglyceride (TG) were measured. Pancreatic β -cell area was evaluated by histological analysis. To further elucidate the combination effects of TS with metformin (MET), 11-week-old db/db mice were orally given VEH, TS, MET or combined TS and MET (TS+MET) for 10 weeks. GHb and pancreatic β -cell area were assessed at the end of the study.

Results: In CHO-K1 cells overexpressing human SGLT2, TS competitively inhibited Na⁺-dependent ¹⁴C- α -methylglucoside uptake with a Ki value of 1.10 nM. In HFD/STZ mice, both TS and SITA significantly decreased the change in GHb [Δ GHb (%): VEH = 0.33 ± 0.4, TS 1 mg/kg = -0.12 ± 0.3, TS 3 mg/kg = -0.61 ± 0.3, TS 10 mg/kg = -1.09 ± 0.1*, SITA 200 mg/kg = -1.09 ± 0.3*, *p < 0.05 vs. VEH] and increased pancreatic insulin contents (μ g/g pancreas: VEH = 29.3 ± 4.9, TS 1 mg/kg = 38.8 ± 3.8, TS 3 mg/kg = 43.0 ± 4.6, TS 10 mg/kg = 53.5 ± 5.7**, SITA 200 mg/kg = 55.1 ± 10.3*, *p < 0.05, **p < 0.01 vs. VEH). In db/db mice, TS (3 mg/kg) significantly decreased PG, GHb and TG [fasting PG (mg/dL): VEH 796 ± 36 vs. TS 535 ± 22, P < 0.001; GHb (%): VEH 9.5 ± 0.3 vs. TS 6.9 ± 0.2, p < 0.001; fasting plasma TG (mg/dL): VEH 87 ± 14 vs. TS 47 ± 5, p < 0.05]. TS significantly restored the pancreas β -cell mass [insulin-positive area to total islet area (%): VEH 21.5 ± 1.6 vs. TS 31.8 ± 2.3, p < 0.01] and reduced the pancreas α -cell mass [glucagon-positive area to total islet area (%): VEH 12.1 ± 1.2 vs. TS 6.9 ± 0.7, p < 0.01]. PIO (10 mg/kg) also improved glycemic control and restored the pancreas β -cell mass, but had no effect on the pancreas α -cell mass. Combination treatment with TS (3 mg/kg) and MET (300 mg/kg) significantly reduced GHb compared with MET alone [GHb (%): MET 9.9 ± 0.4 vs. TS+MET 8.2 ± 0.4, p < 0.05]. TS+MET also demonstrated significant improvement in the pancreas β -cell mass compared with MET alone [insulin-positive area to total islet area (%): MET 13.1 ± 1.5 vs. TS+MET 23.9 ± 2.5, p < 0.01].

Conclusion: These results indicate that TS, either as monotherapy or in combination with MET, improved glycemic control and preserved β -cell mass in diabetic mice.

846

TS-071, a novel potent and highly selective renal sodium-glucose co-transporter 2 (SGLT2) inhibitor, increases urinary glucose excretion and reduces plasma glucose levels in Japanese patients with type 2 diabetes mellitus

T. Sasaki¹, Y. Seino², A. Fukatsu³, Y. Samukawa⁴, S. Sakai⁴, T. Watanabe⁴;
¹Jikei University School of Medicine, Chiba, ²Kansai Electric Power Hospital, Osaka, ³Kyoto University Hospital, ⁴Taisho Pharmaceutical Co., LTD., Tokyo, Japan.

Background and aims: Renal sodium-glucose co-transporter 2 (SGLT2) inhibition is known as a new approach for the treatment of type 2 diabetes mellitus (T2DM). TS-071 is a novel, orally bioavailable, and highly selective SGLT2 inhibitor. This is the clinical pharmacology study to evaluate pharmacodynamic (urinary glucose excretion (UGE), plasma glucose levels), pharmacokinetic (PK) and safety in Japanese patients with T2DM.

Materials and methods: In single-blind, placebo (PBO) -controlled, parallel group, clinical pharmacology study, subjects (N=40) were randomized to TS-071 0.5, 1, 2.5, 5 mg once daily (QD) or PBO for 7 days administration. Mean baseline characteristics in each group were HbA1c 7.99 - 8.70 %, fasting

plasma glucose (FPG) 150.1–166.5 mg/dL, age 55.9–59.8 years, BMI 23.4–26.8 kg/m² and body weight 66.8–76.0 kg.

Results: UGE up to 24 hours (UGE-24hr) after administration on Day 1 and Day 7 significantly increased in all the TS-071 treatment groups compared to PBO group. UGE-24hr on Day 7 was dose-dependent, and least squares means of difference between each treatment group and PBO group were 49.2, 66.5, 89.4 and 101 g in 0.5 mg, 1 mg, 2.5 mg and 5 mg group respectively. The values of plasma glucose AUC on Day 7 after breakfast and after lunch were significantly lower in all TS-071 groups compared to placebo group, and the values after supper were also significantly lower in 1 mg–5 mg groups excluding 0.5 mg group compared to PBO group. TS-071 showed reductions in plasma glucose levels throughout the day by QD administration. Plasma TS-071 concentrations increased dose-dependently. Dose-proportionality was observed in C_{max} and AUC_{0–24} on Day 7. It was assumed that there would be no effect of repeated administration such as accumulation. Plasma pharmacokinetics in T2DM patients in the 5 mg group was similar to that in healthy subjects. No major or serious safety concern was observed in all TS-071 groups. Nine adverse events occurred in 7 subjects. All the adverse events were mild in severity and recoverable. Out of these adverse events, only an adverse drug reaction of constipation was observed in a subject (0.5 mg group). There were no findings suggesting hypoglycemia and urinary tract infection. It was concluded that there would be no problem with tolerability in this study.

Conclusion: In patients with T2DM, once daily administration of TS-071 demonstrated dose-dependent UGE increase, reductions in plasma glucose levels throughout the day and showed favorable profile of PK and safety.

The effect of renal impairment on the pharmacokinetics and urinary glucose excretion of the SGLT2 inhibitor ipragliflozin (ASP1941) in Japanese type 2 diabetes mellitus patients

T. Kadokura¹, H. Ishikawa¹, I. Nakajo¹, S. Yoshida¹, A. Utsuno¹, R.A. Smulders², K. Morozumi³

¹Development, Astellas Pharma Inc., Tokyo, Japan, ²Astellas Pharma Global Development, Leiderdorp, Netherlands, ³Nagoya Daini Red Cross Hospital, Japan.

Background and aims: Sodium-dependent glucose co-transporter 2 (SGLT2) is primarily responsible for the reabsorption of glucose in the renal proximal tubules. Ipragliflozin (ASP1941) is a novel, potent, and selective SGLT2 inhibitor that induces an increase in urinary glucose excretion (UGE), thereby reducing plasma glucose levels. This study investigated the effect of different degrees of renal impairment (RI) on the pharmacokinetics of and the UGE induced by ipragliflozin, in Japanese type 2 diabetes mellitus (T2DM) patients.

Materials and methods: T2DM patients with normal renal function (NRF; estimated glomerular filtration rate [eGFR] ≥ 90 mL/min/1.73m²), and mild (eGFR 60–89 mL/min/1.73m²) and moderate (eGFR 30–59 mL/min/1.73m²) RI were enrolled. Patients were administered a single oral dose of 50 mg ip-

ragliflozin (n = 8–9 per renal function group). Plasma concentrations of ipragliflozin, UGE, and safety were assessed up to 72 hours after dosing.

Results: In T2DM patients with mild RI, the maximum plasma concentration (C_{max}) of ipragliflozin was increased by 12%, and the area under the plasma concentration-time curve from time of dosing to infinity (AUC_{inf}) was comparable to patients with NRF. In T2DM patients with moderate RI, C_{max} and AUC_{inf} of ipragliflozin were increased by 17% and 21%, respectively, compared with T2DM patients with NRF. Mean daily UGE increased in all groups. Mean changes from baseline in UGE were comparable between patients with mild RI and NRF, and lower in patients with moderate RI versus NRF patients. Mean changes from baseline in plasma glucose levels 24 hours after administration (before breakfast) were –24.9 mg/dL in T2DM patients with NRF, –11.9 mg/dL in patients with mild RI, and –4.1 mg/dL in patients with moderate RI. As for safety, a single dose of 50 mg ipragliflozin was considered safe and well tolerated in T2DM patients with normal, mildly impaired, and moderately impaired renal function.

Conclusion: Ipragliflozin exposure increased in T2DM patients with moderate RI by 21%. The UGE after ipragliflozin dosing was reduced in T2DM patients with moderate RI. Ipragliflozin was well tolerated in the study population.

Clinical Trial Registration Number: NCT01097681

Effects of dapagliflozin on patient reported treatment satisfaction in patients with type 2 diabetes mellitus: results from two double-blind trials

J. Medin¹, S. Grandy², K. Rohwedder³, V. Hrubá⁴, J. Sugg⁵, A.-M. Langkilde⁶; ¹HEOR, AstraZeneca, Mölndal, Sweden, ²HEOR, AstraZeneca, Wilmington, USA, ³AstraZeneca, Wedel, Germany, ⁴AstraZeneca, Prague, Czech Republic, ⁵AstraZeneca, Wilmington, USA, ⁶AstraZeneca, Mölndal, Sweden.

Background and aims: Sodium-glucose co-transporter 2 (SGLT2) inhibitors represent a new treatment modality for type 2 diabetes mellitus (T2DM) which lower blood glucose by increasing urinary glucose excretion. Dapagliflozin (DAPA) is a first in class SGLT2 inhibitor in clinical development and has been shown to improve HbA1c and reduce weight, and is safe and well tolerated. However, its novel glucosuric mechanism of action warranted an evaluation of patient treatment satisfaction.

Materials and methods: Patient-reported treatment satisfaction was measured utilizing the Diabetes Treatment Satisfaction Questionnaires for status (DTSQs max score 36) and change (DTSQc max score 18). Data were collected from two randomized, double-blind, multicenter, parallel group studies (N=1411), Study 4 and Study 5, in the DAPA phase III program. Study 4 was a 2-arm, 52 week study of DAPA up to 10 mg vs glipizide (GLIP) up to 20 mg, both added to metformin (N=814), and Study 5 was a 24 week study + 24 week extension of DAPA 2.5, 5 or 10 mg vs placebo (PBO), both added to glimepiride (N=597).

Results: The overall DTSQs scores at baseline were high in all groups in both studies (>30 in Study 4, and > 27 in Study 5). In Study 4, the DTSQs showed a slight increase in both treatment groups at week 26. The DTSQc score at week 52 in Study 4 showed a higher mean value in the DAPA group (14.3 vs GLIP 13.6). In Study 5 at week 24, the DTSQs showed a slight increase in all groups and the DTSQc ranged from 13.2 to 13.6 in the DAPA groups vs 13.0 for PBO. At week 48, the DTSQs score improved further in all DAPA groups (mean change 3.5, 4.6, 4.4) vs PBO (2.2). In the single item measuring perceived frequency of hyperglycemia there was a noticeable reduction with DAPA compared with PBO at weeks 24 and 48.

Conclusion: The high level of treatment satisfaction maintained by patients in these 2 studies with ≥ 48 weeks of treatment suggests that dapagliflozin with its novel mechanism of action through glucosuria provides a well tolerated therapeutic option for patients with T2DM.

Combination treatment with ipragliflozin (ASP1941) and metformin in type 2 diabetes patients: a safety, pharmacokinetic and pharmacodynamic interaction study

S.A. Veltkamp, J. van Dijk, W.J.J. Krauwinkel, R.A. Smulders; Astellas, Leiderdorp, Netherlands.

Background and aims: Ipragliflozin (ASP1941), a novel selective inhibitor of sodium-dependent glucose co-transporter 2 (SGLT2), is in clinical development for the treatment of type 2 diabetes mellitus (T2DM). Inhibition of SGLT2 by ipragliflozin reduces glucose reabsorption from the proximal tubules of the kidney, thereby enhancing urinary glucose excretion (UGE). Metformin is commonly used as first line treatment in T2DM; however, many T2DM patients do not achieve or retain glycemic targets with metformin alone, partly due to side-effects, and therefore require additional pharmacotherapy. Here we report the safety of combination treatment with ipragliflozin and metformin, the effect of ipragliflozin on the pharmacokinetics (PK) of metformin, and the effect of concomitant use of ipragliflozin and metformin on the pharmacodynamics (PD) in T2DM patients.

Materials and methods: This was a double-blind, randomized, placebo-controlled, parallel design study. T2DM patients who were stable on metformin therapy (850 mg twice-daily [bid], 1000 mg bid, or 1500 mg bid) received either ipragliflozin 300 mg or placebo once daily (qd) for 14 days. Safety outcomes, comprising adverse events (AEs), laboratory measurements and vital signs, were assessed during the study. PK of metformin was determined in plasma using a validated liquid chromatography-tandem mass spectrometry method. PD was assessed by measurement of UGE.

Results: In total, 36 T2DM patients were included in the study ($n = 18$ per group), and received either ipragliflozin (mean age \pm standard deviation [SD] = 59 ± 8.5 years) or placebo (mean age \pm SD = 56 ± 10.9 years). The most frequent treatment emergent AEs were gastrointestinal (GI) disorders (a known and common AE of metformin), and these were reported both in ipragliflozin and placebo-treated patients (3 out of 18 patients in each group). GI disorders in the ipragliflozin group comprised diarrhea (mild, $n = 1$), dry mouth (mild, $n = 1$), nausea (moderate, $n = 1$), and vomiting (moderate, $n = 1$). Diarrhea (mild, $n = 1$) and flatulence (mild, $n = 2$) were reported in the placebo group. No symptomatic or asymptomatic (finger prick < 3 mmol/L) hypoglycemic events were reported. The change from baseline in plasma exposure (area under the concentration-time curve [AUC]) of metformin on Day 14 was slightly higher in the ipragliflozin group (AUC_{0-10h} ratio Day 14/baseline = 1.18; 90% confidence interval [CI] 1.08–1.28) than in the placebo group (AUC_{0-10h} ratio Day 14/baseline = 0.93; 90% CI 0.86–1.00). As expected, UGE was higher in patients on concomitant treatment of metformin and ipragliflozin (mean \pm SD Ae_{0-24h} glucose Day 14 was 74.9 ± 31.5 g) compared with patients on metformin and placebo (mean \pm SD Ae_{0-24h} glucose Day 14 was 3.56 ± 4.0 g). **Conclusion:** Multiple dosing of ipragliflozin 300 mg qd for 2 weeks was safe and well tolerated in T2DM patients on stable metformin therapy, with no signs of hypoglycemia observed. Combination treatment with ipragliflozin and metformin did not result in clinically relevant changes in AUC of metformin. UGE clearly increased in T2DM patients on concomitant treatment of metformin and ipragliflozin compared with patients on metformin and placebo.

The sodium glucose co-transporter-2 (SGLT2) inhibitor, PF04971729, provides multi-faceted improvements in diabetic patients inadequately controlled on metformin

G. Nucci, N.B. Amin, X. Wang, D.S. Lee, J.M. Rusnak; CVMED Research Unit, Pfizer, Inc, Groton, USA.

Background and aims: PF04971729 is a new, highly potent and selective SGLT2 inhibitor in development for treatment of type 2 diabetes mellitus (T2DM). This phase 2, randomized, placebo-controlled, double-blind, double-dummy study investigated the efficacy and safety of PF04971729 in patients with T2DM standardized on background of metformin ahead of randomization.

Materials and methods: A total of 328 patients (35% female) with T2DM and baseline characteristics (mean) of T2DM duration 6.3 years, HbA1c 8.1%,

body weight (BW) 83.8 kg, and blood pressure of 126/79 mmHg were randomized, to once daily doses of placebo, PF04971729 1 mg, 5 mg, 10 mg and 25 mg, or sitagliptin 100 mg for 12 weeks. Efficacy endpoints were HbA1c, BW, fasting plasma glucose (FPG), systolic and diastolic blood pressure (sBP and dBP) and fasting plasma insulin (FPI). Assessments of safety and tolerability were also included.

Results: Significant changes from baseline were observed in all parameters with PF04971729 as shown in the table below (analysis at Week 12, mean \pm se). The frequency of adverse events (AEs) by treatment group was numerically comparable across all treatment arms studies. The number of subjects withdrawn due to AEs was 9/328 (2.7%) and evenly distributed across all arms. Overall, there was no dose-related increase in frequency of AEs with increasing PF04971729 dose. There were no cases of pyelonephritis reported. The frequency of symptomatic urinary tract infections was 2.3% (PF04971729 arms combined) and 3.7% with placebo. The frequency of genital fungal infections was 3.6% pooled across PF04971729 doses versus 1.8% with placebo.

Conclusion: In patients with T2DM sub-optimally controlled on metformin, administration of once-daily PF04971729 appeared safe and well tolerated and resulted in meaningful, multi-faceted improvements in glycemic control, body weight, and blood pressure.

Dapagliflozin added-on to pioglitazone is effective in improving glycaemic control and attenuates weight gain without increasing hypoglycaemia in patients with type 2 diabetes

M. Vico¹, L. Wei², A. Salsali², J.F. List², J. Rosenstock³;

¹Instituto de Investigaciones Clínicas Zarate, Buenos Aires, Argentina,

²Bristol-Myers Squibb, Princeton, USA, ³Dallas Diabetes and Endocrine Center, Dallas, USA.

Background and aims: Dapagliflozin (DAPA), an SGLT2 inhibitor, acts independently of insulin secretion or action. In clinical trials, DAPA has been shown to reduce hyperglycaemia and improve glycaemic control in patients with type 2 diabetes (T2DM) alone or added-on to metformin, sulfonylurea or insulin. This report examines DAPA added-on to the thiazolidinedione (TZD), pioglitazone (PIO).

Materials and methods: The primary objective was HbA_{1c} change from baseline with DAPA+PIO versus placebo (PBO)+PIO at week 24 in patients with T2DM who were inadequately controlled on PIO alone having HbA_{1c} ≥ 7.0 – $\leq 10.5\%$. Following run-in periods of 2 weeks for those on previous PIO (48%) or of 12 weeks for those starting PIO (52%), patients on PIO ≥ 30 mg were randomised to DAPA 5 or 10 mg or PBO QD plus open-label PIO.

Results: Mean baseline demographics included: age 53.5 yr, duration T2DM of 5.5 yr, HbA_{1c} 8.4%, FPG 9.16 mmol/L, weight 86 kg, and 78% of patients had BMI ≥ 27 kg/m². Significant mean reductions occurred in HbA_{1c}, FPG, and 120-min PPG at week 24 and maintained through week 48 in both DAPA groups (Table). Body weight gain occurred in the placebo group while no meaningful change from baseline was noted in the DAPA 10 mg group. The adjusted mean changes from baseline for body weight were statistically significant for the DAPA 10 mg group at week 24 and maintained throughout week 48 (Table). Discontinuations were low and similar in DAPA and PBO groups. The proportion of patients reporting at least one AE was similar for the DAPA and placebo groups through week 48. Through 48 weeks, one patient on placebo, and three patients on DAPA 5 mg experienced hypoglycaemia episodes while no hypoglycaemia occurred in the DAPA 10 mg group. No episodes of major hypoglycaemia events were reported. Signs and symptoms suggestive

of genital infection were reported in 8.6–9.2% on DAPA versus 2.9% on PBO through 48 weeks. No clear drug effect was observed on the frequency of signs and symptoms suggestive of UTIs; the proportion of patients with signs and symptoms suggestive of UTI was 7.9% for placebo, 8.5% for DAPA 5 mg and 5.0% for DAPA 10 mg through 48 weeks.

Conclusion: In patients with T2DM who were inadequately controlled on TZDs, the addition of DAPA improved HbA_{1c}, FPG, and 120-min PPG. DAPA was well tolerated, and mitigated the weight gain of PIO without increasing hypoglycaemia risk.

Long-term efficacy and safety of add-on dapagliflozin vs add-on glipizide in patients with type 2 diabetes mellitus inadequately controlled with metformin: 2-year results

S. Del Prato¹, M.A. Nauck², K. Rohwedder³, A. Theuerkauf⁴, A.M. Langkilde⁵, S. Parikh⁶;

¹Endocrinology and Metabolism, University of Pisa, Italy, ²Diabeteszentrum Bad Lauterberg, Germany, ³Endocrinology and Metabolism, AstraZeneca, Wedel, Germany, ⁴ClinResearch, Koeln, Germany, ⁵AstraZeneca, Mölndal, Sweden, ⁶AstraZeneca, Wilmington, USA.

Background and aims: Dapagliflozin (DAPA), a selective SGLT2 inhibitor, reduces hyperglycemia by increasing urinary glucose excretion in a manner independent of insulin secretion or action. In subjects with T2DM inadequately controlled on MET, 1-year results of a randomized, double-blind trial of DAPA (up to 10 mg/d; n=406) or glipizide (GLIP, up to 20 mg/d; n=408) added to open-label MET (median 2000 mg/d) have been reported (D1690C00004). The primary endpoint was change in HbA_{1c} at year 1 with 0.52% reduction in both arms. While DAPA was non-inferior to GLIP in reduction of HbA_{1c} at year 1, DAPA produced weight loss, and reduced risk of hypoglycemia compared with GLIP. We now report efficacy and safety over 2 years of treatment of DAPA+MET compared with GLIP+MET.

Materials and methods: In the year of double-blind extension, subjects continued to receive DAPA (n=315) or GLIP (n=309) added to MET. During the first 18 weeks of the first year of the study, medication was up-titrated based on FPG; a one-time up-titration was allowed in the second year of treatment. Glycemic efficacy and weight change were analyzed over 2 years by longitudinal repeated-measures analysis and reported as adjusted mean changes with 95% CI. Proportion of patients with ≥ 1 episode of hypoglycemia was calculated.

Results: Mean overall baseline HbA_{1c} was 7.72%. Entering year 2, 90.5% of DAPA and 73.1% of GLIP subjects were taking maximum doses. At the end of year 2, change in HbA_{1c} with DAPA was -0.32% (-0.42, -0.21) vs -0.14% (-0.25, -0.03) with GLIP. Body weight reduction seen at year 1 with DAPA was sustained through year 2: -3.70 kg (-4.16, -3.24) vs +1.36 (0.88, 1.84) for GLIP. Proportion of subjects with ≥ 5% weight loss was 23.8% with DAPA and 2.8% with GLIP. Dapa had low risk of hypoglycemia over 2 years: 4.2% vs GLIP 45.8% of subjects experienced ≥1 episode of hypoglycemia. Systolic blood pressure was reduced with DAPA, -2.7 mm Hg (-4.2, -1.2) vs +1.2 mm Hg (-0.4, 2.8) with GLIP. The overall rate of AEs remained similar between arms over 2 years. On active questioning, the proportion of subjects reporting signs, symptoms, and events suggestive of UTI was 13.5 % for DAPA and

9.1% for GLIP and the proportion of subjects reporting signs, symptoms, and events suggestive of genital infections was 14.8% for DAPA (8.0% in men, 23.3% in women) and 2.9% (0.4% in men, 5.9% in women) for GLIP over 2 years. The majority of events occurred in year 1, were mild to moderate in intensity, and responded to standard care. One discontinuation in each arm due to UTI and 3 discontinuations in the DAPA arm due to genital infections occurred during year 1; no discontinuations due to UTI or genital infections were reported during year 2. There was no relevant change in renal function measured by eGFR over 2 years.

Conclusion: DAPA treatment in patients with T2DM inadequately controlled on MET showed sustained glycemic efficacy and weight loss with low risk of hypoglycemia over a 2-year period compared with GLIP. Higher frequencies of events suggestive of genital infections and UTI were reported, mainly in the first year. These responded to standard treatment and rarely led to discontinuation.

Dapagliflozin, a selective SGLT2 inhibitor, has a low propensity to cause hypoglycaemia in patients with type 2 diabetes

K. Rohwedder¹, V. Hrub², A. Salsali³, L. Ying³, J. Sugg⁴, J.F. List³, S. Parikh⁴;

¹AstraZeneca, Wedel, Germany, ²AstraZeneca, Prague, Czech Republic,

³Bristol-Myers Squibb, Princeton, USA, ⁴AstraZeneca, Wilmington, USA.

Background and aims: Hypoglycaemia is associated with recurrent morbidity in patients with type 2 diabetes mellitus (T2DM), and is often a barrier to achieving glycaemic targets. Dapagliflozin (dapa), a selective inhibitor of renal sodium-glucose cotransporter 2 (SGLT2), reduces hyperglycaemia in patients with T2DM by increasing urinary glucose excretion. This effect depends on baseline glycaemic control and renal filtration rate, but is independent of insulin secretion or action. Dapa reduces the glucose load filtered by the kidney without affecting other mechanisms which maintain glucose homeostasis, suggesting that dapa may possess a low intrinsic propensity for hypoglycaemia.

Materials and methods: Hypoglycaemic episodes (hypos) were reviewed from four placebo- and one active-controlled Phase 3 studies of dapa in T2DM (Table). In the dapa added to insulin study (NCT00673231), insulin dose could be up-titrated or down-titrated, and in the dapa versus glipizide study (NCT00660907), both treatments were up-titrated and could be down-titrated to achieve glycaemic control. In the dapa added to glimepiride study (NCT00680745), down-titration of the sulfonylurea was permitted in the event of recurrent hypos. In practice, protocol-based guidance on down-titration was not fully applied in these studies. In the remaining studies, treatments remained constant. Total and major hypos were defined as described in the table. Study discontinuations as a result of hypos were also reviewed.

Results: When dapa was used alone or added to metformin, there were no more hypos than placebo, but when added to glimepiride or insulin, there were more hypos than with placebo. In the active comparison study, hypos were more than tenfold less frequent with dapa (3.4%) versus glipizide treatment (39.7%).

Conclusion: The low hypoglycaemic frequency when used alone, or when added to metformin at a fixed dose or titrated, suggests that dapa has a low intrinsic propensity to cause hypoglycaemia in patients with T2DM. Although hypos were more frequent compared with placebo when dapa was added to background glimepiride or insulin, this effect is typically observed in clinical trials where, unlike normal clinical practice, agents with low hypoglycaemic propensity are added to stable doses of a sulphonylurea or insulin.

Background and aims: Inhibition of the sodium glucose co-transporter 2 (SGLT2), the predominant glucose transporter in the proximal tubule of the kidney, has been shown to improve glycaemic control in patients with type 2 diabetes (T2DM) independently of insulin secretion or action. Treatment with dapagliflozin (DAPA), an oral and selective SGLT2 inhibitor under development for the treatment of T2DM, is associated with reductions in hyperglycaemia and modest reductions in body weight (BW), which both have the potential to improve insulin sensitivity and secretion. This study was designed to evaluate changes in these parameters with DAPA.

Materials and methods: This 12 wk randomized, double-blind, placebo-controlled, parallel-group study aimed to assess the effects of once daily 5 mg DAPA on insulin sensitivity as measured by glucose disposal rate (GDR) in subjects with T2DM. Forty four subjects (29 male, 15 female; 36-69 yrs; mean T2DM duration 8.27 ± 6.03 yrs; mean HbA1c 7.52 ± 0.73 %; mean BW 99.38 ± 19.24 kg) on metformin therapy with or without an insulin secretagogue were randomized to receive either DAPA 5 mg QD or matching placebo (PBO). During the 12-wk treatment period, subjects maintained stable doses of background antidiabetic medication. GDR, calculated using the tracers methodology during the last 40 min of a 5 h hyperinsulinemic euglycaemic glucose clamp (HEC), was used as a measure of insulin sensitivity. Insulin secretion was determined as the acute insulin response to glucose (AIRg) during the first 10 min of a frequently sampled intravenous glucose tolerance test.

Results: An increase from baseline (BL) in adjusted mean GDR at Wk 12 was observed with the DAPA group that was significantly different from the PBO group, which showed a decrease. No correction was made for urinary glucose loss, though a sensitivity analysis accounting for urinary glucose loss, measured during the basal step of the HEC, showed similar results. An adjusted mean increase in AIRg at Wk 12 was observed with DAPA treatment relative to BL compared to an adjusted mean decrease with PBO. The difference between the two groups did not reach statistical significance. Consistent with previous studies, a mean reduction from BL in HbA1c was observed at Wk 12 in the DAPA group compared to a slight increase in the PBO group. In addition, mean reductions in BW were observed at Wk 12 in the DAPA group compared with an increase in the PBO group. DAPA was well tolerated by subjects in this study. No subjects in the PBO group and 1 in the DAPA group had hypoglycaemic events, none of which were major or led to treatment discontinuation.

Conclusion: Significant improvement in overall GDR compared with PBO was observed over 12 wks of treatment with the SGLT2 inhibitor DAPA in subjects with T2DM.

Insulin resistance rises from mid-childhood, before the onset of puberty: longitudinal data from The EarlyBird Study

A.N. Jeffery, B.S. Metcalf, J. Hosking, A.J. Streeter, M.B.A. Mostazir, L.D. Voss, T.J. Wilkin;
Endocrinology and Metabolism, Peninsula Medical School, Plymouth, UK.

Background and aims: Insulin resistance is key to the development and control of diabetes. It is known from cross-sectional studies that insulin resistance is higher in puberty, but longitudinal studies are needed to establish at what age the rise begins. Our aim was to document the behaviour of insulin resistance in healthy children aged 5–14y.

Materials and methods: 246 healthy children (141 boys) from the EarlyBird cohort, monitored annually from 5 to 14 years (y) for insulin resistance (HOMA-IR), %fat (DEXA), and self-assessed Tanner Stage (TS; mean genital/breast and pubic hair development). Onset of puberty was defined as TS 2.

Results: The figure shows trends in mean HOMA-IR from 5 to 14y. Insulin resistance began to rise at 7y in boys, 8y in girls. In a linear mixed effects model, insulin resistance rose in boys by 18% (95% CI 15%, 22%), girls 15% (12%, 18%; both $p < 0.001$) over the 4 year period leading up to the onset of puberty, independent of changes in %fat. Insulin resistance continued to rise during puberty in both genders (in girls until TS 4, boys until TS 3, both $p < 0.001$).

Conclusion: The 'pubertal' increase in insulin resistance begins well before pubertal onset, independently of increasing adiposity. The cause of this mid-childhood rise is unclear, but may relate to adrenarche, which typically occurs at 6 to 8y. The period of increased risk for diabetes development, and for increased insulin requirement in those with established diabetes, extends from adolescence back to mid-childhood.

Metabolic consequences of hepatic steatosis in overweight youth

J.M. McGavock¹, B.A. Wicklow¹, K.D.M. Wittmeier¹, A. MacIntosh¹, E.A.C. Sellers², H.J. Dean²;

¹Pediatrics and Child Health, Manitoba Institute of Child Health, ²Pediatrics and Child Health, Winnipeg Children's Hospital, Winnipeg, Canada.

Objective: To determine the association between hepatic steatosis and metabolic risk factors for type 2 diabetes mellitus in adolescents.

Study design and methods: This was a cross-sectional study of 98 overweight adolescents and 11 healthy weight controls aged 13–18yrs. The primary exposure variable was hepatic steatosis defined as hepatic triglyceride ≥ 5.5 mg/g tissue, determined with ¹H-magnetic resonance spectroscopy. The main outcome measures were insulin sensitivity measured by frequently sampled intravenous glucose tolerance test, the presence of the metabolic syndrome, glucose response to an oral glucose challenge and disposition index as a measure of beta cell function. Control variables included visceral fat mass measured with magnetic resonance imaging, physical activity with daily step counts and cardiorespiratory fitness measured with expired gases at the end of the progressive exercise test to exhaustion.

Results: Hepatic steatosis was evident in 31% of overweight adolescents and was associated with lower insulin sensitivity ($p = 0.02$) and a higher prevalence of the metabolic syndrome ($p = 0.001$) compared to youth without steatosis. Clinical features included a higher BMI z-score ($p = 0.02$), and waist circumference ($p = 0.003$). After matching cases and controls for age, sex, and visceral fat mass, those with hepatic steatosis displayed lower insulin sensitivity (3.04 vs 5.10, $p = 0.011$), higher rates of the metabolic syndrome (50 vs 14%, $p = 0.034$), and increased glucose area under the curve (842 vs 754 $p = 0.040$). These differences were not evident when youth were stratified according to visceral fat mass and matched for hepatic triglyceride content. No differences were observed in physical activity, cardiorespiratory fitness or beta cell function between cases with hepatic steatosis and controls with normal hepatic triglyceride content. In multivariate regression analyses, hepatic triglyceride content was a significant predictor of insulin sensitivity ($B = -0.24$, $t = -2.29$, $p < 0.025$), the metabolic syndrome ($B = -0.54$, $t = -5.8$, $p < 0.001$), and glucose area under the curve ($B = 0.33$, $t = 3.3$, $p < 0.001$) independent of visceral and whole body adiposity.

Conclusion: We provide novel evidence that hepatic steatosis is an early biomarker for T2DM in overweight adolescents independent of visceral and whole body adiposity.

Prevalence and risk factor of childhood overweight and obesity in primary school children of Dhaka city

S. Sultana¹, A. Hussain², L. Ali³;

¹Dept of Health Education & Health Promotion, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh, ²General Practice & Community Medicine, University of Oslo, Norway, ³Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh.

Background and aims: Childhood obesity has become a serious public health problem because of its strong association with adulthood obesity and the related adverse health consequences including development of diabetes. Epidemiological data on childhood obesity is virtually nonexistent in Bangladesh. Obesity is strongly associated with insulin resistance, which, when coupled with relative insulin deficiency, leads to the development of overt type 2 diabetes mellitus. The aim of the present study is to determine the prevalence of childhood overweight and obesity and its risk factors in Bangladeshi urban primary school children.

Materials and methods: A cross-sectional study was conducted in primary school children. This study included 1200 participants (both boys and girls aged 6 to 13 years old) collected by following a simple random procedure. On the basis of predefined scoring, subjects were classified as underweight, normal, overweight and obese if their weight-for-height values were within the following ranges of the recommended median values (<90.99% under weight, 91–110% normal weight, 111–120% overweight and > 120% obese). Univariate multinomial regression models were used to estimate the odds ratios (ORs) and the 95% confidence intervals (95% CI). Multivariate multinomial regression models were used to estimate adjusted OR and the 95% CI for three categories of weight-for-height.

Results: The prevalence of overweight was found to be 13.2% (95% CI: 11.33 – 15.17) and obesity 17.8% (95% CI: 15.59 – 19.91) among the study subjects. The prevalence of overweight and obesity among boys were 13.6% (95% CI: 10.83 – 16.41), 22.1% (95% CI: 18.69 – 25.45) and among girls these were 12.9% (95% CI: 10.26 – 15.54) and 13.7% (95% CI: 11 – 16.42), respectively. There were significant difference found in weight for height ($p = 0.015$) and weight ($p < 0.001$) between boys and girls. Mean fat intake of the obese group was significantly higher in overweight and underweight group ($p = 0.008$). The odds for obesity were higher for boys than their counterparts. The study showed that associated risk factor for developing obesity was 1.65 times higher for boys compare to the girls ($p = 0.003$ and CI% 1.19–2.29). The household monthly income and parents education has a significant risk for obesity, even after being adjusted with, age, income, parent's education and physical activities compared to the reference groups. Mean fat intake of the obese group was significantly higher compared to the overweight and underweight groups ($p = 0.008$). Fat intake was significantly and positively associated with the children's weight for height.

Conclusion: The data suggest a high prevalence of overweight and obesity in urban primary school children in Bangladesh. Positive energy balance with higher fat intake, high income of the family and higher education level of the parents (probably reflecting higher socioeconomic class) seem to be among

the major underlying factors for the increased prevalence of childhood obesity in this society.

Prevention of diabetes and obesity in children and teenagers through the Coubertin educational model

M.E. Martínez;

Instituto Coubertin, Oaxaca, Mexico.

Background and aims: Bad eating habits, little exercise and a sedentary life style lead to overweight and obesity among children and teenagers. The later risk factors of diabetes at an adult age. That is why, the 2004 Geneva Declaration of the WHO suggested actions to be carried out in the school setting for the prevention of diabetes and obesity. In August 2005, the Coubertin Educational Model (Oaxaca, México) was set off. Based on both constructivism and humanism, this educational method integrates academic, sport, nutritional and psychological instruction seeking to promote life-lasting habits (a balanced diet, exercise and a healthy life style) that lead to the prevention of obesity, diabetes and associated illnesses.

Material and methods: 675 students were included (454 of elementary and 221 of junior high), from different school years (SY): 70 from 2005–2006, 195 from 2006–2007, 131 from 2007–2008, 122 from 2008–2009 and 157 from 2009–2010. At the beginning and end of each school year both medical and physical aptitude tests were carried out. Along the school cycle, students took daily sport sessions structured in such a way that they were strictly evaluated and graded. Students would also get medical, nutritional and sport assistance. The cafeteria had a strong control on the quality of the food provided to the kids.

Results: In the 2005–06 school year the prevalence of obesity went down from 18.5% to 7.1% and that of overweight fell from 20.0% to 14.2%. In the 2006–07 SY, obesity decreased from 14.2% to 5.7% and overweight went down from 18.6% to 7.2%. In the 2007–08 school year, obesity moved from 16.6% to 6.2% and overweight diminished from 27% to 16.6%. Next school year, 2008–09 obesity started at a rate of 13.2% and finished at a rate of 4.5% while overweight cut down almost by half by going from 14.2% to 7.6%. Last school year, 2009–2010 obesity started from some 10% and came down to only 2.5% whereas overweight flew from 12% to 5%. When the 2005 school year began 70% of the students were consuming too much sugar, 58.57% were eating an excess of fats while only 24.28% of them were including enough vegetables in their daily diets. Soda was a main source of liquids in 80% of the students. Finally, around two thirds of the pupils (62.85%) watched TV for more than 3 hours a day in contrast with just a third (31.42%) who practiced a regular physical activity three or more times a week. By 2010 changes in that group are outstanding: Only 9.2% of the students keep having an excess of sugar in their diets whereas 14.0% continue consuming too much fat. In contrast, all of them (100%) include vegetables in their menus nowadays and none drink soda. Finally, just a fifth (19.14%) spends more than three hours a day in front of the TV set while all of them (100%) exercise three or more times a week. Facts for the 2006, 2007, 2008 and 2009 groups are about the same.

Conclusions: In this study, the Coubertin Educational Model established good eating habits, regular exercise and a healthy life style which brought down both obesity and overweight among students and therefore proved to be an effective way to reduce the risk of diabetes.

859

HbA_{1c} does not detect glucose impairment in youth

J. Hosking, B.S. Metcalf, A.J. Streeter, M.B.A. Mostazir, A.N. Jeffery, L.D. Voss, T.J. Wilkin;

Endocrinology and Metabolism, Peninsula Medical School, Plymouth, UK.

Background and aims: An HbA_{1c} threshold of $\geq 6.5\%$ has been adopted by the ADA to diagnose diabetes in adults, and of $\geq 5.7\%$ to identify individuals at risk. Little, however, is known of HbA_{1c}'s behaviour or diagnostic value in youth. Our aim was to evaluate the diagnostic value of HbA_{1c} in youth at risk of diabetes.

Materials and methods: HbA_{1c} (DCCT aligned) and glucose were measured annually in 274 children from the age of 5y to 14y. Both cross-sectional association and longitudinal trends were examined. ROC analysis was used to determine the diagnostic value of HbA_{1c} in those individuals who had impaired fasting glucose (IFG - glucose $\geq 5.6\text{mmol/l}$).

Results: Cross-sectionally, there were positive associations between HbA_{1c} and glucose ($r = 0.11 - 0.30$, $p = 0.07 - < 0.001$). However, from age 10y HbA_{1c} fell (Figure) while glucose rose ($p < 0.001$). Some 64 observations recorded IFG between 10 and 14y, but HbA_{1c} exceeded 5.7% in only four of them. The area under the ROC curve was modest at 0.67 ($p < 0.001$). Sensitivity and specificity for predicting IFG were optimal at 52% and 76% respectively, corresponding to an HbA_{1c} of 5.4%.

Conclusion: HbA_{1c} is not diagnostically useful in youth at risk of diabetes (IFG). Although HbA_{1c} retains a positive association with glucose over time, their trends from 10y are opposite in direction, suggesting that factor(s) beside glycaemia influence(s) the variance of HbA_{1c} in youth.

Intensified insulin therapy: an additional burden for young children with type 1 diabetes and their families?

C.E. de Beaufort¹, K. Lange², J. Aman³, F. Cameron⁴, L. Castano⁵, H. Dorchy⁶, L. Fisher⁷, H. Hoey⁸, E. Kaprio⁹, M. Kocova¹⁰, Hvidoere Study Group;

¹DECCP, Clinique pédiatrique, Luxembourg, ²Medizinische Psychologie, Medizinische Hochschule Hannover, Germany, ³Department of Paediatrics, Örebro University Hospital, Örebro, Sweden, ⁴Department of Endocrinology & Diabetes, Royal Children's Hospital, Parkville Vic, Australia, ⁵Endocrinology and Diabetes Research Group, Hospital de Cruces, Barakaldo, Spain, ⁶Diabetology Clinic, Hôpital Universitaire Reine Fabiola, Brussels, Belgium, ⁷Diabetes&Endocrinology, Childrens Hospital of Los Angeles, Los Angeles, USA, ⁸Trinity College, National Childrens Hospital, Dublin, Ireland, ⁹Dept of Pediatrics, Peijas Hospital, Hus, Finland, ¹⁰Department of Endocrinology & Genetics, University Clinic, Skopje, Macedonia

Objective: Compare quality of life of young children with type 1 diabetes (T1DM) and their parents' well-being with intensified (IT:CSII + ICT) or conventional insulin (CT) therapy.

Methodology: In a cross sectional study, all children of 18 centres in North America Australia, Europe and Japan, age <11 yrs with a diabetes duration (DD) ≥ 1 y, and their parents, were invited to participate. Information on clinical characteristics, treatment, severe hypoglycaemia and diabetic ketoacidosis were collected. HbA_{1c} was measured centrally by ¹⁸Tosoh liquid chromatography (DCCT aligned normal range 4.4–6.3%). Quality of Life (QoL) was evaluated by kidscreen index (≥ 7 years); kidscreen-27 proxy (physical well-being, psychological well-being, autonomy and parent relation, social support and peers, school) and WHO-5 for parents.

Results: In total 1133 children participated: IT (n=562, 47.4% F, age 8.1 ± 2.1 y, CT n=570; 48% F; age 7.9 ± 2.1 y). Diabetes duration in the IT was significantly longer (3.6 ± 2.9 vs 3.1 ± 2.0 yrs) with a significantly lower HbA_{1c} (7.9 ± 0.9 vs 8.1 ± 1.1 %) and less hypoglycaemic events (.02 vs .05). Children with diabetes overall do not differ from norm data of healthy peers in any of the QoL dimensions. A significantly better QoL was reported in the IT group ($< .02$) on all subscales of kidscreen questionnaire, except psychological well being. Parent well-being did not differ between the two groups.

Conclusion: In this large international crosssectional study, IT in young children with T1DM results in an improved metabolic outcome, less hypoglycaemia and in 4/5 dimensions better quality of life, suggesting that intensification of therapy can be started early onwards.

Evaluation of 3 bolus calculators in children and adolescents with type 1 diabetes using insulin pump therapy

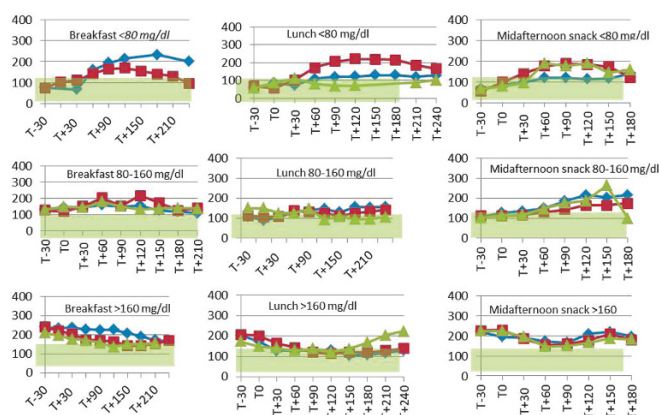

A.E. Scaramuzza, L. De Angelis, A. Gazzarri, A. Bosetti, F. Platerote, F. Redaelli, M. Macedoni, S. Mazzantini, O. Marchi, D. Maio, A. De Palma, G. Zuccotti;
Paediatrics, University of Milano - Luigi Sacco Hospital, Italy.

Background and aims: Recently, pump manufacturers have engineered a new feature called 'bolus calculator', which calculates bolus insulin doses based on input from the pump wearer, which functions to help patients obtain optimum control over blood glucose levels. The bolus calculator takes into account the patient's current blood glucose, target blood glucose, amount of carbohydrate consumed, and other factors such as insulin sensitivity and insulin-to-carbohydrate ratio as well as duration of insulin action. Each pump company calculates insulin doses in a slightly different way. The aim of this study is to compare the efficacy of three bolus calculators (Animas 2020, Animas, Accu-Chek Combo, Roche, Paradigm Veo, Medtronic) to safely reduce postprandial hyperglycemia in children and adolescents with type 1 diabetes using insulin pump therapy.

Materials and methods: We enrolled 22 patients, aged 9–22 yrs. (mean 16.2 ± 4.9 yrs.) with type 1 diabetes from 1 to 18 yrs. (9.1 ± 4.1 yrs.), BMI 21.9 ± 4.5 kg/m², using insulin pump therapy for more than 6 months (insulin requirement 0.86 ± 0.27 U/kg/day, HbA1c $8.3 \pm 0.9\%$). For each patient we studied on 3 occasions (order of bolus calculator used randomly assigned) 3 different meals (breakfast, lunch and midafternoon snack); their composition was exactly the same in terms of quality and quantity on the 3 days. Insulin bolus, was injected 15 min prior meal. Patients checked glycaemia 30 minutes before meal and every 30 minutes for the following 4 hours. In case of hyperglycaemia after 2 hours from meal, a correction bolus was calculated using the bolus calculator assigned for that day.

Results: Data are shown in the table. The performance of the 3 bolus calculators was similar and did not show any statistical difference among them ($p=0.278$ by ANOVA). In case of pre-prandial hyperglycaemia or hypoglycaemia, Medtronic bolus calculator showed the best performance on average when compared with both Animas and Roche bolus calculators ($p=0.003$ for hypo and $p=0.041$ for hyper, respectively).

Conclusion: Bolus calculator seems a good feature to improve insulin pump therapy performance in children and adolescents with type 1 diabetes. No significant difference has been observed among the 3 different ones tested. However, when in hyperglycaemia, it is wise to separate the correction bolus from the meal bolus (to be injected 30 min prior the meal, and 15 to 20 min prior the meal bolus). Table - Glycaemic values (mg/dl) after using 3 different bolus calculator (Animas, A n=22, Medtronic, M n=22, and Roche, R n=18) after breakfast (B), lunch (L) and mid-afternoon snack (MS), according to different pre meal glycaemic ranges. *by ANOVA; ** $p=0.003$ by Kruskal-Wallis (among groups); $p=0.041$ by Kruskal-Wallis (among groups).

Effectiveness and safety study of the prototype 4th generation seven day continuous glucose monitoring system in youth with type 1 diabetes mellitus

B. Buckingham¹, K. Nakamura², K. Benassi¹, J. Realsen³, D. Liljenquist⁴, P. Chase⁵;

¹Pediatrics- Endocrinology and Diabetes, Stanford University, Stanford, ²Dexcom, Inc, San Diego, ³Barbara Davis Center For Childhood Diabetes, Aurora, ⁴Rocky Mt. Diabetes and Osteoporosis Center, Idaho Falls, USA.

Background and aims: Real-time continuous monitoring systems have been available to obtain better glycemic control in adult patients with diabetes. However, youth with type 1 diabetes are thought to have rapid glucose changes and to bring more challenge to the system user interfaces. The purpose of this study is to evaluate the effectiveness and safety of a prototype 4th generation of 7 day CGM system when worn by youth (6 to <18 years-old) with type 1 diabetes mellitus.

Materials and methods: 72 youth at 3 US centers were studied to test the performance of the prototype 4th generation 7 day CGM system. Subjects were scheduled for three consecutive 7-day wear periods (new sensor for each period, one masked and two unmasked periods). The OneTouch® Ultra2® meter was used for CGM system calibrations and diabetes management and subjects were instructed to use the CGM system information as an adjunct to their blood glucose (BG) meter readings. During the unmasked home use period, subjects were provided CGM glucose values and trend graphs and were asked to confirm high and low system alerts/alarms by taking a BG reading immediately after receiving a CGM alert/alarm.

Results: 70 subjects (97%) completed all visits. 37 subjects (51.4%) enrolled were male; 98.6% were White. The mean \pm SD (range) age of the enrollment population studied was 12.6 ± 2.8 (6.1 to 17.6) yrs. The mean \pm SD duration of diabetes was 6.3 ± 3.7 yrs. 59 subjects (81.9%) used CSII for insulin therapy; 13 subjects (18.1%) were on MDI therapy. The mean \pm SD baseline HbA1C was $8.26 \pm 1.49\%$. Over three 7-day wearing periods, there were no serious adverse events, sensor fractures, or infection complications. Except for infrequent mild (12.0%) or moderate (1.2%) skin irritations at the sensor insertion and adhesive sites, no other device related adverse events were occurred. 82% sensors lasted till day 6 and 74% sensors lasted till day 7. A total of 6466 paired CGM sensor and meter glucose values were obtained. 75.6% (95%CI: 72.7%-78.4%) of CGM sensor measurements were within 1.1 mmol/l of SMBG (for value ≤ 4.4 mmol/l), and 74.4% (95% CIs: 73.2%-75.5%) of CGM sensor measurements were within 20% of SMBG (for value > 4.4 mmol/l). The overall mean and median Absolute Relative Differences (ARD) vs. SMBG were 16.3% and 12.0%, respectively. During the unmasked phase and based on the subject's BG results, the true alert rates were 88.3% at the high alert level of 11.1 mmol/l and 67.0% at the low alert level of 4.4 mmol/l. There was a statistically significant improvement in time spent in euglycemia (3.9–10.0 mmol/l) for the two weeks when sensor readings were unmasked with an average improvement of 1.2 hrs/day (95%CI: 0.6–1.9 hrs/day, $p<0.001$).

Conclusion: The study concludes that the duration of diabetes, age, sex and BMI showed no significant impacts on the system performance and there were no significant system performance differences between study centers or with masked vs. unmasked wear. The accuracy, alert rates, and sensor life of the prototype 7 day CGM in youth were similar to that of adult patients and compared favorably to the CGM system currently approved for pediatric use. Youth with type 1 diabetes had improved time spend within target range even with a short term CGM display wear.

Association of epilepsy and type 1 diabetes in children and adolescents

E. Schober¹, B. Rami¹, K.P. Otto², A. Dost³, N. Jorch⁴, R.W. Holl⁵, German/Austrian DPV Initiative and the BMBF competence network diabetes;

¹Department of Pediatric and Adolescent Medicine, Medical University Vienna, Austria, ²Wilhelmstift Catholic Children Hospital, Hamburg, Germany, ³Department of Pediatrics, University of Jena, Germany,

⁴Department of Pediatrics, Evang. Krankenhaus Bielefeld, Germany, ⁵Institute of Epidemiology, University of Ulm, Germany.

Background and aims: An association between diabetes and idiopathic generalized epilepsy has been described in adult patients. The aim of the investi-

gation was to estimate the prevalence of epilepsy and possible risk factors in diabetic children and adolescents.

Materials and methods: In an observational cohort study based on the DPV-database (German/Austrian DPV initiative) data from 45 851 patients (52 % male) with type 1 diabetes (<20 years) could be analyzed. The mean age was 13.9 ± 4.3 years (mean \pm SD) and the mean duration of diabetes 5.4 ± 4.2 years. To ensure that all possible epilepsy cases were identified, the data base was searched for the concomitant diagnosis epilepsy or epileptic convulsions and for antiepileptic medication.

Results: 705 patients with epilepsy were identified giving a prevalence of 15.5/1000. 375 patients were treated with antiepileptic medication, while 330 were without anticonvulsive therapy. Patients with epilepsy were younger at onset of diabetes (7.7 ± 4.1 vs 8.5 ± 4.3 yrs, $p < 0.01$) and shorter than patients without epilepsy (height-SDS -0.22 ± 1.28 vs -0.05 ± 1.04 , $p < 0.05$), while weight and BMI were comparable. Comparing patients with epilepsy currently on antiepileptic drugs (AED) with patients without AED height reduction was primarily observed in the patients on AED treatment (height-SDS -0.47 ± 1.26 vs $+0.05 \pm 1.1$, $p < 0.01$). No difference between patients with and without epilepsy could be demonstrated for metabolic control, type of insulin treatment, insulin dose and prevalence of B-cell specific autoantibodies. The risk for DKA was almost double in patients with epilepsy compared to patients with type 1 diabetes alone (DKA per 100 patient years 10.5 ± 1.46 vs 5.6 ± 0.14 , $p < 0.01$).

Conclusion: Diabetic children and adolescents show an increased prevalence of epileptic seizures compared to reported prevalence rates in non-diabetic children. Due to unknown reasons there seems to be an association between DKA risk and epilepsy in diabetic children and adolescents.

864

Direct diabetes-related costs in young patients with early onset and long-lasting type 1 diabetes

C. Bächle¹, K. Straßburger¹, A. Hungele², P. Beyer³, R. Ziegler⁴, U. Schimmel⁵, R. Lepler⁶, A. Schumacher⁷, M. Holder⁸, M. Grabert², A. Stahl¹, A. Icks^{1,9}, J. Rosenbauer¹, R.W. Holl²;

¹German Diabetes Center, Düsseldorf, ²University of Ulm, ³Evangelisches Krankenhaus Oberhausen, ⁴Pediatric Diabetologist, Münster, ⁵Allgemeines Krankenhaus, Hagen, ⁶Katholisches Kinderkrankenhaus Wilhelmstift, Hamburg, ⁷Klinik Am Eichert, Göppingen, ⁸Klinikum Stuttgart, Olghospital, Stuttgart, ⁹Heinrich-Heine-University, Düsseldorf, Germany.

Background and aims: The incidence of type 1 diabetes (T1DM) is increasing worldwide, especially in younger children. Children with early onset of diabetes bear a greater life-time risk of developing diabetic complications and may cause higher costs than average. The aim of this study was to estimate diabetes-related direct costs of pediatric T1DM and their predictors in young German patients with early onset (0–4 years) and at least ten years diabetes duration.

Materials and methods: Data of 1,473 patients with diabetes onset at the age of 0–4 years during the period 1993–1999 and continuous documentation of treatment during 2006–2008 were included. Patients were 53% male, mean age (SD) was 13.42 (2.21) and mean diabetes duration (SD) 10.44 (1.94) years. Mean HbA1c of the study cohort was 8.1%. All diabetes-related health care services during the year 2007 were derived from a nationwide prospective documentation system (DPV). The study took the perspective of the statutory health insurance. For the analysis of direct diabetes-related costs, health care utilization was valued in monetary terms using inpatient and outpatient medical fees and retail prices. We estimated the association between total diabetes-related costs as well as different cost categories (dependent variables) and age, sex, diabetes duration, metabolic control, and migration background applying multiple regression models. Mean direct costs were compared to average costs of 12,001 prevalent T1DM patients less than 20 years of age and shorter diabetes duration (mean age: 12.1 years, mean duration: 4.7 years) in Germany.

Results: Mean diabetes-related direct costs were Euro 3,774 (quartile 1: 1,930, quartile 3: 4,988) per patient-year. Glucose-self monitoring was the main cost category (29.4%), closely followed by CSII (25.8%, pump and catheters), diabetes-related hospitalizations (21.9%), and insulin (18.2%). Other cost categories (diabetes-related ambulatory care, needles/syringes, glucagon sets, other medication) amounted each at most 2%. Total costs were 6.5% lower in males ($p=0.022$) and 8.9% lower in patients with migration background ($p=0.031$). They increased with poor metabolic control (HbA1c 7.5–9: +8.3% ($p=0.015$), HbA1c >9: +14.1% ($p=0.001$)). A diabetes duration >11 years compared to a shorter duration and an age >15 years versus 8–11 years did

not significantly affect total medical costs. However, costs were significantly higher in youths aged 12–15 years. Average costs were 7.6% higher than mean diabetes-associated costs of prevalent T1DM patients with shorter diabetes duration (Euro 3,507).

Conclusion: Female gender, pubertal age, and poor metabolic control were significantly associated with increased costs. Although average diabetes duration in this cohort was >10 years, mean diabetes-related direct costs were only slightly increased compared to costs in a cohort with shorter diabetes duration in Germany.

Children of higher income families eat 'better' and are taller, but they are metabolically less healthy

M.B.A. Mostazir, B.S. Metcalf, J. Hosking, A.J. Streeter, A.N. Jeffery, L.D. Voss, T.J. Wilkin;
Early Bird Study, Peninsula Medical School, Plymouth, UK.

Background and aims: It is a widely held belief that children from higher income families eat 'better', and are metabolically healthier as a result. However, like many such beliefs, the notion has largely gone untested. We have used objective measurement and fasting blood samples from a large cohort of children to test the relationships between body composition, metabolic health and diet. We hypothesised that children of higher income families would eat better, and would be slimmer and metabolically healthier as a result.

Materials and methods: Factor analysis (promax) was carried out on a 45-item food frequency questionnaire to establish the distribution of food choice (expressed as z-scores) among 307 9y-old children (n=170 boys, 137 girls) from the EarlyBird cohort. Height was measured in duplicate by stadiometer, % body fat by dual-energy x-ray absorptiometry (DEXA), subcutaneous fat by the sum of five skinfold thicknesses, and metabolic health by HOMA2-IR and serum leptin. The children were grouped according to family income.

Results: Two principal dietary components emerged, 'elemental' (E: fish, meat, vegetables, rice, pasta etc) and 'processed' (P: crisps, chips, sausage, chocolate, white bread etc.). 'E' foods were more frequently consumed by children of higher income families (mean difference = 0.44 z-scores, $p < .001$) and 'P' foods more frequently by children of lower income families (mean difference = 0.22 z-scores, $p < .001$). Consumption of 'E' foods was also associated with height. Thus, in a fully adjusted model controlling for family income, parental education and child gender, one unit (z-score) difference in 'E' food consumption was associated with 1.4 cm in height ($p < .05$). Taller children, however, were both fatter and metabolically less healthy. Accordingly, a unit difference in height was associated with 0.07 BMI SDS ($p < .001$), 0.60 % body fat ($p < .001$), 0.01 cm subcutaneous fat ($p < .001$), 0.03 units insulin resistance ($p < .001$) and 0.40 ng/ml serum leptin ($p < .001$).

Conclusion: Higher income families eat more elemental foods, and children who eat elemental foods are taller. Contrary to our hypothesis, however, such children tend to be fatter and metabolically less healthy. Protein over-nutrition among wealthier families may be one explanation.

Prospective associations between dietary insulin index, glycaemic index and glycaemic load during puberty and body composition in young adulthood

A.E. Buyken¹, G. Joslowski¹, J. Goletzke¹, G. Cheng¹, A.L.B. Günther², J. Bao³, J.C. Brand-Miller³;

¹Nutrition and Health, Research Institute of Child Nutrition, Dortmund, Germany, ²Fulda University of Applied Science, Germany, ³University of Sydney, Australia.

Background and aims: Puberty is a so-called critical period for overweight and characterized by physiological insulin resistance during mid-puberty. This study addressed the hypothesis that habitual consumption of a diet inducing higher levels of postprandial glycemia or insulinemia during puberty may have an unfavorable effect on body composition in young adulthood.

Materials and methods: Multivariate regression analysis was performed on 263 DONALD participants with at least two 3-day weighed dietary records during puberty (girls 9–14 years; boys 10–15 years) and anthropometric measurements in young adulthood (18–25 years). A published dietary glycemic index (GI) was assigned to each carbohydrate containing food. Similarly, each food was assigned a food insulin index (insulinemic response to a 1MJ portion of food relative to 1MJ of white bread) using 121 values measured at Sydney University.

Results: Dietary GI or glycemic load during puberty were not related to body composition in young adulthood. The dietary insulin index (II) during puberty was associated with higher levels of percentage of body fat (%BF) in young adulthood, even after adjustment for early life, socioeconomic and nutritional factors; %BF in energy-adjusted tertiles of dietary II were 23.1 (95%CI: 21.9, 24.4), 24.4 (23.2, 25.7), 24.8 (23.6, 26.0) (p for trend=0.02). Ad-

justment for baseline %BF attenuated this relationship (p for trend=0.1). Dietary II was not related to BMI.

Conclusion: This study suggests a prospective adverse influence of dietary II during puberty on body fat in young adulthood. Postprandial increases in insulinemia rather than increases in glycemia appear to be implicated in an unfavorable development of body composition.

The role of glycaemic index and glycaemic load on weight loss and on the metabolic parameters of adults with type 2 diabetes

V. Argiana¹, P. Kanellos², I. Eleftheriadou¹, K. Alexiadou¹, P. Grigoropoulou¹, G. Tsitsinakis¹, I. Balla¹, A. Kokkinos¹, D. Perrea¹, N. Tentolouris¹;

¹First Department of Propaedeutic Medicine, Athens University Medical School, Laiko General Hospital, ²Dietetics and Nutrition, Harokopio University of Athens, Greece.

Background and aims: The aim of the present study was to examine the effects of consumption of desserts with low glycaemic index (GI) and low glycaemic load (GL), as part of a balanced hypo-caloric diet, on glycaemic control and weight loss in patients with type 2 diabetes mellitus.

Materials and methods: A total of 48 overweight or obese adults with type 2 diabetes treated with oral antidiabetics were studied. The subjects were randomly assigned in two groups. The first group included 25 subjects [intervention group, mean age 61 ± 8 years, men/women (n) 9/16] and the second one 23 [control group, mean age 62.6 ± 7.6 years, men/women (n) 15/8]. Both groups followed the same hypo-caloric diet for three months under supervision of a clinical dietitian. The desserts of low GI/GL were included in the diet in the intervention group and they were allowed to consume 4 desserts/week, while no desserts were allowed in the control group. All participants underwent a complete clinical and biochemical evaluation at baseline and after the 3 months. Additionally, at the end of the three month period, subjects of both groups consumed in two different days two isocaloric desserts (a dessert of low GI/GL and a common high GI dessert) after 10–12 hours fasting and blood samples were collected before and 30, 60, 90, 120 min after consumption of the desserts. Afterwards, they were asked to evaluate the degree of preference, hunger and satiety as well as potential side effects of the desserts consumed.

Results: In the intervention group, HbA_{1c} ($p=0.015$), fasting blood glucose ($p=0.01$), body weight ($p<0.001$), body mass index (BMI) ($p<0.001$), waist circumference ($p<0.001$), hip circumference ($p<0.001$), blood pressure ($p<0.03$), SGPT ($p=0.02$) and γ GT ($p=0.04$) decreased significantly and there was a trend for a decrease in CRP ($p=0.09$) at 3 months in comparison with baseline. In the control group, there was a trend for decrease in HbA_{1c} ($p=0.08$), while weight, ($p<0.001$), BMI ($p<0.001$), waist ($p<0.001$) and hip ($p<0.001$) circumference and SGOT ($p=0.049$) decreased significantly at 3 months in comparison with baseline. At three months, the intervention group in comparison with the control group showed greater improvement in body weight ($p=0.05$), BMI ($p=0.032$), diastolic blood pressure ($p=0.03$), γ GT ($p=0.04$) and CRP ($p=0.02$). The area under the curve of blood glucose during the 2-hour period was significantly lower after consumption of the dessert of low GI/GL in comparison with the consumption of the common dessert ($p<0.001$). Moreover, the degree of preference and the feeling of hunger or satiety were not different after consumption of the two different desserts. Furthermore, 2.1% of the subjects who consumed the low GI/GL dessert and none of those who consumed the common dessert reported gastrointestinal side effects.

Conclusion: Consumption of desserts with low GI/GL in a balanced hypo-caloric diet has a positive impact on weight loss and improves metabolic parameters of patients with type 2 diabetes mellitus.

A low-carbohydrate protein sparing modified fast diet compared with a low glycaemic index reduced calorie diet in obese type 2 diabetic patientsD. Vlachos¹, A. Ganotopoulou², C. Stathi³, A. Koutsovalis³, E. Diakoumopoulou³, D. Doulgerakis³, N. Tentolouris³, A. Melidonis², N. Katsilambros³¹Eurodiet Med, Athens, ²Diabetes Center, Tzanio General Hospital, Athens,³1st Department of Propaedeutic and Internal Medicine, Athens University Medical School, Laiko General Hospital, Greece.

Background and aims: Low-carbohydrate (LCD) and protein sparing modified fast diets (PSMF) seem intuitively attractive due to their potent antihyperglycemic effect while low-glycemic reduced calorie diets (LGID) are more common. This study aims at evaluating and comparing the effect of a LCD/PSMF diet with a LGID on the improvement of weight-related components, glycemic control and lipidemic profile in obese type2 diabetes patients.

Materials and methods: Seventy two type 2 diabetic patients [(32%) men, and (68%) women], 54.41±8.48 years old, BMI > 30 Kg/m² and type2 diabetes were randomized to either a LCD/PSMF ketogenic diet (800kcal/day progressively increasing to 1200kcal/day) or a low-glycemic index diet, reduced-calorie diet (500 kcal/day deficit from weight maintenance diet). All patients received group meetings, and exercise recommendation. Participants were encouraged to exercise for 30 minutes at least 5 times/week. At baseline and at all return visits participants recorded all of their current medications. Body weight, BMI, fat mass, fat-free mass, total cholesterol, LDL, HDL, triglycerides (TGs) and HbA1c were determined before and at 2, 9 and 22 weeks after the administration of each diet.

Results: Nine participants out of 40 and 8 out of 39 randomized to the LCD/PSMF and LGID group respectively, discontinued the study leaving 31 in the LCD/PSMF group and 32 in the LGID group for the analyses. Both interventions led to improvements in HbA1c, fasting glucose, fasting insulin and weight loss. At 22 weeks time interval the reduction of mean HbA1c was greater for the LCD/PSMF group (8.8 ± 1.8% to 7.3 ± 1.5%, p = 0.009) than for the LGID group (8.3 ± 1.9% to 7.8 ± 2.1% p= NS, between groups comparison p = 0.03). Reduction in fasting glucose was also greater in the LCD/PSMF (47.97±17.21 vs 24.13±12.21, p=0.021) than in the LGID group. Reduction of body weight was significant in the LCD/PSMF group (109.74±20.73 vs 93.81±19.13, p=0.001) but nonsignificant in the LGID group (103.50±14.84 vs 98.54±14.64, p=0.191). Waist circumference was significantly reduced in the LCD/PSMF group (131.28±12.70 vs 100.93±13.42, p<0.001) but not in the LGID group (126.66±9.34 vs 114.60 ±7.79, p=0.186). Only in the LCD/PSMF group there was a significant reduction in body fat mass (47.41±11.35 vs 34.70±10.40, p<0.001), in total cholesterol (p=0.001), in TGs (p=0.014), and in diastolic blood pressure (0.041) as well as a significant increase in HDL (0.036). All these improvements were statistically significant from the 9th week after the introduction of the LCD/PSMF diet. There was also a significant reduction in the insulin units in the LCD/PSMF group (60±32 vs 28±12 IU/day, p=0.022).

Conclusions: The LCD/PSMF diet compared to a LGID results: a) in a significantly greater weight loss, b) in a better glycemic control and lipidemic profile, c) greater reduction of BP and d) reduction and/or eliminate of medication.

Specific nutrients, foods and risk of type 2 diabetes in subjects with IFG: the DR's EXTRA StudyH.M. Heikkilä^{1,2}, U. Schwab^{2,3}, B. Krachler¹, R. Kouki¹, R. Rauramaa^{1,4},¹Kuopio Research Institute of Exercise Medicine, ²School of Medicine, Clinical Nutrition, University of Eastern Finland, Kuopio Campus, ³Institute of Medicine, Kuopio University Hospital, ⁴Clinical Physiology and Nuclear Medicine, Kuopio University Hospital, Finland.

Background and aims: Insulin resistance and impaired insulin secretion, major pathophysiological mechanisms for Type 2 Diabetes (T2D), have both been found to be present in impaired fasting glucose (IFG). IFG precedes the development of T2D. Besides the effect of diet and physical fitness on insulin resistance, there are also findings of diet being linked to improved insulin secretion. However, currently only scarce data are available on the association of dietary factors and IFG. We therefore studied the association of selected food items and nutrients with IFG independent of cardiorespiratory fitness.

Materials and methods: The subjects were participants of our 4-year randomized controlled exercise and diet intervention study, The DR's EXTRA trial (ISRCTN45977199). We identified 126 subjects (84 men and 42 women) with IFG in our population based sample of 1261 individuals of 633 women and 628 men aged 57 - 79 years. IFG was defined as fasting plasma glucose 6.1-6.9 mmol/l and 2h plasma glucose < 7.8 mmol/l. Dietary intake was assessed by 4-day food records. Selected dietary factors for analysis were as follows: dietary fiber, saturated fat, polyunsaturated fat, cereal products, whole meal bread, fruits, berries, vegetables, butter, cheese, sausage, vegetable oil and sugar. Associations between dietary factors and glucose metabolism status were studied by logistic regression analysis. Data were adjusted for age and maximal cardiorespiratory fitness (VO₂max). Results are expressed as OR; 95 % CI. **Results:** Dietary fiber intake (g/1000kcal) was associated with decreased risk for IFG (OR 0.94; CI 0.90-0.99). The highest tertile of cereal products was also associated with decreased risk for IFG (OR 0.53; CI 0.32-0.87). Furthermore, the highest tertile of whole meal bread was associated with decreased risk for IFG (OR 0.48; CI 0.29-0.78). Saturated fat (E%) was associated with increased risk for IFG (OR 1.08; CI 1.01-1.14). Of the foods contributing to saturated fat intake sausage was associated with increased risk for IFG (OR 1.60; CI 1.06-2.41). Associations between the highest tertile of saturated fat and IFG (OR 1.51; CI 0.95-2.39) and the highest tertile of sausage and IFG (OR 1.48; CI 0.94-2.33) were of a borderline significance (P = 0.082 and 0.087, respectively).

Conclusion: Data suggest that dietary fiber, cereal products and whole grain products are protective against the risk of IFG, whereas saturated fat and foods contributing to saturated fat intake are associated with an increased risk of IFG.

Menstruation dependent blood glucose variation in women with type 1 diabetes mellitusC. Kellner¹, N. Müller¹, C. Kloos¹, G. Wolf¹, J. Weiss², U.A. Müller¹;¹Department of Internal Medicine III, ²Department of Gynecology and Obstetrics, University Hospital Jena, Germany.

Background and aims: Some patients with type 1 diabetes mellitus experience a worsening in metabolic control at the beginning of menstruation. In a detailed German training programme for patients with type 1 diabetes a worsening in blood control with increased risk of ketoacidosis and hypoglycaemia was reported. Increased premenstrual blood glucose levels were discussed and the possible controversial reasons for this are speculative. This study was designed to investigate blood glucose levels and possible influencing factors e.g. pain, nutrition, activity, stress and mood dependent on menstruation.

Materials and methods: 20 menstrual cycles from women with type 1 diabetes mellitus (age 34y; diabetes duration 22y; HbA1c 7.2%, BMI 26kg/m², blood glucose self monitoring 5,9 tests/d, pump therapy 65%) were analysed by means of self monitored blood glucose, insulin dose and food intake. Physical activity and stress were documented using a 3 point Lickert-Scale and pain with a 10 point Lickert-Scale. The mood was measured with the Zersen mental-state-scale. The menstrual cycle can be divided into 3 sections: the menstruation period, with the first day of menstruation as the beginning, then the mid-cycle and thirdly the premenstrual period. Half the women took oral contraceptives. All patients had participated in a structured education in the last 10 years. Clinical and laboratory data were drawn from the electronic patient record. HbA1c was DCCT adjusted (normal mean 5.05%).

Results: In the premenstrual period mean blood glucose was 0.4 mmol/l higher compared to the menstrual period (8.0 vs. 7.6 mmol/l; p=0.04). Caloric intake increased by 8% (1888 kcal vs. 1722 Kcal/d; p=0.03). There was a slight increase in all nutrients: carbohydrates 197g vs. 189g (p=0.29), fat 17g vs. 11g (p=0.08) and protein 68g vs. 61g (p=0.015). No change in the food composition occurred during menstrual cycle. The mean insulin dose was 19 IU/d during the menstrual period, decreased to 18.3 IU/d mid-cycle-period (p=0.03 vs. menstrual period) and increased to 19.9 IU/d in the premenstrual period (p<0.001 vs. Mid-cycle). Pain (score max. 10) was scored higher during menstruation compared to the premenstrual period (1,5 to 0,4 p=0,005). There were no significant differences in documented physical activity, stress or mood. The increase of blood glucose (7.7 to 7.4mmol/l, p=0.35) and caloric intake (1829 vs. 1713 kcal/d, p=0.3) in the premenstrual phase was markedly less in women with oral contraceptives compared to women without (8.4 vs. 7.9 mmol/l, p=0.04; 1941 vs. 1731 kcal/d, p=0.063).

Conclusion: In women with type 1 diabetes we found a slight but significant premenstrual increase in blood glucose levels compared to the other sections of the cycle. This increase in blood glucose was not entirely compensated by the increased insulin dosage. The increase in blood glucose may be caused by increased food intake. No woman complained of premenstrual syndromes, pain, stress or reduction in physical activity. The small increase of blood glucose levels was clinically irrelevant.

871

A diet high in whole grain, fatty fish, and bilberry improves markers of endothelial function and inflammation in individuals with impaired glucose metabolism

V.D.F. de Mello Laaksonen¹, U. Schwab^{1,2}, M. Kolehmainen¹, W. Koenig³, M. Siloaho¹, K. Poutanen^{1,4}, H. Mykkanen¹, M. Uusitupa^{1,5};

¹Department of Clinical Nutrition, Food and Health Research Centre, Institute of Public Health and Clinical Nutrition, University of Eastern Finland, Kuopio, Finland, ²Institute of Clinical Medicine, Internal Medicine, Kuopio University Hospital, Finland, ³Department of Internal Medicine II-Cardiology, University of Ulm Medical Center, Germany, ⁴VTT, Technical Research Centre of Finland, Espoo, Finland, ⁵Research Unit, Kuopio University Hospital, Finland.

Background and aims: Low-grade inflammation and endothelial dysfunction may play a role in the pathogenesis of the metabolic syndrome (MetS), type 2 diabetes mellitus and cardiovascular diseases. We sought to evaluate if a diet high in fatty fish, bilberry, and whole grain products including breads with a low insulin response (“HealthyDiet”) improves biomarkers reflecting inflammation and endothelial dysfunction in individuals with impaired glucose metabolism and features of the MetS.

Materials and methods: Altogether 104 participants (59 ± 7 yrs; BMI: 31.1 ± 3.5 kg/m²) with impaired glucose metabolism (IFG or IGT) and features of the MetS who were randomized to either the “HealthyDiet” (n=36), a Whole Grain-Enriched Diet (WGED, n=34) or a control diet (n=34) for 12 weeks were analyzed. Measurements were taken at baseline and at week 12. Serum hsCRP (high-sensitivity C-reactive protein) concentration was determined by nephelometry and E-selectin concentration by ELISA.

Results: Serum E-selectin decreased in the “HealthyDiet” group in all participants (33.2 ± 13.8 vs. 31.5 ± 13.3 µg/L, % change: -4.2 (-10.1; 1.7); p=0.04) and also after excluding those using statins (n=27) (35.1 ± 15.2 vs. 32.7 ± 14.7 µg/L, % change: -6.7 (-11.5; 1.9); p=0.004). The change in E-selectin was significantly different from the change in the control group (p=0.02). Serum E-selectin did not change significantly in the WGED or in the control groups either in all participants (31.7 ± 10.7 vs. 32.3 ± 12.4 µg/L and 28.5 ± 11.5 vs. 30.0 ± 12.7 µg/L, respectively; p>0.05 for both) or after excluding those using statins (31.7 ± 10.8 vs. 31.7 ± 12.3 µg/L and 30.5 ± 11.8 vs. 32.2 ± 13.0 µg/L, respectively; p>0.05 for both). Serum hsCRP levels decreased in both the “HealthyDiet” (1.9 [0.8; 3.6] vs. 1.1 [0.8; 2.6] mg/L, % change: -16.8 (-40.7; 0.00) p=0.04) and WGED (2.1 (0.7; 4.1) vs. 1.0 (0.6; 2.3) mg/L, % change: -27.2 (-58.6; 0.00); p=0.006) groups in participants not using statins (n=24 and n=25, respectively). Serum hsCRP did not change in the control group (p>0.10) and was significantly different from the change in the WGED group (p=0.03). The increase in the intake of long-chain n-3 fatty acids and fiber during the study were both associated with the decrease in serum E-selectin (β=-0.30 and β=-0.26, p<0.05 for both). The amount of bread with a low insulin response consumed during both the “HealthyDiet” and WGED interventions was associated with the decrease in hsCRP levels (β=-0.51, p<0.001).

Conclusion: Our results suggest that the combined effect of dietary whole grain, fatty fish and bilberries may have a benefit on endothelial dysfunction and inflammation in individuals with impaired glucose metabolism and features of the MetS.

Dietary fibre and glycaemic control in patients with diabetes: a systematic review and meta-analysis of randomised clinical trials

F.M. Silva, C.K. Kramer, T. Steemburgo, J.C. de Almeida, M.J. Azevedo; Endocrine Division, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Background and aims: Increased fiber intake has been associated with improved glycemic control in patients with diabetes and represents a useful dietary tool to reach glycemic targets. The aim of this study was to assess the effect of fiber intake on glycemic control of patients with diabetes by a systematic review and meta-analysis of randomized controlled trials (RCT).

Material and methods: To identify RCTs that report the effect of fibers on HbA1c and fasting plasma glucose (FPG) (outcomes) the Pubmed, Embase, and Scopus databases were searched up to January, 2011. Reference lists of retrieved articles were also checked. Search strategy included medical subject headings related to diabetes, fiber, and RCT. Study selection and data extraction were independently performed by two investigators. Studies were considered eligible for inclusion if they fulfilled the following criteria: evaluated the effect of fiber diet on HbA1c and/or FPG of adults patients with type 1 or type 2 diabetes, had at least eight-weeks duration, and described mean (or differences between means) and standard deviations of outcomes at baseline and end-of-intervention. Fiber data were described as the difference between intervention and control diets. Changes in HbA1c (percentage) and FPG (absolute values) were reported as difference between arithmetic mean before and after intervention. Pooled estimates of weighted mean differences (WMD) and 95% CIs were obtained by random-effects models. The Cochran's x test was used to evaluate heterogeneity between studies and I² test to evaluate the heterogeneity magnitude. Publication bias was assessed by Begg's and Egger's tests. Statistical analyses used Stata 11.0 software.

Results: From 18,446 studies initially identified, 60 were selected for full text evaluation based on title, abstract, and reference lists. Thereafter, 12 studies (including 14 reports) with eight to 24 weeks duration (nine with parallel and three with crossover designs) fulfilled the inclusion criteria providing data from 659 diabetic patients, aged 58.2 years (28 to 69.1), 61.3% males, and 91.7% with type 2 diabetes. In five reports the intervention was diet with foods rich in fiber (fiber difference=3.0 to 22.5 g/day). In seven reports the intervention was dietary fiber supplement (fiber difference=3.5 to 16.5 g/day): goma-guar (4 reports), psyllium (2 reports), or β-glucan (1 report). HbA1c change did not differ between intervention and control diets (14 reports; WMD = -1.37% [-4.08, 1.34]; I²=80.3%, P<0.001). Pooled data about the effect of high fiber intake on FPG (9 reports) also revealed no difference as compared to control diets (WMD = -4.28 mg/dl [-15.09, 8.57]; I²=93.6%, P<0.001). These results did not change when sensitivity analyses were performed considering diets with foods rich in fiber or with fiber supplements. There was no evidence of publication bias, both for HbA1c and FPG (Funnel plots and the Egger regression test; P>0.10).

Conclusions: The present systematic review and meta-analyses did not support a beneficial effect of an increased fiber intake on glycemic control in patients with diabetes. However, studies are still necessary to evaluate this topic, since a high heterogeneity between RCTs was demonstrated.

Fibres intake is associated with lower inflammation among type 1 diabetes subjects

T.C. Rodrigues¹, C. Nascimento¹, F.R. Bernaud¹, C.H. Silva^{1,2}, B. Beck¹, M.V. Beretta¹, F. Escobar¹, G.B. Bello¹, J.C. Almeida^{3,1}, M.J. Azevedo^{1,3};

¹Endocrinology Division, Hospital de Clínicas de Porto Alegre, ²Nutrition Graduation, Federal University of Rio Grande do Sul, ³Department of Internal Medicine, Federal University of Rio Grande do Sul, Porto Alegre, Brazil.

Background and aims: Epidemiological studies have shown that vegetables intake is associated with a lower risk of cardiovascular events, possibly due to anti-inflammatory effects. In fact, lower C-reactive protein (CRP) levels were associated with high dietary intake of fruits, vegetables and grains - fiber sources foods. Patients with diabetes display a state of chronic low-grade inflammation could be related to chronic microvascular complications, and its association with insulin resistance and metabolic syndrome. In this way, the aim of this study was to evaluate an association between high-sensitivity (hs) CRP levels and composition of the usual diet of patients with type 1 diabetes

mellitus (T1DM), especially the association between the CRP-US levels and the consumption of fibers.

Materials and methods: Cross-sectional study with T1DM outpatients from the Endocrine Division of the HCPA was performed. Patients underwent clinical assessment (blood pressure levels, assessment of microvascular complications, and anthropometric measurements), nutrition (weighed diet records in two nonconsecutive week-days and one day-off, with concomitant urinary collection 24h to measurement of urinary urea) and laboratory [glycemic control, lipids, renal function (serum creatinine and microalbuminuria), and high-sensitivity CRP (hs-CRP) [immunoturbidimetric method (Siemens Advia 1800 Clinical Chemistry System, Germany)]. Patients with hs-CRP values higher than 10 mg/dl were excluded.

Results: There were 84 patients with T1DM with 41.6 ± 9.8 years old, 18 ± 9 years of diabetes duration, 50.6% male and 79.3% whites. The BMI was 24.6 ± 3.4 kg/m², waist circumference = 83.4 ± 9.3 cm, fasting glucose = 211 ± 128 mg/dl, HbA_{1c} = $9.3 \pm 2\%$, total cholesterol = 190 ± 35 mg/dl, HDL = 60.8 ± 15.8 mg/dl, triglycerides = 86 (68–118) mg/dl, urinary albumin excretion = $6.2\mu\text{g}/\text{min}$ (0.0–16), serum creatinine = 0.8 mg/dl (0.5–2.0) and values of hs-CRP = 1.67 mg/dl (0.7 to 4.71). The analysis of daily nutrient intake (% of total energy) showed carbohydrate intake = $48.9 \pm 7.8\%$, protein = $17.9 \pm 3.6\%$, total lipids = $33.3 \pm 8.6\%$, saturated fatty acids (FA) = $10.1 \pm 2.9\%$, monounsaturated FA = $11.6 \pm 3.8\%$, polyunsaturated FA = $8.1 \pm 4.8\%$, trans-FA = $0.5 \pm 0.4\%$, and cholesterol 226 ± 115 mg. Daily intake of total fiber was 23.1 ± 8.7 g. The total fiber intake was negatively correlated with the hs-CRP values: $r = 0.30$ ($P = 0.01$) and this association was supported on multiple linear regression model ($R^2 = 0.21$, $\beta = -0.58$, $P = 0.02$), adjusted for HbA_{1c}, BMI, and diastolic blood pressure (variables come from the association on univariate analysis). To facilitate understanding hs-CRP levels and fibers were stratified to each 0.5 mg/dl and portions of 5g, respectively. In an ordinal regression model, categories of hs-CRP (between 0–0.5 mg/dl; 0.51–1 mg/dl, 1–1.5 mg/dl, 1.51–2 mg/dl and ≥ 2.1 mg/dl) were included as dependent variable and the fiber intake levels, BMI and HbA_{1c} were included as independent variables. Each 5g of additional intake fiber higher than 15g/day reduced 0.5 mg/dl on hs-CRP levels.

Conclusion: The intake of at least 20g/day of fiber is associated with a reduction on hs-CRP levels in patients with T1DM.

Supported by: FIPE-HCPA

demonstrated a reduction from D-0 ($15.7 \pm 1.2\text{g}$) to D-30 ($9.1 \pm 0.5\text{g}$) ($p < 0.001$). In groups A and B there was no significant difference in FBG or 2hr post prandial BG from D-0 to D-30, in diabetes-induced animals group D demonstrated a significantly lower FBG on D-20 and D-30, and 2hr post prandial BG was also significantly lower on D-30. In CE administered groups total and LDL cholesterol levels were lower on D30 compared to D0 in healthy and diabetes-induced animals ($p < 0.001$). HbA_{1c} of group-C increased from D-0 ($2.2 \pm 0.1\%$) to D-30 ($4.5 \pm 0.9\%$) ($p < 0.001$), in group-D it remained unchanged.

Conclusion: Cinnamomum zeylanicum lowered blood glucose, reduced food intake and improved lipid parameters. Its efficacy as a standalone therapy and impact on macro and microvascular complications requires further study.

Effects of cinnamomum zeylanicum (Ceylon cinnamon) on blood glucose and lipids in Sprague-Dawley rats

P. Ranasinghe¹, Y.S. Perera², E. Abewardana³, N. Gunapala³,

S. Premakumara⁴, M. Gunatilake³, P. Katulanda¹;

¹Diabetes Research Unit, Department of Clinical Medicine, Faculty of Medicine, ²Department of Clinical Medicine, Faculty of Medicine, ³Faculty of Medicine, ⁴Industrial Technology Institute, Colombo, Sri Lanka.

Background and aims: Diabetes is a leading cause of morbidity and mortality in the world. Recent studies have demonstrated the beneficial effects of herbal remedies in its treatment. We evaluated short and long term effects of Cinnamomum zeylanicum on food consumption, body weight, glycaemic control and lipids in healthy and diabetes-induced rats

Materials and methods: The study was conducted in two phases, using Sprague-Dawley rats (body weight- $190 \pm 25\text{g}$, age 3–4 months) as the animal model. Phase-I evaluated short term effects of cinnamon on blood glucose (BG) in fasting (Group-1 and 2) and following a standard oral glucose (OG) load (Group-3 and 4), using 36 healthy rats in four equal groups. Group 1 and 3 received distilled-water (DW) and groups 2 and 4 received cinnamon-extracts (CE). Serial BG values were measured from 0–24hrs. DW/CE was administered at 0-hrs in group 1 and 2 and 0.5-hrs in group 3 and 4 (standard OG load given at 0-hrs). Phase-II evaluated long term effects of cinnamon on food consumption, body weight, BG and lipids over one month. Group-A ($n=8$, DW) and Group-B ($n=8$, CE) were healthy rats, while Group-C ($n=5$, DW) and Group-D ($n=5$, CE) were diabetes-induced rats. Serum total cholesterol, HDL cholesterol, LDL cholesterol, triglycerides and HbA_{1c} was measured on D-0 and D-30. FBG, 2 hour post-prandial BG and body weight were measured on every 5th day, together with daily food consumption.

Results: Phase I-There was no significant difference in serial BG values of groups 1 and 2. Mean percentage reduction of BG from FBG at each hour was greater in group-2 at 0.5, 1 and 2-hrs ($p > 0.05$). Group-4 demonstrated a faster decline in BG following OG load in comparison to group-3 ($p < 0.05$). Phase II-There was no difference in food consumption of healthy rats (Group-A and B) between D-0 and D-30, in diabetes-induced rats group-D

Genetically determined metabolic responses to isocaloric high carbohydrate and high saturated fat diets in healthy twins

S. Hornemann¹, M. Kruse¹, D. Hoffmann¹, A.-C. Seltmann¹, D. Stefanovski², A. Busjahn³, R.N. Bergman², A.F.H. Pfeiffer^{1,4}

¹Department of Clinical Nutrition, German Institute of Human Nutrition, Nuthetal, Germany, ²Dept. of Physiology and Biophysics, University of Southern California, Los Angeles, USA, ³Health Twist GmbH, Berlin, Germany, ⁴Dept. of Endocrinology, Diabetes and Nutrition, Charité-University Medicine, Berlin, Germany.

Background and aims: Diets high in carbohydrates and/ or fat can induce adiposity and diabetes mellitus type 2. Studies in humans showed rapid development of insulin resistance when applying a hypercaloric high fat diet. This study investigated the effects of a sudden switch from healthy low fat to isocaloric high fat diet on body weight (BW), insulin sensitivity (S_i), serum lipids and inflammatory cytokines in healthy twins.

Materials and methods: 52 monozygotic and 8 dizygotic twins (BMI 18–35 kg/m², twin BMI-difference ≤ 3 kg/m², age 18–70) were investigated for 12 weeks. An isocaloric diet rich in carbohydrates (55% carbohydrates, 15% protein, 30% fat) was applied with dietary counselling for 5 weeks and afterwards nutrients were supplied for 6 days. Then an isocaloric diet rich in saturated fat (40% carbohydrates, 15% protein, 45% fat) was applied for 6 days with nutrients supplied, followed by 4 weeks with dietary counselling and for another 6 days when nutrients were supplied again. An intravenous glucose tolerance test (IVGTT), anthropometry and blood tests for total Cholesterol, non esterified fatty acids (NEFA) and inflammatory cytokines were performed after the period of diet rich in carbohydrates (Carb), after the first 6 days (HF_{short}) and at the end of the period of diet rich in fat (HF_{long}). The IVGTT was analyzed according to the Minimal Model. Data represents the mean \pm SEM. One-way ANOVA with Bonferroni posttest was used to test the difference between the means of the groups. Pearson's correlation coefficient (PCC) was used to test the correlation of parameters within the pairs of twins.

Results: Mean BW was constant over the entire period of intervention: Carb 69.06 \pm 1.79 kg, HF_{short} 69.04 \pm 1.77 kg, HF_{long} 69.34 \pm 1.80 kg. Total cholesterol levels showed a moderate, but insignificant, increase from Carb (4.60 \pm 0.12 mmol/l) over HF_{short} (4.75 \pm 0.12 mmol/l) up to HF_{long} (4.92 \pm 0.12 mmol/l), however were always highly correlated within the pairs of twins: PCC: Carb: 0.781, HF_{short}: 0.705, HF_{long}: 0.844. Interestingly, NEFA significantly decreased at the end of the period of diet rich in fat compared to the end of the period of diet rich in carbohydrates: 0.60 \pm 0.03 mmol/l, HF_{short} 0.52 \pm 0.03 mmol/l, HF_{long} 0.49 \pm 0.03 mmol/l ($P < 0.05$ HF_{long} vs. Carb) and were only correlated within the pairs of twins after HF_{short} (PCC: 0.716). Insulin sensitivity (S_i) did not change: Carb: 13.14 \pm 1.52 [(mu/l)⁻¹.min⁻¹], HF_{short}: 15.09 \pm 3.07 [(mu/l)⁻¹.min⁻¹], HF_{long}: 12.74 \pm 1.33 [(mu/l)⁻¹.min⁻¹] and was only correlated within the pairs of twins after Carb (PCC: 0.458). MCP-1 as a marker of inflammation decreased moderately, but not significantly, over the time of intervention (Carb: 335.6 \pm 13.4 pg/ml, HF_{short}: 324.1 \pm 10.8 pg/ml, HF_{long}: 311.4 \pm 11.6 pg/ml) and was always significantly correlated within the pairs of twins: PCC: Carb: 0.491, HF_{short}: 0.702, HF_{long}: 0.607.

Conclusion: These results demonstrate the degree of genetic determination of metabolic and inflammatory responses to isocaloric dietary interventions. Supported by: BMBF

A high fat diet improves glycaemic control compared with low fat diet: a 24-month randomised prospective study of patients with type 2 diabetes in primary health care

F.H. Nystrom¹, C.J. Östgren¹, T. Lindström¹, M. Bachrach-Lindstrom¹, A.-K. Schöld², B. Dizdar¹, M. Fredrikson³, H. Guldbbrand¹

¹Medical and Health Sciences, Faculty of Health Science, Linköping University, Sweden, ²FoU Unit, County Council of Ostergötland, Linköping, Sweden, ³Clinical and Experimental Medicine, Faculty of Health Science, Linköping University, Sweden.

Background and aims: Little is known about the long-term effects of a low carbohydrate/high fat diet in type 2 diabetes. We aimed to prospectively explore the efficacy of traditional low-fat diet compared with a high-fat dietary recommendation on the metabolic profile in patients with type 2 diabetes.

Materials and methods: We randomized 61 patients (allocation 1:1) with type 2 diabetes to a low-fat diet (55–60 E% from carbohydrates, LFD) or a diet with maximal intake of 20E % from carbohydrates and 50E% from fat (HFD) in order to lose weight at two primary health care centers in Sweden. Both groups were asked to limit the total caloric intake to 1600 kcal for women/day and 1800 kcal/day for men. The patients were given dietary advises on 4 occasions in group sessions, and had access to the same dedicated dietician who also provided patients with suitable cooking recipes. The patients were followed for two years.

Results: No subjects were lost to follow up, weight loss was similar in both groups and maximal at the 6-month control (reduction at 6 months, LFD: -3.99 \pm 4.1 kg, HFD: -4.31 \pm 3.6 kg, $p=0.8$ for comparison between groups, at 12 months: LFD: -3.21 \pm 4.2 kg, HFD: -3.15 \pm 4.0 kg, $p=0.96$ between groups and at 24 months: LFD: -2.84 \pm 4.9 kg, HFD: -2.34 \pm 5.1 kg, $p=0.7$ between groups). Based on 3-day food reports, subjects randomized to HFD reduced carbohydrates and increased energy intake from fat compared with the contrasting group from baseline compared with 6 months (change in E% from fat +12.6 \pm 8.1%, from carbohydrates -17.2 \pm 8.7 E%, corresponding values for the LFD group: fat -0.93 \pm 8.4 E% from carbohydrates -0.11 \pm 8.2%, p for comparison of changes in between groups < 0.0001 for both fat and carbohydrates). While LDL-cholesterol remained unchanged in both groups at the 6 and 12 month controls, HDL cholesterol was increased at 6 months in the HFD (from 1.13 \pm 0.33 mmol/l to 1.25 \pm 0.47, $p=0.02$) and in both groups at 12 months (HFD from 1.13 \pm 0.33 mmol/l to 1.24 \pm 0.38, $p=0.02$ and in LFD from 1.09 \pm 0.29 mmol/l to 1.17 \pm 0.24, $p=0.004$). HbA1C was lowered in the HFD at the 6 month control ($p=0.004$) and tended ($p=0.12$) to be lower also at the 12 month control but not at the 24 month control ($p=0.9$). HFD baseline: 6.61 \pm 0.97%, 6-month: 6.15 \pm 1.0%, 12 month: 6.40 \pm 1.2%, 24 month: 6.62 \pm 2.7% corresponding values for the LFD group: 6.34 \pm 0.78%, 6-month: 6.25 \pm 0.93%, 12 month: 6.41 \pm 1.1%, 24 month: 6.50 \pm 1.0%. The change in HbA1C from baseline to the 6-month control was statistically significant between the groups after correction for the concomitant reduction in medication ($p=0.017$ – 0.025 depending on the correction parameters).

Conclusion: HFD can be more effective to achieve glycemic control after 6-months than LFD at similar weight loss when reduction of medication is taken into consideration. Since no adverse changes occurred regarding blood lipids by the HFD, this diet seems safe as a life style intervention to reduce the need for medication in type 2 diabetes. Furthermore, we demonstrated that improvement of glycemic control or body weight can be achieved with the input of very modest amount of resources by the health care provider, in particular if a HFD is recommended.

Impact of PUFA-omega 3 on body composition and adipocytokines levels in metabolic syndrome patients

A.D. Dragomir, G. Radulian, E. Rusu, C. Panaite, D. Cheta; University of Medicine "Carol Davila", Bucharest, Romania.

Background and aims: The aim of this study was to assess the impact of 18 months administration of ω -3 PUFA supplements on body composition and adipocytokines levels in metabolic syndrome patients.

Materials and methods: In the study were included 323 patients, 164 women and 159 men, aged 63 \pm 7.3 years, with metabolic syndrome. They were allocated to 2 groups, matched by sex, age and weight: group A - received a nutritional program consisting in diet intervention and regular physical activity; group B - received the same nutritional program + capsules of fish oil (1g eicosapentanoic acid, 1g docosahexanoic acid, 0,1g α -tocopherol acetate). Body fat mass (BFM) and body fat percent (%BF) were measured using bioimpedance analysis. Adipocytokines levels were assessed according to standard procedures. The oxidative stress was assessed using FormOX systems monitor on a blood drop. Patients were evaluated before and after the intervention.

Results: Baseline characteristics were similar between groups. After 18 months, omega-3 supplements determined a significant improvement of adipocytokines levels and body composition in group B compared with group A: leptin - 14 \pm 2.8 vs. 17 \pm 3.9; adiponectin - 12.25 \pm 3.3 vs. 9.88 \pm 2.7; leptin/adiponectin ratio - 1.14 \pm 0.84 vs. 1.72 \pm 1.44; body fat mass (BFM) - 24.82 \pm 3.4 vs. 28.67 \pm 5.5; body fat percent (BF%) - 25.92 \pm 1.6 vs. 29.64 \pm 4.8; waist-to-hip ratio - 0.98 \pm 0.06 vs. 1.06 \pm 0.05. BFM was statistically correlated with leptin values ($p < 0.0001$), adiponectin values ($p < 0.001$) and oxidative stress ($p < 0.001$), while %BF was correlated with leptin values ($p < 0.0001$), leptin to adiponectin ratio ($p < 0.0001$) and oxidative stress ($p < 0.002$).

Conclusion: Our study concluded that in metabolic syndrome patients, PUFA-omega 3 enriched diets may decrease the oxidative stress and improve adipocytokines levels and body composition.

Dietary n-3 fatty acids supplied as phospholipids are more effective than triglycerides in reducing obesity-associated disorders: evidence for a link with the endocannabinoid system

M. Rossmeisl¹, Z. Macek Jilkova¹, M.G.J. Balvers^{2,3}, K.C.M. Verhoeckx², B. Kristinsson⁴, G. Haraldsson⁴, H. Svensen⁵, V. Kus¹, P. Flachs¹, M. Bryhn⁶, J. Kopecky¹;

¹Adipose Tissue Biology, Institute of Physiology, Prague, Czech Republic, ²TNO Quality of Life, Zeist, Netherlands, ³Division of Human Nutrition, Wageningen University, Netherlands, ⁴University of Iceland, Reykjavik, Iceland, ⁵EPAX AS, Aalesund, Norway, ⁶Silentia AS, Svelvik, Norway.

Background and aims: The endocannabinoid system is a significant player in the control of energy balance and is overactive in obesity. Dietary n-3 polyunsaturated fatty acids (n-3 PUFA), such as eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), could prevent development of obesity and insulin resistance. We studied metabolic effects of n-3 PUFA in the diet either in the form of phospholipids or triglycerides.

Materials and methods: Three-month-old C57BL/6J male mice were fed for 4 months a corn oil-based high-fat diet (cHF; lipids ~35% wt/wt) to induce obesity. Mice were then randomly divided in three subgroups: 1) cHF diet supplemented with metformin (2 g/kg diet; “cHF+M” diet - control); 2) cHF+M diet, in which part of lipids was replaced by a high-DHA n-3 PUFA concentrate (EPAX 1050 TG; 60% EPA+DHA wt/wt; “E” diet); and 3) cHF+M diet, in which part of lipids was replaced by a novel marine phospholipid concentrate containing mainly DHA (G3; 27% EPA+DHA wt/wt; “G3” diet). Experimental diets were matched for the total EPA and DHA content (31.5 mg/g diet) and were administered for 9 weeks. Markers of glucose and lipid homeostasis, hepatic steatosis, adipocyte hypertrophy, and endocannabinoid levels were assessed.

Results: Both E and G3 diets tended to lower weight gain while reducing the weight of abdominal fat depot (cHF+M, 2440 ± 206; E, 1906 ± 231; G3, 1978 ± 164 mg; p=0.021 and p=0.027 for cHF+M vs. E and G3, respectively). Plasma levels of non-esterified fatty acids and total cholesterol were similarly reduced by both treatments, while G3 exerted stronger effects on plasma triacylglycerols (cHF+M, 1.09 ± 0.08; E, 0.78 ± 0.12; G3, 0.66 ± 0.04 mmol/l; p=0.016 and p<0.01 for cHF+M vs. E and G3, respectively). Only G3 reduced plasma insulin (cHF+M, 1.78 ± 0.32; E, 1.29 ± 0.30; G3, 0.91 ± 0.11 ng/ml; p=0.034 for cHF+M vs. G3) and HOMA-IR (cHF+M, 17.7 ± 3.6; E, 9.9 ± 2.0; G3, 7.3 ± 1.0; p=0.02 for cHF+M vs. G3). Furthermore, hepatic steatosis (cHF+M, 160 ± 17; E, 83 ± 15; G3, 41 ± 4 mg/g tissue; p<0.001 for cHF+M vs. G3) and adipocyte hypertrophy (cHF+M, 5961 ± 381; E, 5195 ± 349; G3, 4433 ± 127 μm²; p=0.013 for cHF+M vs. G3) were both more effectively reduced by G3. These effects were associated with reduced levels of 2-arachidonoylglycerol (2-AG; cHF+M, 187 ± 36; E, 79 ± 13; G3, 46 ± 4 ng/g tissue; p<0.001 for cHF+M vs. G3) and elevated levels of N-docosahexaenoyl ethanolamine (DHEA; cHF+M, 2.40 ± 0.15; E, 14.92 ± 1.63; G3, 31.37 ± 7.26 ng/g tissue; p<0.001 for all comparisons) in adipose tissue.

Conclusion: Compared with marine triglycerides, dietary n-3 PUFA as phospholipids ameliorated more efficiently metabolic defects such as hypertriglyceridemia, adipocyte hypertrophy, and hepatic steatosis. Possible mechanisms for this differential effect could include more efficacious reduction of endocannabinoid 2-AG and increased production of anti-inflammatory endocannabinoid-like molecule DHEA.

Effect of an alpha-linolenic enriched diet on markers of endothelial function, inflammation and glucose metabolism in patients with metabolic syndrome during weight reduction

A. Baxheinrich¹, U. Wahrburg¹, Y.H. Lee-Barkey², D. Tschöpe², B. Stratmann²;

¹Department of Nutrition Science, University of Applied Sciences, Münster, ²Heart- and Diabetes Center NRW, Ruhr University Bochum, Bad Oeynhausen, Germany.

Background and aims: The metabolic syndrome is associated with visceral obesity and closely linked to a proinflammatory state and endothelial dysfunction. Improvement of inflammation and endothelial function by marine n-3 fatty acids has been widely evaluated, whereas the effects of the plant-based n-3 fatty acid alpha-linolenic acid (ALA) are largely unknown. In a controlled dietary study, we investigated the effects of ALA on endothelial function, inflammation and glucose metabolism in patients with metabolic syndrome (MBS) during a six month weight reduction program with natural food diets.

Material and methods: 81 patients (age: 51.3±10.2 years; body weight: 98.4±18.0 kg, without intergroup difference at baseline) with diagnosed MBS according to the criteria of the International Diabetes Federation were enrolled in the study with a parallel design after stratification according to gender, age and manifestation of diabetes. During the six month dietary intervention, all patients received an energy-reduced diet which had a moderate carbohydrate (41% of energy) and fat (38% of energy) content, but a low content of saturated fatty acids (< 10% of energy). In the intervention group (IG), the diet was enriched with rapeseed oil, leading to an ALA intake of 3.6 g/d, while the control group (CG) achieved an olive oil-rich diet (ALA intake: 0.8 g/d).

Results: After six months, both groups showed a similar weight reduction (-7.8 kg in the IG vs -6.0 kg in the CG) and decline in body fat (-5.8 kg vs -4.2 kg). The concentrations of ADMA and YKL-40 significantly decreased in the IG (-5.5%; p<0.01 and -24.8%; p<0.001) but not in the CG (-4.0%, p=0.154; -12.2%, p=0.152) with intergroup differences for YKL-40 (p=0.018 for time x group), indicating an improvement in endothelial function due to ALA enrichment. The values of sE-Selectin significantly decreased in both groups (-20.7% for IG, p<0.001; -10.8% for CG, p<0.001) without significant intergroup differences (p=0.063 for time x group). The inflammatory markers hsCRP and TNF-α were also significantly reduced in the IG and CG (p<0.05 for both groups and parameters), while the change of hsIL-6 was detected in IG only (-12.8%, p<0.05) without differences between groups (p for time x group: hsTNF-α p=0.794, hsCRP p=0.279, hsIL-6 p=0.838). With regard to the glucose metabolism, we observed a slight decrease in serum glucose levels, accompanied by a significant reduction in insulin (p<0.001 for both groups) and intact proinsulin (IG p<0.001; CG p<0.05). In addition, systolic and diastolic blood pressure were reduced in both groups, but the decrease in the latter was significantly more pronounced in the IG as compared to the control group (IG -8.4 mmHg vs CG -4.4 mmHg; p=0.026 for time x group).

Conclusion: An ALA-enriched fat-moderate weight reduction diet led to a more pronounced improvement of the metabolic risk profile in patients with metabolic syndrome than did a similar diet with a low content of ALA. Especially, two recently established important markers of endothelial function, YKL-40 and ADMA, were favorably influenced by the plant-based n-3 fatty acid alpha-linolenic acid.

The effect of vegetarian diet on fatty acid composition of serum phospholipids and the association with insulin sensitivity and visceral fat in subjects with type 2 diabetes

H. Kahleova¹, M. Matoulek², L. Kazdova¹, M. Hill³, T. Pelikanova¹;

¹Diabetes Centre, Institute for Clinical and Experimental Medicine, ²1st Faculty of Medicine, Charles University, ³Institute of Endocrinology, Prague, Czech Republic.

Background and aims: Insulin sensitivity is related to the composition of fatty acids in the serum and tissue lipids. The aim of our study was to examine the effect of vegetarian vs. conventional diet on fatty acid composition of serum phospholipids and to test the relations to insulin sensitivity and visceral fat content in subjects with T2D.

Materials and methods: Subjects with T2D (n=74) were randomly assigned to the experimental group (EG, n=37) following vegetarian diet or the control

group (CG, n=37) following conventional diet. Both diets were calorie-restricted (~500 kcal/day). Participants were examined at baseline, 12 weeks of diet intervention and 24 weeks (subsequent 12 weeks of diet were combined with aerobic exercise 3 hours/week). The fatty acid composition of serum phospholipids was measured by gas liquid chromatography. Insulin sensitivity was measured by the hyperinsulinemic (1 mU.kg⁻¹.min⁻¹) isoglycemic clamp. Visceral fat was measured by magnetic resonance imaging.

Results: The linoleic acid (18:2n6) increased in EG (p=0.04) while it decreased in CG (p=0.04) in response to dietary interventions (group x time p<0.001). It did not change significantly after the addition of exercise in either group. The highly unsaturated n6 fatty acids decreased in both groups from week 0 to 24 (p<0.001 for EG; p=0.03 for CG), more in EG (group x time p=0.01), especially due to decrease of arachidonic acid (20:4 n6) in both groups (p<0.001 for EG; p=0.05 for CG), that was accordingly greater in EG (group x time p=0.01). Metabolic clearance rate of glucose (MCR) increased in both groups from week 0 to 24 (p<0.001 for each group), more in EG (group x time p=0.04). Volume of visceral fat decreased in both groups from week 0 to 24 (p<0.001 for each group), more in EG (group x time p=0.007). In EG, changes in the linoleic acid (18:2 n6) correlated positively with changes in MCR (r=+0.22; p=0.04) and negatively with changes in volume of visceral fat (r=-0.28; p=0.05).

Conclusion: Vegetarian diet increased the content of linoleic acid in serum phospholipids. Its changes were associated with changes in MCR and visceral fat. The results support the hypothesis that these changes in linoleic acid could be involved in greater capacity of calorie-restricted vegetarian diet to improve insulin sensitivity compared to conventional diabetic diet.

Effects of daidzein and genistein on glycaemic control and lipid metabolism in Chinese women with prediabetes or untreated early diabetes: a 6-mo double-blind, randomised, placebo-controlled trial

Y.-B. Ye¹, Y.-B. Li², Y.-M. Chen³, A.-L. Chen², W. Lu¹, S.-Y. Zhuo¹, J. Liu², H.-Y. Mai¹, S. Fang¹;

¹Department of Nutrition, the First Affiliated Hospital of Sun Yat-sen University, ²Department of Endocrinology, the First Affiliated hospital of Sun Yat-sen University, ³Department of Medical Statistics and Epidemiology, School of Public Health, Sun Yat-sen University, Guangzhou, China.

Background and aims: Evidence from observational, in vitro, animal and some small sample human studies have suggested that soy isoflavones have favorable effects on glucose and insulin, but intervention studies especially the purify isoflavones studies in humans are limited, and the results are controversial. We conduct this study to evaluate the effect of purify genistein and daidzein on glycemic control and lipid metabolism in adult women with impaired glucose regulation.

Methods: This randomized, double-blind, placebo-controlled study included 165 Chinese adult women age from 30 to 70 years with prediabetes or early untreated diabetes. Participants were randomly assigned to one of three arms with a daily intervention of 10 g soy protein and none (control group), 50 mg daidzein (daidzein group), and 50 mg genistein (genistein group) for 24 weeks. Blood was collected on baseline, the 12weeks, 24 weeks for the measurements of fasting glucose, HbA1C, lipids (total, HDL, and LDL cholesterol, and triglycerides) lipoprotein (a) and high sensitive C create protein (hsCRP), and glucose concentrations at 30, 60, 120, 180 minutes post 75g oral glucose load.

Results: 157 and 152 subjects completed the follow up measures at 12 and 24 weeks, respectively. Twelve weeks or 24 weeks treatment with purified 50mg genistein or 50mg daidzein did not result in any significant difference in the changes of fasting glucose and HbA1C, glucose concentrations at 30, 60, 120, 180 minutes post 75g oral glucose load, and the area under the curve of glucose among the three treatment groups (all p>0.05). There was no significant difference in the changes in total, HDL and LDL cholesterol and triglycerides, lipoprotein (a) and hsCRP, microalbuminuria and Microalbuminuria / urine creatinine in the three arms (all p>0.05), the main outcome of 24weeks treatment are display in the table.

Conclusion: Our findings suggest neither purify genistein nor daidzein has a significant effect on glycaemic control and lipid metabolism in Chinese women with prediabetes and diet-controlled type 2 diabetes.

The changes of main outcomes after treatment of 24 weeks* (mean±SD)

Mixed carotenes reduce oxidised LDL in human volunteers

R. Bradley¹, S. Max², A. Putiri¹, P. Costa-Mallen¹, M. McCrory³, A. Ceriello⁴, A. Fitzpatrick⁵, J. Probstfield⁵;

¹Bastyr University, Seattle, USA, ²Oregon Health Sciences University, Portland, USA, ³Purdue University, Laffayette, USA, ⁴University of Barcelona, Spain, ⁵University of Washington, Seattle, USA.

Background and aims: Increases in oxidized low-density lipoproteins (oxLDL) contribute to the development of atherosclerosis. A 4-armed randomized, controlled trial was performed in 60 adult participants who consumed fewer than 3.5 servings of fruits and vegetables per day in order to test the hypothesis that a mixed carotene matrix would reduce biomarkers of cardiovascular risk and post-prandial oxidative stress.

Materials and methods: We randomized participants to 28-days of supplementation with either a safflower oil placebo; small, organic vegetable-based soups and/or salads designed to be rich in pre-specified mixed carotene fractions (provided to the participants); or one of two dietary supplements containing natural, mixed carotenes. Participants presented to the Clinical Research Center in the University of Washington Medical Center at the beginning and end of the trial in order to consume a standardized control meal. Blood samples were collected to measure changes in fasting cardiovascular risk factors and post-prandial oxidized low-density lipoprotein (pp-oxLDL). Outcome measures were evaluated between groups by ANOVA and within group by two-sided, paired t-tests.

Results: Forty-seven participants completed the trial. Total carotene serum status increased significantly in two groups (P≤0.01 for each within group change; P<0.0001 by ANOVA), and select carotene fractions including alpha- and beta-carotene and lutein increased in all three active groups (P≤0.05 for within group change). Significant reductions in LDL-C were measured in the two dietary supplement groups including Group B: -8.0 mg/dl, 95% CI: -3.7 to -12.3 mg/dl, P=0.002 for change; and Group C: -8.8 mg/dl, 95% CI: -1.5 to -16.1 mg/dl, P=0.02 for change (P=0.002 by ANOVA). Change in 1-hour pp-oxLDL concentration differed significantly between groups (P=0.03 by ANOVA) and reductions were measured in fasting, 1, 2 and 4-hr pp-oxLDL in both supplement groups (P<0.05 for each).

Conclusions: The results of this clinical trial suggest a mixed, carotene matrix may impact cardiovascular risk by lowering LDL-C and pp-oxLDLs.

Pharmacokinetics, pharmacodynamics and tolerability of the glucokinase activator AZD1656, after single ascending doses in healthy subjects

M. Leonsson-Zachrisson¹, E. Norjavaara¹, M. Wollbratt¹, M. Persson¹, A.-M. Alström¹, S. Ueda², D. Röshammar¹, H. Ericsson¹;

¹AstraZeneca R&D, Mölndal, Sweden, ²AstraZeneca K.K. R&D, Osaka, Japan.

Background and aims: AZD1656 is a glucokinase activator with a postulated dual mechanism of action by activating glucokinase in the liver and pancreas and with the potential to deliver effective glucose-lowering in T2DM. Two single blind, randomized, placebo-controlled studies evaluated the pharmacokinetics and pharmacodynamics of AZD1656 in Western (SAD) and Japanese (JSAD) healthy male subjects after oral single ascending doses.

Materials and methods: To allow exploration of a wide dose range and to avoid hypoglycaemia, doses were given during a euglycaemic clamp, i.e. the subjects were kept at euglycaemic plasma levels (5.6 mM) by continuous glucose infusion. Gradually increasing single oral doses of 2 mg up to 180 mg AZD1656 suspension or placebo were administered during fasting conditions. Each subject participated once, either on AZD1656 or on placebo (3:1 in SAD and 5:1 in JSAD), with the exception of two dose groups in the SAD. Subjects in these two latter dose groups participated on 2 occasions, once on AZD1656/placebo given in fasting conditions and once on AZD1656/placebo given in combination with a standardized breakfast. Seven dose levels were evaluated in the SAD and six in the JSAD. The pharmacokinetic and pharmacodynamic variables were estimated by non compartmental and non-linear mixed effects analyses.

Results: In total, 64 healthy male volunteers from 20 to 45 years of age participated in the studies. AZD1656 was well tolerated in both populations and most adverse events were mild. No treatment related changes in ECG, vital signs or safety lab assessments were observed. Following administration of AZD1656 suspension to fasting subjects, the compound was rapidly absorbed at all dose levels studied. C_{max} was generally reached within 1 hour after intake of dose. Administration of AZD1656 with a high-fat breakfast had no effect on the AZD1656 AUC, while C_{max} was decreased and t_{max} was delayed. In both populations there was a dose-proportional increase in AUC but a somewhat less than dose proportional increase in C_{max} . AZD1656 levels were on average ~25% higher in the Japanese population. The data were best described by a two compartment model with linear elimination and saturable absorption. After scaling of disposition parameters by body weight, the pharmacokinetics were similar between the populations. An active metabolite was formed, with a longer $t_{1/2}$ than AZD1656. However, the exposure to the metabolite was only ~10% of the exposure to AZD1656. A dose-dependent blood glucose lowering effect with AZD1656, of similar magnitude across the two populations, was indirectly demonstrated through a need of increased glucose infusion rate to maintain a constant blood glucose level. Dose-dependent increases in s-insulin and c-peptide were also evident in both populations supporting the anticipated mechanism of action.

Conclusion: AZD1656 was well tolerated in single doses up to 180 mg in both populations and no safety concerns were raised. AZD1656 was rapidly absorbed, and a dose-proportional increase in exposure was observed. Taking differences in body weight into account, there was no difference in the population pharmacokinetic parameters between Western and Japanese subjects. A dose-dependent blood glucose lowering effect, of similar magnitude across the populations, was indirectly demonstrated as well as increased insulin levels.

Intact central counter-regulatory responses to hypoglycaemia induced by oral glucokinase activators in comparison with insulin infusion in healthy male volunteers

E. Norjavaara¹, H. Ericsson¹, F. Sjöberg², M. Leonsson-Zachrisson¹, L. Morrow³, M. Hompesch³;

¹AstraZeneca R&D, Mölndal, Sweden, ²Department of Clinical and Experimental Medicine, Linköping University, Linköping, Sweden, ³Profil Institute for Clinical Research, Chula Vista, USA.

Background and aims: AZD1656 and AZD 6370 are glucokinase activators (GKA) with an anticipated dual mechanism of action by activating GK in both the liver (decreased glucose output) and pancreas (increased insulin secretion). Dual mechanism GKAs may have the potential to provide efficient glycaemic control in patients with Type 2 diabetes. Because GK is also present in hypothalamic neurons, it has been hypothesized that GK activation could impair the hypothalamic hormone regulated counterregulatory response to hypoglycemia. The aims of the present studies were to assess the counterregulatory responses during a stepwise hypoglycemic glucose clamp in healthy male volunteers following a single oral dose of AZD6370 or AZD1656 in comparison to the counterregulatory response to hypoglycemia during an insulin infusion.

Materials and methods: Both studies used a randomised, open label, two-way cross-over design with at least a two week washout period between glucose clamps. Following an overnight fast, a stepwise hypoglycaemic glucose clamp with target levels of 5 mmol/L (for 60 min), 4 mmol/L (for 30 min), and 3.2 mmol/L (for 60 min) was performed. Plasma glucose was then kept at a nadir of 2.7 mmol/L for 30 min. The glucose clamp was released at 180 min, when blood glucose was allowed to increase to euglycaemia during a 60 minute recovery period. In the AZD 6370 study 12 subjects received either a single oral dose of AZD6370 (300 mg) or an insulin infusion (0.8 mU/kg/min) during the hypoglycaemic clamp. In the AZD1656 study 12 subjects received either a single oral dose of AZD1656 (80 mg) plus supporting insulin infusion or during the second clamp an insulin infusion alone (1 mU/kg/min). The counterregulatory response was assessed based on the glucagon, epinephrine, norepinephrine, growth hormone and cortisol increases.

Results: At the doses applied, only AZD6370 alone (300 mg) was able to lower plasma glucose to the hypoglycaemic target level, despite similar plasma concentrations of unbound/free AZD 6370 and AZD1656. Only by adding a supporting insulin infusion to AZD1656 could plasma glucose be lowered to achieve hypoglycaemia. There was no difference in the counterregulatory response for epinephrine, norepinephrine, growth hormone and cortisol to hypoglycaemia induced by either of the GKAs compared to insulin alone. The glucagon counterregulatory response to hypoglycaemia was blunted with both GKA compounds compared to insulin. Plasma glucagon levels (pmol/L, mean±SD) at baseline and then at a glucose level of 2.7 mmol/L were 33±6 and 32±8 with AZD6370 vs 33±5 and 49±14 with insulin, and 19±10 and 20±9 with AZD1656 vs 17±5 and 31±15 with insulin. The impaired glucagon response is likely due to intra islet hyperinsulinaemia induced by GKAs or by local GK activation of the GK receptors known to be present in the α-cells.

Conclusion: There is no alteration in the CNS hormone and sympathetic nervous system response during hypoglycaemia induced by AZD1656 or AZD6370 compared to insulin alone. However, the glucagon response was blunted, most likely due to direct effects of GKAs on the pancreas.

AZD1656, a novel glucokinase activator, lowers plasma glucose in patients with type 2 diabetes

L. Morrow¹, M. Leonsson-Zachrisson², H. Ericsson², M. Wollbratt², M. Knutsson², M. Hompesch¹, E. Norjavaara²;

¹Profil Institute for Clinical Research, Chula Vista, USA, ²AstraZeneca R&D, Mölndal, Sweden.

Background and aims: AZD1656, a novel glucokinase activator with an anticipated dual mode of action in the liver and pancreas, may have the potential to provide effective blood glucose lowering for patients with diabetes. This multiple ascending dose (MAD) study compared the safety, tolerability, pharmacokinetic (PK) properties and glucose-lowering potential of AZD1656 to placebo in patients with Type 2 Diabetes.

Materials and methods: This randomized, single-blind, placebo-controlled, two part (A & B) phase 1 study was performed in patients with Type 2 Diabetes. Pre-existing oral antidiabetic treatments were washed out one week before randomization. In part A, 32 patients (23 male, 9 female, age 53.7 yrs, BMI 30.8 kg/m²) received either 7, 20, 40 or 80mg bid of AZD1656 or placebo for 8 days. Half the dose was given the first day and, if tolerated, the full dose on the rest of the days. In part B a total of 20 patients (18 male, 2 female, age 50.2 yrs, BMI 32.1 kg/m²) started on 7.6 mg AZD1656 or placebo and over a period of 3 days were up-titrated as tolerated to 15 mg bid or a top dose of 45 mg bid and then treated for another 25 days. A follow-up visit was performed at the end of both parts.

Results: Fifty-one (51) out of 52 patients completed the study; 1 patient in part B withdrew consent. AZD1656 was well tolerated and had a good safety profile across all dose levels. The pharmacokinetics of AZD1656 were, in general, dose- and time-independent although a slightly less than dose proportional increase in C_{max} was observed. Only low amounts of AZD1656 and its equipotent metabolite were excreted in urine. Pharmacodynamic (PD) effects showed plasma glucose lowering with increasing doses of AZD1656 in part A of the study. Fasting plasma glucose (FPG) in the four dosing groups (7, 20, 40, 80 mg) decreased after 8 days by 4%, 6%, 12% and 21% compared to placebo, reaching statistical significance in the 80mg group (95% CI: -36%, -4%). FPG effects were confirmed in part B of the study with a decrease by 21% vs. placebo (95% CI: -39%, 3%). In both part A and B, mean daily (24 h) glucose levels following AZD1656 were rapidly reduced compared to placebo; in part A by up to 24% (-39%, -5%) and in part B by 28% (-46%, -3%). Serum insulin and C-peptide levels did not show any dose related changes in part A nor in part B of the study.

Conclusion: In this placebo-controlled, two part MAD study, AZD1656 was well tolerated when given as monotherapy for up to 28 days in patients with Type 2 Diabetes. At the selected doses, the PK parameters were virtually dose- and time-independent and PD effects were dose-dependent with plasma glucose lowering effects shown at all dose levels above 7 mg bid. Effects on insulin after repeated dosing were inconclusive.

Single doses of the glucagon receptor antagonist LY2409021 reduce blood glucose in healthy subjects and patients with type 2 diabetes mellitus

M.A. Deeg, E.J. Abu-Raddad, L.S. Tham, H. Fu, J.A. Pinaire, R.P. Kelly; Eli Lilly and Company, Indianapolis, USA.

Background: LY2409021 (LY) is a potent, selective antagonist of the glucagon receptor. In T2DM, glucagon levels are inappropriately elevated and contribute to hyperglycemia.

Materials and methods: This Phase 1, randomized, double-blind, placebo (PBO)-controlled, crossover study examined the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of single escalating doses of LY in healthy subjects (HS; 2.5, 10, 30, 100, 250, and 500 mg LY; N=23 males) and patients with T2DM treated with diet and exercise (T2DM; 75, 200, and 500 mg LY; N=9 [5M and 4F]); fasting blood glucose [FBG] 93.6 to 207.0 mg/dL; HbA1c 5.6 to 8.7%). In each dosing period, serial blood samples were collected for measurement of LY PK and PD and standardized meals were provided. Safety was assessed by medical exams, laboratory tests, vital signs, ECGs, and adverse events (AEs).

Results: PK parameters t_{max} , $t_{1/2}$, and apparent clearance (CL/F) were comparable across dose levels and between HS and T2DM, ranging from 4 to 8 h, 50.8 to 58.6 h, and 0.232 to 0.396 L/h, respectively. Plasma exposure of LY increased in proportion to dose in HS and T2DM. Least squares (LS) mean changes from baseline in FBG vs. PBO ranged from +2.9 to -11.5 mg/dL in HS and from -21.9 to -33.3 mg/dL in T2DM. Across LY dose groups in HS, the mean predinner (10-h post-dose) glucose value appeared 0.11 to 11.4 mg/dL lower than PBO; in T2DM, mean premeal glucose values at lunch (4-h), dinner (10-h), and breakfast (24-h), respectively, appeared from 3.6 to 42.9 mg/dL, 8.4 to 29.8 mg/dL, and 14.0 to 48.5 mg/dL lower than PBO. There were no consistent dose-related changes in postprandial glucose. In general, LY reduced fasting serum insulin, with significant LS mean changes vs. PBO ($p \leq 0.02$) observed at higher dose levels (250 and 500 mg in HS at 24-h, and 200 mg [24-h] and 500 mg [48-h] in T2DM). Notably, hypoglycemia did not occur in HS or T2DM after LY administration. There were no significant changes in laboratory tests, vital signs, or ECGs, and review of AEs indicated LY was generally well tolerated.

Conclusion: This first-in-man study demonstrated clinically significant glucose-lowering by single doses of LY in T2DM.

887

The glucagon receptor antagonist LY2409021 attenuates increases in hepatic glucose output (HGO) and blood glucose during hyperglucagonaemia in healthy male subjects

R.P. Kelly, L.S. Tham, E.J. Abu-Raddad, C.N. Lim, M.T. Loh, J.A. Pinaire, W.T. Ng;

Eli Lilly and Company, Indianapolis, USA.

Background: In type 2 diabetes, glucagon levels are inappropriately elevated, promoting HGO and contributing to hyperglycemia.

Materials and methods: This Phase 1, randomized, subject-blind, placebo (PBO)-controlled, partial crossover study examined the ability of single doses of LY2409021 (LY), a potent, selective glucagon receptor antagonist, to attenuate increases in HGO and blood glucose during hyperglucagonemia in 21 healthy male subjects (HS). Approximately 9 hr after administration of LY or PBO, an infusion of 6,6-[²H₂]glucose was started in fasted HS (5 mg/kg for 3 min, then 0.05 mg/kg/min for the next 6 h), followed 3 hr later by a simultaneous "triple infusion" (TI) of 3 h duration of somatostatin (0.1 µg/kg/min), insulin (0.07 mU/kg/min), and glucagon (6 ng/kg/min) to induce exogenous hyperglucagonemia.

Results: There were no clinically significant variations in laboratory tests or vital signs during the study, and the adverse event profile indicated LY was generally well tolerated. Before the TI, mean HGO rates and blood glucose concentrations were similar across LY dose levels: 2 to 3 mg/kg/min and 70 to 90 mg/dL, respectively. HGO and blood glucose increased approximately 2- to 3-fold during TI; however, LY attenuated increases in both the mean change from baseline in HGO (0-3 hr; normalized to pre-infusion values as shown) and the mean change from baseline in blood glucose concentration (0-3 hr) in a dose-dependent manner: by 15 to 84% and by 11 to 81%, respectively. The effects of LY on HGO and blood glucose were highly correlated ($r=0.97$; $p<0.0001$), indicating that the majority of the glucose-lowering effect of LY was due to an effect on HGO.

Conclusion: These results demonstrate the ability of LY to limit glucagon-induced increases in blood glucose, and support further examination of LY as a potential treatment for T2DM.

888

Improved glycaemic control and beta cell function by treatment with TAK-875, a GPR40 agonist, in combination with metformin in Zucker Diabetic fatty rats

K. Matsuda-Nagasumi, R. Ito, Y. Tsujihata, K. Takeuchi; Metabolic Disease Drug Discovery Unit, Pharmaceutical Research Division, Takeda Pharmaceutical Company, Ltd., Osaka, Japan.

Background and aims: GPR40 is a G protein-coupled receptor highly expressed in pancreatic β -cells that mediates free fatty acid-induced insulin secretion. TAK-875 (TAK) is a selective GPR40 agonist that lowers plasma glucose via stimulation of glucose-dependent insulin secretion. Metformin

(MET) ameliorates insulin resistance by pleiotropic action. Because of the complementary mechanisms of action, the combination of TAK and MET is expected to provide an additive improvement in glycemic control. This study evaluated acute and subchronic effects of TAK plus MET combination in Zucker Diabetic Fatty (ZDF) rats, which spontaneously develop severe diabetes and progressive β -cell dysfunction.

Materials and methods: TAK and MET were dosed by oral gavage. Acute effects of TAK (3mg/kg), MET (50mg/kg), and TAK (3mg/kg) plus MET (50mg/kg) combination treatment on postprandial glucose levels were evaluated by an oral glucose tolerance test (OGTT). In fasted ZDF rats, the acute effects of TAK (10mg/kg), MET (150mg/kg), and TAK (10mg/kg) plus MET (150mg/kg) combination treatment on fasting hyperglycemia were evaluated. Effects of subchronic treatment with TAK (3 and 10 mg/kg, BID), MET (50 mg/kg, QD) and TAK (10 mg/kg, BID) plus MET (50 mg/kg, QD) were evaluated in a 6-week multiple dosing study using ZDF rats.

Results: In an OGTT, oral administration of TAK (3mg/kg) or MET (50mg/kg) decreased glucose AUC by 21.0% or 15.4%, respectively, and TAK (3mg/kg) +MET (50mg/kg) additively decreased glucose AUC by 33.8%. In 19-week old ZDF rats with fasting hyperglycemia (ZDF: 234mg/dL; lean: 101mg/dL), combination treatment with TAK (10mg/kg) and MET (150mg/kg) additively decreased fasting plasma glucose compared with TAK or MET respectively. In a multiple dosing study, combined treatment with TAK (10mg/kg, BID) and MET (50mg/kg, QD) additively decreased glycosylated hemoglobin (TAK: -1.7; MET: -1.8; TAK+MET: -2.4%) and increased fasting plasma insulin (TAK: +7.4; MET: +8.3; TAK+MET: +13.2 ng/mL) compared with TAK or MET respectively. No significant change in fasting plasma glucagon, fasting plasma total cholesterol and fasting plasma NEFA levels were observed with any of the treatments. In addition, in TAK+MET treated ZDF rats, HOMA- β was 9.6-fold higher than control ZDF rats and pancreatic insulin content was maintained to a level comparable to normal littermates (Control: 26; TAK: 42.3; MET: 58.5; TAK+MET: 67.1; normal: 69.1 ng/mg pancreas). These results suggest that combination treatment with TAK and MET has the potential to slow the progression of diabetes and β -cell dysfunction in ZDF rats, which may result from improvements in both postprandial and fasting hyperglycemia.

Conclusion: Our results suggest that TAK plus MET combination therapy may be a valuable strategy for glycemic control and β -cell preservation in patients with type 2 diabetes.

fasting glucose from 500 to 150 mg/dL. Administration of 30 mg/kg AR-7947 significantly decreased serum triglyceride levels 37% after 14 days of dosing. Treatment with AR-7947 at low doses in combination with a DPP4 inhibitor led to 2 fold increased efficacy in an OGTT versus monotherapy.

Conclusion: These studies demonstrate that AR-7947 may show utility as a novel treatment for durable normalization of glucose and lipid profiles in patients with type 2 diabetes.

889

AR-7947, a GPR119 agonist with durable reductions in post-prandial and fasted blood glucose in preclinical models of type 2 diabetes

J.B. Fell, M. McVean, T.D. Aicher, S.A. Boyd, P. Larsen, N.A. Neitzel, L.M. Williams, S.A. Pratt, J. Fischer, R.J. Hinklin, C. Eberhardt, B. Baer, T.M. Turner, J.R. Bencsik, A.J. Celeste;
Array BioPharma Inc., Boulder, USA.

Background and aims: Agonism of the G-protein coupled receptor, GPR119, results in glucose-dependent incretin release (i.e., GLP-1) from enteroendocrine cells and insulin secretion from pancreatic β -cells. GPR119 agonists have the potential to work additively with DPP4 inhibitors leading to increased active GLP-1 levels, better glucose control and the potential for weight loss in Type II diabetic patients compared to treatment with a DPP4 inhibitor alone. Using traditional medicinal chemistry techniques, AR-7947 was identified as a selective small molecule GPR119 agonist with good physicochemical characteristics and drug-like properties. This presentation describes the *in vitro* and *in vivo* pharmacology of AR-7947.

Materials and methods: A variety of *in vitro* assays including but not limited to cellular EC₅₀, predicted metabolism, permeability, physicochemical determinations, and selectivity panels for kinases, receptors and ion channels were used to characterize AR-7947. This compound was tested *in vivo* in normal mice, rats, dogs, and monkeys to assess PK properties. Finally, C57BL/6 mice and female high fat diet fed ZDF rats were used to show proof of concept and to determine efficacy as monotherapy and in combination with a DPP4 inhibitor. GLP levels, fasting glucose, nonfasted glucose, and AUC_{glucose} in OGTT studies were monitored.

Results: *In vivo* pharmacokinetics of AR-7947 in the rat and monkey showed dose-escalating exposure, high oral bioavailability (up to 59% F) and low clearance. Studies in C57BL/6 mice demonstrated that AR-7947 increased active GLP-1 alone (4 fold) and in combination with a DPP4 inhibitor (12 fold) compared to control. In 14-day studies using female ZDF rats fed a high-fat diet, AR-7947 at 30 mg/kg significantly reduced the glucose excursion in an OGTT 49%. This treatment normalized fasting glucose and lowered non-

Effects of aleglitazar, a dual PPAR- α/γ agonist, on lipid parameters in patients with type 2 diabetes: post hoc sub-analysis comparing patients with or without statins at baseline

C. Chognot¹, R.R. Henry², M. Rabbia³, S. Meyer-Reigner¹, M. Herz¹;

¹F. Hoffmann-La Roche AG, Basel, Switzerland, ²University of California San Diego, USA, ³Hoffmann-La Roche Inc., Nutley, USA.

Background and aims: Many patients with type 2 diabetes (T2DM) also receive treatment for dyslipidemia, such as statins, to help reduce cardiovascular risk factors. However, despite the effects of statin therapy, there remains a substantial residual risk of cardiovascular events. Aleglitazar (ALE; a dual peroxisome proliferator-activated receptor [PPAR]- α/γ agonist) significantly improves glycemic and lipid parameters in patients with T2DM. In SYNCHRONY (N = 332), ALE 150 $\mu\text{g/day}$ (the dose selected for Phase III investigation; n = 55) increased high-density lipoprotein cholesterol (HDL-C) by 21% and decreased triglycerides and low-density lipoprotein cholesterol (LDL-C) by 43% and 15%, respectively from baseline compared with placebo (n = 55), with no adverse cardiovascular effects. ALE 150 $\mu\text{g/day}$ increased apolipoprotein A1 levels and decreased levels of apolipoprotein B compared with placebo. Improvements in all parameters with ALE were numerically greater than with pioglitazone (PIO). Fibrinogen was decreased with ALE and increased with PIO. The post hoc sub-analysis of SYNCHRONY presented here investigated the effects of ALE 150 $\mu\text{g/day}$ on lipids in patients receiving statins at baseline (15% of study population) compared with statin-free patients.

Materials and methods: Least squares mean changes in lipoproteins from baseline to study end in statin-treated versus statin-free patients were assessed using ANCOVA (treatment as fixed effect; baseline value as covariate) in patients randomized to 16 weeks' double-blind treatment with ALE 150 $\mu\text{g/day}$ or placebo, or to open-label PIO 45 mg/day.

Results: ALE treatment reduced LDL-C (-19.80% and -7.29%) and triglycerides (-32.91% and -25.68%) and increased HDL-C (26.15% and 23.30%) in both statin-treated and statin-free groups, respectively (Table), with improvements numerically greater in statin-treated patients. Conversely, PIO increased LDL-C in both statin-treated and statin-free patients.

Conclusion: Despite low patient numbers, these results suggest that ALE may have beneficial effects on lipid parameters in patients with T2DM in addition to those provided by statin therapy.

LIM-0705: A novel small molecule insulin sensitizer which improves glycemic control in rodent models of insulin resistance/type 2 diabetes and glucose tolerance in healthy volunteers

M.P. Chang¹, M.Z. Chen², M.D. Lee¹, V.J. Lee¹, R.J. Simon¹, J.M. Olefsky², W.R. Robbins¹;

¹Limerick BioPharma, South San Francisco, ²Department of Medicine, University of California, San Diego, USA.

Background and aims: Type II diabetes is characterized by peripheral insulin resistance and insulin deficiency. Thiazolidinedione (TZD) drugs, including rosiglitazone, exhibit potent antidiabetic and insulin sensitizing effects but are associated with adverse effects including weight gain and edema. Therefore, insulin sensitizers working through complementary mechanisms are urgently needed. LIM-0705 is a novel insulin sensitizer under development for the treatment of metabolic diseases. In this study, the pharmacological effects of LIM-0705 were examined in vitro, in the Zucker diabetic fatty (ZDF) rat model, in the diet induced obesity (DIO) mouse model and in normal human volunteers.

Materials and methods: The effect of LIM-0705 on glucose production and AMPK activation was evaluated using H4IIE cells (rat hepatoma). Agonist activity against 12 human nuclear hormone receptors including PPAR α , β , δ , γ was evaluated in reporter gene assays. The effects of 42 day i.p. LIM-0705 treatment (114 mg/kg) or rosiglitazone (6 mg/kg) on plasma glucose and lipid metabolism were evaluated in obese ZDF rats (7 wk, 269 g). The effects of 6-8 week i.p. LIM-0705 treatment (100 mg/kg) on glucose regulation and insulin sensitivity was examined in DIO mice (C57BL/6 mice, 18 wk, 47 g) by hyperinsulinemic-euglycemic and hyperglycemic clamp studies. LIM-0705 was studied in a Phase I study with 11 healthy male volunteers (750 mg, BID, p.o.) for 14 days. Metabolic assessments were made for glucose and lipid/cholesterol regulation and by OGTT.

Results: LIM-0705 inhibited glucose production in H4IIE cells (IC_{50} = 6-12 μM) with no cytotoxicity and did not activate AMPK. LIM-0705 showed no agonist activity (<4 fold @ 10 μM) against all 12 nuclear hormone receptors tested. Treatment of ZDF rats with LIM-0705 for 42 days caused rapid and significant reductions in basal glucose levels (501, 207 and 134 mg/dL for vehicle, LIM-0705 and rosiglitazone, respectively, $p < 0.0002$ for both groups compared to vehicle). Day 42 HbA1c levels were significantly reduced (6.1%, 3.3%, and 3.1% for vehicle, LIM-0705 and rosiglitazone, respectively, $p = 0.006$). Rosiglitazone treated rats had a 48% increase in weight compared to vehicle ($p = 0.0007$) while LIM-0705 rats had a 9% ($p = 0.13$) increase. Improvements in basal glucose levels were observed in DIO mice treated with LIM-0705 for 6-8 weeks (-18%, $p = 0.005$), without significant weight gain. Furthermore, under hyperinsulinemic-euglycemic clamp conditions, the glucose infusion (GIR) and insulin stimulated glucose disposal rates (IS-GDR) increased (38.5%, 27.5%, GIR and IS-GDR respectively, $p < 0.03$). In healthy male volunteers who received LIM-0705, 2-hour OGTT glucose values were significantly improved (-12.4% on Day 8, $p = 0.0006$ and -17.1% on Day 14, $p = 0.03$).

Conclusion: LIM-0705 is a novel insulin sensitizer that inhibits glucose production in hepatocytes through a pathway distinct from TZDs and metformin. LIM-0705 treatment produces anti-glycemic effects comparable to rosiglitazone in ZDF rats, improves GIR and IS-GDR under clamp conditions in the DIO mouse, and improves 2-hour OGTT in human volunteers. Chronic dosing of LIM-0705 did not cause significant weight changes compared to vehicle. Further development in insulin resistant and metabolic disease patient populations is warranted.

The effect of KB003305, a liver selective glucocorticoid receptor antagonist, on fasting plasma glucose and oral glucose tolerance after multiple oral doses in patients with diabetes type 2

T. Jax^{1,2}, C. Kapitza¹, S. Nilsson³, O. Breuer³;

¹Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany,

²University of Witten/Herdecke, Witten, Germany, ³Karo Bio AB, Huddinge, Sweden.

Background and aims: In the fasting state, hepatic glucose output (HGO) is the major glucose source. One of the key hormones that promote HGO is cortisol. KB003305 is a novel, first-in-class anti-diabetic agent for the treatment of type 2 diabetes through liver-targeted antagonism at the glucocorticoid receptor. KB003305 has shown high affinity to the glucocorticoid receptor in

vitro and potent anti-diabetic activity in animal models of diabetes. The aim was to investigate the safety, tolerability, pharmacokinetics and pharmacodynamics of repeated oral doses of KB003305 as monotherapy in patients with type 2 diabetes mellitus.

Materials and methods: The design was a randomised, double-blind, placebo controlled, multiple-dose administration, of 100 mg three times daily for 7 days followed by another 7 days of 150 mg 3 times daily. A total of 21 subjects were treated, 14 subjects on active substance and 7 on placebo. Safety variables, pharmacokinetics as well as pharmacodynamic parameters were assessed at baseline (day -2), and after one and two weeks of treatment. Daily fasting plasma glucose (FPG) was measured.

Results: Within-group statistical analysis showed that on treatment with KB003305, FPG was significantly lower than baseline from treatment day 3 and onwards. Placebo treatment FPG levels were higher on all days compared to baseline, but this was statistically significant only for treatment days 5, 13, 14, and 15. Between-group analysis demonstrated significantly lower FPG levels with KB003305 treatment as compared to placebo from treatment day 3 and onwards. Thus, FPG levels were, in comparison to placebo, lowered by 18% on treatment day 7 and by 28% (one-sided 95% CI [$-\infty$, 21%]) on day 14. KB003305 was well tolerated; minor gastrointestinal adverse events occurred mostly during the first treatment days and tended to diminish over time.

Conclusion: KB003305 is a promising new first-in-class anti-diabetic compound with liver-targeted glucocorticoid receptor antagonism which suppresses hepatic glucose production and thus improves fasting plasma glucose without apparent systemic side effects in type 2 diabetic patients.

Time-action profile of oral enteric insulin in comparison to NPH insulin in Chinese healthy volunteers

J. Li;

Endocrinology and Metabolism, West China Hospital, West China Medical School, Sichuan University, Chengdu, China.

Background and aims: Oral administration of insulin has the potential advantage of a more physiological action by its direct effect on hepatic glucose production. In this study, bio-adhesive calcium phosphate embedded insulin nano-particles with enteric coated capsules were used to facilitate gastrointestinal insulin absorption and overcome gastric acid damage. The aim of the study was to evaluate the pharmacodynamic profiles and duration of action for three oral doses of insulin (50,100 and 200 IU) and one subcutaneous dose of NPH insulin (6 IU).

Materials and methods: This single-center, randomized, four-period, cross-over study was carried out under euglycemic clamp conditions in 12 healthy volunteers. Serum insulin concentrations and glucose infusion rates (GIRs) to keep blood glucose concentrations constantly at 5.0mmol/L were monitored over 12 hours. A low dose infusion of regular insulin (0.15mIU/kg/min) was applied for the entire duration of this euglycemic clamp study to suppress endogenous insulin secretion.

Results: Administration of either NPH or enteric insulin capsules (50,100 and 200IU) increased GIRs. The time for reaching a maximum value of enteric insulin capsules was 250 ± 118 min, 170 ± 58 min, 236 ± 132 min, respectively, versus 243 ± 79 min for NPH. Onset of action (T_{effect}) was longer with capsules of 50IU (38 ± 10 min), 100IU (41 ± 18 min), 200IU (65 ± 58 min) versus NPH (35 ± 8 min). The maximal metabolic activity (GIR_{max}) observed of enteric insulin capsules was lower compared with NPH (GIR_{max} 1.66 ± 0.50 , 1.61 ± 1.00 , 1.80 ± 0.60 , respectively, vs. 2.06 ± 0.82 mg/kg/min). A pronounced peak as same as NPH with enteric insulin capsules was detected in the first 1 hour after administration. The metabolic effect measured over 10 hours tended to be lower with enteric insulin capsules compared with NPH insulin (GIR-AUC₀₋₆₀₀ min 428 ± 269 , 457 ± 254 , 421 ± 332 , vs. 658 ± 405 mg/kg). The relative effectiveness of enteric insulin capsules was 37.0 ± 90.0 , 13.0 ± 27.2 , 11.0 ± 28.8 respectively, vs. 100.0 ± 0.0 of NPH insulin. No dose-response relationship in the absorption and metabolic effect of the enteric insulin capsules was observed among 50IU, 100IU, and 200IU capsules.

Conclusion: Comparison of the pharmacodynamic and pharmacokinetics summary parameters of enteric insulin capsules obtained with Chinese volunteers to NPH insulin, we conclude that: (a) Oral enteric insulin capsules showed a similar time-action profile as NPH insulin. (b) Administration of oral enteric insulin demonstrated an obvious hypoglycemic effect with only a small increase in circulating plasma insulin concentrations. These characteristics discussed above suggest that the possible metabolism of oral enteric

insulin capsule as same as the natural insulin production is limited to the liver with a lower risk of hypoglycemia.

Inhibition of the CCR2 chemokine receptor in diabetic mice results in a rapid and robust improvement of hyperglycaemia

J.C. Jaen, Z. Miao, N. Zhao, R. Berahovich, L. Ertl, T. Baumgart, A. Krasinski, K. Greenman, P. Bekker, J. Powers, T.J. Schall, T. Sullivan; Biology, ChemoCentryx, Inc., Mountain View, USA.

Background and aims: The role of inflammation in diabetes continues to be elucidated, especially the impact that infiltrating monocytes can have on multiple tissues involved in the disease. Increased adiposity leads to recruitment of inflammatory myeloid cells into adipose tissue and production of factors known to impair systemic insulin sensitivity (i.e., TNF α , IL-6, and MCP-1). Also, myeloid cell recruitment into diabetic liver has been associated with alterations in key metabolic pathways. The current studies were undertaken to address the mechanism by which interventional CCR2 antagonism improves glycemic control in diabetic mice.

Materials and methods: CCX417 (a small molecule CCR2 antagonist, analogue of the clinical compound CCX140-B, which recently completed a Phase 2 clinical trial in type 2 diabetics) was dosed daily to male db/db mice (age 12-19 weeks) for up to 3 weeks. Weekly assessments included body weights, fasting plasma glucose, 24-hr urinary volume and urinary glucose output, and terminal measures included hepatic triglyceride and glycogen content, and hepatic activity of glucose-6-phosphatase (G6Pase) and phosphoenolpyruvate carboxykinase (PEPCK).

Results: Treatment with CCX417 for 2 weeks significantly improved glycemic control in both models of type 2 diabetes. CCX417 significantly reduced fasting plasma glucose levels in db/db mice (250 mg/dL vs. 350 mg/dL; $p=0.05$ after 1 week; 300 mg/dL vs. 470 mg/dL; $p=0.03$ after 2 weeks). Treated db/db mice also displayed significant reductions in urinary volume (3.5 mL/day vs. 9.0 mL/day; $p=0.002$) as well as glucosuria after 2 weeks (1000 mg/day vs. 1500 mg/day; $p=0.05$). Systemic lowering of glucose levels coincided with a reduction in hepatic G6Pase activity after 2 weeks (12 μ mol/min/g vs. 18 μ mol/min/g; $p=0.001$). Improved glycemic control also coincided with reductions in hepatic triglyceride levels (2.2 mg/g vs. 4.3 mg/g; $p=0.02$).

Conclusion: Robust and rapid improvements of hyperglycemia and glucosuria were seen following pharmacological intervention with a small-molecule CCR2 antagonist in a mouse model of type 2 diabetes. These results support the continued clinical evaluation of CCR2 antagonists, such as CCX140-B, for the treatment of type 2 diabetes and diabetic co-morbidities such as hepatic steatosis.

CCR2 Antagonist Effect in Diabetic db/db Mice After 2 Weeks of Treatment

	Vehicle Treated Mice	CCR2 Antagonist Treated Mice	p-value
Fasting Blood Glucose (mg/dL)	470	300	0.03
Urinary Volume (mL/day)	9.0	3.5	0.002
Urinary Glucose (mg/day)	1,500	1,000	0.05
Hepatic G6Pase Activity (μ mol/min/g)	18	12	0.001
Hepatic Triglycerides (mg/g)	4.3	2.2	0.02

895

Safety and efficacy of monthly s.c. canakinumab administration for the treatment of hyperglycaemia in metformin monotherapy-treated type 2 diabetic patients

J. Hensen¹, C. Howard², K. Frusciante², T. Thuren²;

¹Klinikum Hannover Nordstadt, Germany, ²Novartis Pharmaceuticals Corporation, East Hanover, USA.

Background and aims: Canakinumab is a human monoclonal anti-human IL-1 β antibody of the IgG1/k isotype that binds to human IL-1 β and thus blocks the interaction of this cytokine with its receptors. This action potentially reduces inflammation thereby preserving/improving β -cell function. The purpose of this study was to determine the optimal dose of canakinumab when dosed once a month s.c. to improve blood glucose control in metformin-treated patients with type 2 diabetes mellitus.

Materials and methods: The primary objectives were to assess the effect on HbA_{1c}, and the safety and tolerability of four doses of canakinumab (5 mg, 15 mg, 50 mg, and 150 mg) vs. placebo as an add-on regimen to metformin over 4 months. Total enrollment in the study included 551 patients (canakinumab=372, placebo=179) with a mean age: 54.1 years (range=28–74 years), 56.4% male, a mean weight (SD) of 81.1 (20.05) kg, a mean BMI of 29.8 kg/m², and a mean HbA_{1c} at baseline of 7.4%.

Results: Modest improvement in HbA_{1c}, at each dose of canakinumab with maximum benefit at the 50-mg monthly dose, is shown in the table. Table: Between-treatment analysis (ANCOVA) of the least squares mean change from baseline in the HbA_{1c} (%) at month 4

	Canakinumab 5 mg	Canakinumab 15 mg	Canakinumab 50 mg	Canakinumab 150 mg	Placebo
Change from baseline	-0.20	-0.29	-0.31	-0.25	-0.13
Placebo- adjusted change from baseline	-0.06	-0.16	-0.18	-0.12	

Safety results showed that canakinumab treatment was safe and well tolerated. The most common adverse events were nasopharyngitis, urinary tract infections, and upper respiratory tract infections. There were no significant differences in adverse events between the canakinumab and placebo groups.

Conclusion: Canakinumab lowered HbA_{1c} modestly, approximately -0.20% (placebo adjusted) from a baseline of ≈7.4%. This confirms that blocking IL-1 β -mediated inflammation by canakinumab results in small improvements in glycemic control, potentially improving β -cell function. There was no dose response detected between active canakinumab doses, but all doses lowered HbA_{1c} between -0.20% to -0.31% (-0.06% to -0.18% in placebo-adjusted analysis). No new safety signals were seen in this study. The safety and tolerability profile is consistent with the known safety experience of canakinumab in other trials.

896

IL-1 β antibody (canakinumab) improves insulin secretion rates in subjects with impaired glucose tolerance and type 2 diabetes treated with differing diabetes therapies

A. Rissanen¹, C. Howard², J. Botha³, T. Thuren²,

¹Biomedicum, Helsinki, Finland, ²Novartis Pharmaceuticals Corporation, East Hanover, USA, ³Novartis Pharmaceuticals Corporation, Basel, Switzerland.

Background and aims: Canakinumab is a human monoclonal anti-human IL-1 β antibody of the IgG1/k isotype that binds to human IL-1 β and thus blocks the interaction of this cytokine with its receptors, thereby neutralizing the activity of IL-1 β . IL-1 β -mediated inflammation has been implicated in suppression of insulin secretion and worsening β -cell function in patients with diabetes. The primary objective of this trial was to evaluate canakinumab effects on change from baseline of meal challenge-derived insulin secretion rate (ISR) relative to glucose.

Materials and methods: Subjects were enrolled in the following type 2 diabetes mellitus (T2DM) populations: 1) on stable metformin monotherapy, 2) on a stable metformin dose in combination with a sulfonylurea (SU), 3) on metformin in combination with an SU and a thiazolidinedione (TZD), 4) on at least two insulin injections a day with or without metformin, and subjects with impaired glucose tolerance (IGT). Subjects received a single dose of 150 mg canakinumab s.c. at week 0 and underwent a standard meal challenge test at weeks 0 and 4. Subjects were randomized either to canakinumab 150 mg s.c. or placebo in a 2:1 ratio except for IGT subjects who were randomized 1:1.

Results: Randomized set: 246 subjects were analyzed (canakinumab=154, placebo=92). There were 126 subjects with T2DM and 28 subjects with IGT treated with canakinumab, and 65 subjects with T2DM and 27 subjects with IGT who received placebo. The mean age of all subjects was 57.4 years (54% male), the mean baseline HbA_{1c} for subjects with T2DM was 7.1% and the mean HbA_{1c} for subjects with IGT was 6.1%. The mean duration of T2DM was 9.4 years. The results of the change in ISR relative to glucose at week 4 from baseline are shown in the table.

Treatment arm	Canakinumab minus placebo (0 to 30 min) pmol/min/m ² /mmol/L	Canakinumab minus placebo (0 to 60 min) pmol/min/m ² /mmol/L	Canakinumab minus placebo (0 to 2 h) pmol/min/m ² /mmol/L*	P Value
Metformin alone	-1.40	0.42	0.17	
Metformin + SU	-0.18	-0.11	-0.41	
Metformin + SU +TZD	-0.43	-1.29	-1.95	
Insulin 2/day \pm Metformin	3.81†	2.70	1.72	†p=0.0525
IGT	3.92‡	2.54	0.43	‡p=0.1729

*Primary endpoint.

Modest increase in ISR relative to glucose (0–30 min) reflecting first-phase insulin secretion was observed in insulin-treated T2DM and in IGT groups. Other groups did not show consistent effects on ISR relative to glucose. There were no deaths or serious adverse events (AEs) in this single-dose study. The most frequently reported AEs (at least 2 subjects in any treatment group) were tremor (6 subjects, 2.5%), hyperhidrosis (5 subjects, 2.0%), dizziness (4 subjects, 1.6%), hypoglycemia (4 subjects, 1.6%) and nasopharyngitis (3 subjects, 1.2%). The safety assessment of canakinumab in this study is consistent with the favorable safety and tolerability seen in other trials.

Conclusion: In conclusion, insulin-treated subjects, whether using metformin or not, as well as IGT subjects, had a trend toward improving ISR relative to glucose (0–30 min) when treated with canakinumab. This result supports the hypothesis that blocking IL-1 β in pancreatic islets has the potential to improve β -cell function by reducing suppression of insulin secretion by IL-1 β -mediated inflammation in these subgroups.

Clinical Trial Registration Number: NCT01068860

Pharmacokinetic (PK) and pharmacodynamic (PD) modelling of subcutaneous (SC) LY2189102, a neutralising IL-1 β antibody, in patients with type 2 diabetes mellitus

E. Abu-Raddad¹, A. DeGaetano², S. Bihorel³, J. Fiedler-Kelly³, J. Sloan-Lancaster¹,

¹Chorus, Eli Lilly and Company, Indianapolis, USA, ²Istituto di Analisi dei Sistemi ed Informatica “A. Ruberti”, Consiglio Nazionale delle Ricerche, Rome, Italy, ³Cognigen Corporation, Buffalo, USA.

Background and aims: LY2189102, a humanized neutralizing IL-1 β antibody, was studied in type 2 diabetes mellitus (T2DM) patients with C-reactive protein (CRP) \geq 2 mg/L, who received weekly subcutaneous doses of LY2189102 (0.6, 18 or 180 mg) or placebo over 12 weeks, and were monitored for 12 additional weeks. This report describes the selection of dose level and frequency of LY2189102 treatment using modeling and simulation of LY2189102 PK/PD relationships.

Materials and methods: Data from 106 patients were used in this analysis. A 2-compartment mammillary model with dose-dependent first-order input and bioavailability was fitted to pooled PK data from this study and a previous study conducted in rheumatoid arthritis patients receiving LY2189102 intravenously. Bioavailability (F) was coded as $F = 1 / (1 + \exp(-(F_A + F_S / \text{Dose})))$, and the absorption half-life (T_{ka}) was coded as $T_{ka} = \alpha \cdot F$, where F_A , F_S , and α were estimated parameters, and Dose is in mg. Concentrations predicted using the individual Bayesian estimates of PK parameters were used as a forcing function in the PK/PD model, which simultaneously fitted fasting glycemia, insulinemia and HbA_{1c} data. In this model, glucose-dependent insulin secretion capacity (ISC) had a zero-order input and LY2189102-concentration-dependent (inhibitory E_{max}) first-order output. Glycemia and insulinemia were interdependently related through ISC and fixed insulin sensitivity and liver glucose output parameters. HbA_{1c} was governed by an input rate that is dependent on glycemia and unglycated hemoglobin, and a first order output. Simulations of a wide range of doses and administration frequencies, from once weekly to once every 6 weeks, were conducted.

Results: Data from 5 patients whose PK profiles indicated presumed development of immunogenicity were excluded. The total clearance (CL), distributional clearance (Q), central volume (V_c), peripheral volume (V_p), F_A , F_S and α were (estimate (%SEM)) 9.45 (4.4%) mL/h, 25.1 (16%) mL/h, 3.06 (7.7%) L, 1.91 (7.7%) L, -0.42 (25%), 0.837 (21.1%) and 217 (10.9%) h, respectively. Inter-individual variability in CL, V_c, V_p and T_{ka} was 44.2%, 51.9%, 69.2%, and 57.9%, respectively. Placebo effect, LY2189102's maximum inhibition of insu-

lin secretion output (I_{\max}), the concentration at 50% effect (IC₅₀), and insulin secretion loss rate constant were 6.5% (45%), 10.4% (39%), 342 $\mu\text{g/L}$ (277%), and 4.72 mo^{-1} (37%), respectively. Inter-subject variability in PD parameters was modest. Simulation, conditional on final estimates, showed that while total administered doses saturably determined the magnitude of response, all studied administration schedules were essentially equivalent, probably due to the long half-life of the compound. A dose of 60 mg, administered once every 6 weeks, sustains near maximum glycemic response (-0.9 mM from baseline, -0.55 mM from placebo), while an 18 mg dose sustains 75% of the maximal response. Glycemic response plateaus by 3 months, while the HbA_{1c} response at 6 months was 14% higher than that at 3 months.

Conclusion: Dosing (SC) of LY2189102 can be as infrequent as once every 6 weeks, potentially offering a convenient therapeutic alternative for patients with T2DM.

Clinical Trial Registration Number: NCT00942188

898

Safety, tolerability and efficacy of subcutaneous (SC) LY2189102, a neutralising IL-1 β antibody, in patients (Pts) with type 2 diabetes

J. Sloan-Lancaster¹, E. Abu-Raddad¹, J. Polzer¹, J.W. Miller¹, J.C. Scherer¹, J.K. Berg², W.H. Landschulz¹;

¹Chorus, Eli Lilly and Company, Indianapolis, ²Cetero Research, San Antonio, USA.

Background and aims: Inflammation is associated with pancreatic beta cell apoptosis and reduced insulin sensitivity. Literature suggests IL-1 β could be a primary contributor to type 2 diabetes (T2DM). This study aimed to determine the efficacy, safety, and tolerability of LY2189102, a humanized neutralizing IL-1 β antibody, in T2DM Pts.

Materials and methods: This was a randomized, double-blind, placebo (pbo) controlled, parallel design study which enrolled 106 Pts with T2DM on diet and exercise, with or without anti-diabetic medication (excluding thiazolidinediones [TZD] and insulin). Pts equally randomized to LY (0.6, 18, 180 mg) or pbo received weekly SC doses for 12 weeks (wks; 13 total doses) with an additional 12 wks follow-up. The primary objective was the change from baseline (CFB) in HbA_{1c} after 12 wks of dosing for the compliant set (≥ 11 doses). Sample size based on 1-sided 75% confidence interval (CI) in CFB between LY and pbo being $\leq -0.68\%$ HbA_{1c}.

Results: All 3 LY2189102 dose groups showed significant (based on 75% 1-sided CI) reduction in HbA_{1c} at 12 wks compared to pbo (Table). Numerical reduction in HbA_{1c} remained evident at the end of 24 wks compared to pbo. There was no obvious dose-response relationship. Fasting glucose CFB was significantly reduced compared to pbo at multiple timepoints and numerical estimates increased closer to baseline at 24 wks. No significant differences were seen in response among predefined ligand and receptor genotypic variants. A significant ($p < 0.05$) and early anti-inflammatory effect was demonstrated, best reflected by C-reactive protein (CRP) response, and appeared saturated and sustained at end of follow-up. Both IL-6 and PAI-1 showed a dose-related numerical reduction. LY2189102 was well tolerated with 4 treatment emergent (TE) serious adverse events (SAEs) in 2 Pts (0.6mg, 18mg), none considered to be drug-related. Five Pts (3 at 18mg, 2 at 180mg) were discontinued due to TEAEs. A similar percentage of Pts reported at least 1 TEAE across all treatment groups. The incidence of TEAEs associated with Infections and Infestations across treatment groups was 34.6%, 23.1%, 22.2% and 18.5% for 0.6, 18, 180 mg and pbo, respectively.

Conclusion: LY2189102 given SC weekly for 12 wks was well tolerated, modestly reduced HbA_{1c} and blood glucose, and demonstrated significant anti-inflammatory effects in T2DM Pts. Neutralizing IL-1 β holds promise as an adjuvant treatment for T2DM.

PS 077 From IGT to type 2 diabetes: pathways and prevention

899

Risk factors of conversion from IGT and IGF to diabetes type 2 middle-aged population

A. Gilis-Januszewska, B. Piwonska-Solska, K. Szafraniec, D. Pach, A. Hubalewska-Dydejczyk;
Collegium Medicum Jagiellonian University, Krakow, Poland.

Background and aims: To determine the predictive risk factors for the development of type 2 diabetes mellitus (DM) in patients with impaired glucose tolerance (IGT) or impaired fasting glucose (IFG) during the 8,5 follow up.

Materials and methods: This is an eight year prospective study in a randomly selected urban population including 2838 subjects aged ≥ 40 years living in Krakow. 706 had IGT (387) or IFG (319) based on WHO criteria and 264 of them attended the follow-up assessment eight years later. Subjects underwent a physical examination including weight/height, waist circumference, biochemical examination including glucose, insulin in 0', 120' OGTT and questionnaire examination concerning CVD health history and family history of type 2 diabetes.

Results: The prevalence of type 2 diabetes in examined population of 264 people with previously (1998-2000) found IGT or IFG was 17%. Diabetes type 2 was found in 22% of people with previously diagnosed IFG and in 13 % of people with previously found IGT. Among people with diagnosed diabetes, 51% had newly diagnosed diabetes during the control study, in 49 % participants diabetes was diagnosed before in the period between the baseline and control study. In the studied population statistically significant predictive factors of the progression to type 2 diabetes were fasting glycemia (RR 3,27; $p < 0,001$), fasting hiperinsulinemia (RR 2,1; $p < 0,05$), insulin resistance measured as HOMA IR index (RR 1,99; $p < 0,05$), WHR, (RR 1,67, $p < 0,01$) and family history of type 2 diabetes (RR 2,21; $p = 0,01$).

Conclusion: In the studied population important predictive factors of the progression to type 2 diabetes were fasting glycemia, fasting hiperinsulinemia, insulin resistance measured as HOMA IR index, WHR, and family history of type 2 diabetes.

Risk of diabetes			
baseline	RR	95% CI	p
BMI	1,04	0,97-1,10	ns

Potential impact of elevated HbA_{1c} and impaired fasting glucose on population for predicting risk of diabetes: the Toranomon Hospital Health Management Center Study

Y. Heianza^{1,2}, S. Hara², C. Horikawa¹, K. Saito^{1,2}, A. Sugawara¹, K. Fujiwara¹, S. Kodama^{1,2}, S.D. Hsieh², H. Tsuji², H. Shimano¹, N. Yamada¹, Y. Arase², H. Sone^{1,2};

¹Department of Endocrinology and Metabolism, University of Tsukuba Mito Medical Center, ²Health Management Center, Toranomon Hospital, Tokyo, Japan.

Background and aims: Although evidence has suggested that individuals with both impaired fasting glucose (IFG) and elevated HbA_{1c} have a markedly increased risk of diabetes, the potential impact of these factors among the total population, including the effects of the markedly increased risk and the prevalence of individuals classified as having pre-diabetes, has not been clarified. We therefore tested the hypothesis that, although the number of pre-diabetic individuals identified by both IFG and elevated HbA_{1c} criteria may be small, the markedly increased risk effectively contributes to the prediction of future diabetes, in a large cohort of Japanese individuals.

Material and methods: The study enrolled 4670 men and 1571 women aged 24-82 years without diabetes (diabetes: fasting plasma glucose (FPG) ≥ 126 mg/dl, HbA_{1c} $\geq 6.5\%$, or self-reported clinician-diagnosis diabetes). Baseline diagnosis of pre-diabetes was made according to IFG (FPG 100-125 mg/dl, IFG100; or FPG 110-125 mg/dl, IFG110) or elevated HbA_{1c} (5.7-6.4%, HbA_{1c}5.7; or 6.0-6.4%, HbA_{1c}6.0). We used a combination of two tests with alternative cut-offs for diagnosing pre-diabetes. The potential impact on the study population, including the effects of risk and prevalence, was evaluated by population attribute risk percent (PAR%). The follow-up duration was a median of 5.0 years on an annual basis, during which 338 incident cases of diabetes occurred.

Results: PAR% was 68% for IFG100, 44% for IFG110, 50% for HbA_{1c}5.7%, and 31% for HbA_{1c}6.0%, when each criterion was used for screening as a single test. Among the 6241 study individuals, 410 fulfilled (1) both HbA_{1c}5.7 and IFG100; 135 individuals fulfilled (2) both HbA_{1c}6.0 and IFG100; 159 individuals fulfilled (3) both HbA_{1c}5.7 and IFG110; and only 72 individuals fulfilled (4) both HbA_{1c}6.0 and IFG110. Multivariate adjusted Cox analysis including age, sex, smoking habit, parental history of diabetes, BMI, systolic blood pressure, HDL cholesterol and triglycerides demonstrated that, as compared with normoglycemic individuals, those who fulfilled (1), (2), (3) or (4) had a hazard ratio (HR) of 32.5 (95% CI, 23.0-45.8), 53.7 (38.4-75.1), 37.9 (28.1-51.1), and 52.3 (37.8-72.3) times more increased risk of diabetes, respectively. We observed that the markedly increased risk contributed to a large PAR%; that is, individuals who fulfilled (1), (2), (3) and (4) showed a PAR% of 67%, 53%, 48%, and 37%, respectively (Table 1).

Conclusion: Although the number of pre-diabetic individuals identified by overlap of IFG and elevated HbA_{1c} was small, targeted screening of those with a markedly increased risk could contribute to improve screening efficacy among the total subject population.

Table 1: Hazard ratios for the development of type 2 diabetes according to the baseline diagnosis of pre-diabetes using various cut-offs

Baseline diagnosis of pre-diabetes	n	Age and sex adjusted HR (95% CI)	Multivariate adjusted HR (95% CI)	PAR (%)
IFG100/HbA _{1c} 5.7				
Nomoglycemia	4149	1.00 (Ref.)	1.00 (Ref.)	-
IFG100 alone	1270	6.86 (4.84-9.71)	6.18 (4.34-8.80)	51
HbA _{1c} 5.7 alone	412	6.53 (4.10-10.4)	6.05 (3.79-9.64)	25
IFG100 and HbA _{1c} 5.7	410	38.6 (27.6-54.0)	32.5 (23.0-45.8)	67

Serum levels of vitamin D and abnormal glucose regulation

A. Deleskog, A. Hilding, C.-G. Östenson;

Molecular medicine and surgery, Stockholm, Sweden.

Background and aims: Vitamin D deficiency has been suggested to increase the risk of type 2 diabetes (T2D), but data from prospective studies are scarce and equivocal. The aim of this study was to investigate if development of prediabetes (IFG, IGT) and T2D can be predicted by vitamin D, 25(OH)D, levels. Moreover, we evaluated associations between serum 25(OH)D levels and prediabetes.

Material and methods: The study included 980 women and 1398 men, aged 35–56 years at baseline (1992–98), residing in Stockholm County and participating in a prospective population-based investigation. The subjects were examined by oral glucose tolerance test (OGTT) at baseline and follow up 8–10 years later, classifying the subjects as having normal glucose tolerance (NGT), prediabetes or T2D. Moreover, anthropometric measures, blood pressure and data on lifestyle issues were collected and serum concentrations of 25(OH)D were measured at baseline. At baseline, none had previously diagnosed T2D. All subjects having prediabetes or T2D at follow up were selected as cases. The controls were matched by age and sex to cases by random in a group of subjects having NGT at both baseline and follow up. The association between 25(OH)D levels (adjusted for seasonal variation) and prediabetes/T2D was evaluated by logistic regression analyses, controlling for confounders (age, BMI, FHD, blood pressure, physical activity).

Results: Subjects in the highest quartile of 25(OH)D levels were at baseline, more physically active, had lower 2-h glucose in OGTT, lower BMI and waist circumference compared to subjects in lower quartiles. In the prospective study, men but not women in the highest quartile of serum 25(OH)D had a decreased odds ratio of developing T2D after adjustments (OR=0.57; 95% CI 0.33–0.97). This effect was mainly accounted for by subjects with prediabetes at baseline. Development of prediabetes was not associated with 25(OH)D levels. At baseline, subjects in the highest quartile of serum 25(OH)D had a decreased risk of having prediabetes, however significant only in men after adjustments (OR=0.41, 95% CI 0.25–0.68).

Conclusion: High levels of serum 25(OH)D predict reduced risk of developing T2D in men but not in women. Furthermore, there is a cross-sectional association between prediabetes and low serum 25(OH)D levels mainly in men. Our data suggest that vitamin D supplementation could play a role in prevention of T2D in subjects with prediabetes.

The FINDRISK score is associated with an increase of artery stiffness in prediabetic subjectsA.H. Belhadj Mostefa¹, F. Touati¹, D. Roula¹, P. Valensi²;¹Departement of internal médecine, Constantine, Algeria, ²Departement of Endocrinology, Diabetology, Nutrition, Bondy, France.

Background and aim: Prediabetes is associated with an increased cardiovascular risk. Artery stiffness is an early marker of cardiovascular risk and has been shown to be increased in patients with type 2 diabetes (T2D). The aim was here to look for an association between artery stiffness and the Findrisk score in patients at risk of diabetes.

Materials and methods: We included 222 (166 women) subjects without known dysglycemia but at risk of diabetes (IDF criteria), mean age 50.4 ± 11.4 yrs, BMI 31.9 ± 5.4 kg/m², 65.5% hypertensives. An OGTT was performed, the Findrisk score was calculated, and carotid-femoral pulse wave velocity (PWV) was measured (Complior®).

Results: The prevalence of normal glucose tolerance (NGT), prediabetes (impaired fasting glucose and/or impaired glucose tolerance) and T2D (WHO criteria) was 52%, 29.1% and 18.9%, respectively. A Findrisk score ≥ 14 was strongly associated with current T2D ($p < 10^{-5}$). PWV was higher in T2D and prediabetic patients (10.9 ± 2.9 and 10.6 ± 2.4 m/s) than in NGT patients (9.8 ± 2.5 m/s) ($p < 0.01$). PWV correlated with age and Findrisk score ($p < 10^{-5}$ for both) and was higher in hypertensives than in normotensives ($p < 10^{-5}$). In multivariate analysis, PWV was associated with age and hypertension ($p < 10^{-5}$ in more subjects with a Findrisk score ≥ 14 than in those with a score < 14 (31% vs 6.4%, $p = 0.01$).

Conclusion: In this population at high risk of diabetes, a Findrisk score of 14 or higher is associated with an increase in artery stiffness, even in normotensive subjects. The Findrisk score predicts both current unknown T2D and an increased artery stiffness.

903

Lifestyle modification regulates the expression of glucotransporter 4 (GLUT-4) in prediabetic subjects (PS) and subjects with positive family history of type 2 diabetes (FHS)M.A. Bernat-Karpińska¹, A. Czech¹, P.J. Piątkiewicz¹, P. Wierzbicki², M. Nowaczyk²;¹Department of Internal Diseases and Diabetology, ²Department of Clinical Immunology, Medical University of Warsaw, Poland.

Background and aims: The impairment of cellular glucose transport in insulin resistance state leads to glucose metabolism disturbances. The proper expression of particular GLUT isoforms determines a sufficient glucose supply for tissues. The aim of the study was to evaluate the influence of lifestyle modification on insulin resistance markers and the quantitative expression of GLUT-1, GLUT-3 (typical isoforms for peripheral blood cells) and GLUT-4 (an insulin-dependent isoform) on peripheral blood lymphocytes (PBL) in prediabetic subjects and individuals with positive family history of type 2 diabetes (first-degree relatives) during 24 months of observation.

Materials and methods: The study included 25 PS (diagnosed according to WHO criteria) and 24 normoglycemic FHS. 23 healthy individuals with no family history of type 2 diabetes, matched with age, sex and BMI served as a control group. All participants were treated with diet and exercise intervention at least 140 min. per week. The PBL demonstrating expression of GLUT-1, GLUT-3 and GLUT-4 were labeled with the use of indirect immunofluorescence. The expression of GLUT isoforms was investigated by flow cytometry. Cells were stained by using anti-human GLUT antibodies and FITC-conjugated immunoglobulin. Flow cytometry was performed utilizing a FACSCalibur (Becton-Dickinson). The data was analyzed using Cell Quest software and presented as a percentage of lymphocytes revealing expression of the determined receptor proteins. Additionally we determined: BMI, WHR, fasting plasma glucose (FPG), insulin and C peptide (radioimmunological method), HOMA-IR. All the tests were performed at baseline, after 12 and 24 months.

Results: At baseline PS and FHS were characterized of much higher expression of GLUT-4 compared to control subjects. 24 months of lifestyle modification resulted in significant lowering of the expression of GLUT-4 on the surface of PBL in both studied groups, with no differences in the expression of GLUT-1 and GLUT-3. Both PS and FHS revealed no significant differences in determined insulin resistance markers after 24 months of the observation in comparison to the baseline values. The results were compared using the Aspin-Welch test (Table).

Conclusion: The estimation of typical GLUT isoforms present on the PBL as well as the evaluation of insulin resistance markers are insufficient for monitoring the metabolic disorders progression in PS and FHS. The decrease in GLUT-4 lymphocyte expression proves a positive influence of lifestyle modification on a tissue redistribution of this crucial insulin-dependent glucotransporter. The determination of GLUT-4 on the surface of the PBL can be a useful tool for the evaluation of the therapeutic actions efficacy in subjects at high risk of type 2 diabetes.

@ San Antonio, ⁵Indiana University School of Medicine, Indianapolis,

⁶University of Pittsburgh, Pittsburgh, ⁷Centers for Disease Control, Atlanta,

⁸Johns Hopkins University, Baltimore, ⁹University of Michigan, Ann Arbor,

USA.

The Diabetes Prevention Program (DPP) randomized overweight adults with impaired glucose tolerance (IGT) and an elevated fasting glucose to intensive lifestyle (ILS), metformin (MET), or placebo (PBO) for an average of 3 years. The DPP Outcomes Study (DPPOS) followed participants for an additional 7 years during which time ILS and MET participants were encouraged to continue those interventions and all participants were offered a modified lifestyle intervention. A recent analysis demonstrated that the beneficial effects of ILS and MET on the incidence of type 2 diabetes persisted for at least 10 years after randomization. During both DPP and DPPOS, data on resource utilization, cost, and quality-of-life were collected prospectively. Economic analyses were performed from a health system perspective that considered direct medical costs. During DPPOS, the direct medical costs of ILS and MET were substantially lower than during DPP, and the costs of PBO were higher than during DPP. Over 10 years, the cumulative, undiscounted, per capita direct medical costs of the interventions were greater for ILS and MET than for PBO (\$4,826 ILS vs. \$2,489 MET vs. \$953 PBO). The direct medical costs of care outside the DPP/DPPOS increased over time for all groups, but were highest for PBO. The cumulative undiscounted, per capita, direct medical costs of non-intervention-related medical care were greater for PBO (\$31,299) than MET (\$26,351) or ILS (\$24,759). Over 10 years, the undiscounted per capita total direct medical costs were lower for both ILS (\$29,585) and MET (\$27,840) compared to PBO (\$32,252). Quality-of-life was better for ILS compared to MET or PBO and the undiscounted quality-adjusted life-years accrued over 10 years were greater for ILS (6.81) than MET (6.69) or PBO (6.67 QALYs). Over 10 years, from a payer perspective, ILS and MET were less expensive and more effective than PBO. Both health policy and social policy should support the funding of intensive lifestyle and metformin for diabetes prevention in high-risk adults.

Long-term weight loss with controlled-release phentermine/topiramate reverses metabolic syndrome and improves associated traits

H. Toplak¹, S. Rössner², W.T. Garvey³, B. Troupin⁴, C.H. Bowden⁴;

¹Department of Internal Medicine, Medical University of Graz, Austria,

²Karolinska University Hospital Huddinge, Stockholm, Sweden,

³Department of Nutrition Sciences, University of Alabama at Birmingham,

USA, ⁴VIVUS, Inc., Mountain View, USA.

Background and aims: Abdominal obesity is one of the key features of metabolic syndrome (MetS), and it correlates directly with the associated risk factors. Reducing weight has been shown to decrease the risk of developing MetS and its component comorbidities. In the 56-week CONQUER study, low-dose, controlled-release phentermine/topiramate (PHEN/TPM CR), when added to lifestyle interventions, demonstrated significant weight loss and resolution of MetS. SEQUEL, a 52-week extension study in subjects completing CONQUER, evaluated the long-term effects of PHEN/TPM CR on weight loss and the components of MetS.

Materials and methods: SEQUEL (N=675) maintained the original randomization and blinding of CONQUER (placebo, PHEN 7.5 mg/TPM CR 46 mg [7.5/46], and PHEN 15 mg/TPM CR 92 mg [15/92]). This subanalysis evaluated weight loss and changes in MetS status in SEQUEL subjects who had MetS at CONQUER baseline (Week 0). MetS was defined (by the US MetS criteria) as presence of ≥3 of the following 5 risk factors: waist circumference ≥102 cm in men, ≥88 cm in women; triglycerides ≥1.7 mmol/L; HDL cholesterol (HDL-C) <1.03 mmol/L in men, <1.3 mmol/L in women; systolic BP ≥130 mmHg or diastolic BP ≥85 mmHg; and fasting glucose ≥5.6 mmol/L. **Results:** At Week 0, 59.3% (n=400) of SEQUEL subjects met the criteria for MetS (placebo, n=141; 7.5/46, n=86; 15/92, n=173) with a similar distribution of number of risk factors (3, 4, or 5) within each group at baseline. For subjects with MetS at baseline, least-squares (LS) mean percent weight loss at Week 108 was significantly greater for both doses of PHEN/TPM CR compared with placebo: 2.8%, 10.0%, and 10.8% for placebo, 7.5/46, and 15/92, respectively (intent-to-treat with last observation carried forward; P<0.0001). After 108 weeks, more subjects receiving PHEN/TPM CR no longer met the criteria for MetS than those receiving placebo: 44.7%, 51.2%, and 57.2% for placebo, 7.5/46, and 15/92, respectively (P=0.0269 for 15/92 vs placebo). Conversely, in subjects without MetS at baseline (n=274), progression to MetS was 27.9% with placebo vs 14.9% and 6.6% with 7.5/46 and 15/92, respectively (P<0.0001 for 15/92 vs placebo). At Week 108, more subjects receiving PHEN/TPM CR saw a decrease in the number of MetS component traits compared with placebo (P<0.05). Treatment with 15/92 resulted in greater improvements in most of the individual components of MetS (fasting glucose, triglycerides, HDL-C, and waist circumference when compared with placebo (P<0.05 for all comparisons). PHEN/TPM CR was generally well tolerated, with an overall completion rate of 84% on study drug. The most common treatment-emergent adverse events (upper respiratory tract infection, constipation, and paraesthesia) were similar to those experienced during CONQUER, although the overall incidence was lower in the extension.

Conclusion: In subjects with MetS at baseline, PHEN/TPM CR-treated subjects demonstrated sustained weight loss after 108 weeks that was significantly associated with resolution of the MetS diagnosis in more than half of PHEN/TPM CR-treated subjects and resulted in improvements in the individual components of MetS.

Long-term glycaemic effects of weight loss with low-dose, controlled-release phentermine/topiramate (PHEN/TPM CR) in overweight/obese subjects with diabetesL.F. Van Gaal¹, L.J. Cheskin², T. Najarian³, W.W. Day³, C.A. Peterson³;¹Department of Endocrinology and Diabetology, Antwerp University Hospital, Edegem, Belgium, ²Department of Health Behavior & Society, Johns Hopkins Weight Management Center, Baltimore, MD, USA, ³VIVUS, Inc., Mountain View, CA, USA.

Background and aims: Obesity is a major public health problem associated with type 2 diabetes mellitus (T2DM). An investigational combination of PHEN/TPM CR demonstrated significant weight loss and improvement in glycaemic parameters in the 56-week CONQUER study involving 2487 adults with ≥ 2 weight-related comorbidities. SEQUEL, a blinded 52-week extension of CONQUER, was conducted to determine long-term safety, weight loss, and glycaemic effects of PHEN/TPM CR at 108 weeks.

Materials and methods: SEQUEL (N=675) maintained the randomization from CONQUER, with subjects receiving placebo (n=227), PHEN 7.5 mg/TPM CR 46 mg (7.5/46, n=153), or PHEN 15 mg/TPM CR 92 mg (15/92, n=295); all subjects also received lifestyle counseling. Subjects with T2DM could be treatment-naïve or receiving metformin monotherapy; they were managed per ADA standards of care, which included the potential for changes in their antidiabetic treatment regimen.

Results: Within the SEQUEL population, 145 (21.5%) subjects had T2DM at baseline. At Week 108, least-squares (LS) mean percent weight loss in the intent-to-treat population with last observation carried forward was 1.8%, 9.3%, and 10.5% for placebo, 7.5/46, and 15/92, respectively ($P<0.0001$ vs placebo). In subjects with T2DM, LS mean percent weight loss at 108 weeks was 2.0%, 9.0%, and 9.0% for placebo, 7.5/46, and 15/92, respectively ($P<0.0005$ vs placebo). Glycaemic improvements in T2DM subjects at 108 weeks were greater in the PHEN/TPM CR treatment groups, although the differences were not statistically significant (Table). In addition, a trend towards reduction of concomitant antidiabetic medications was evident in PHEN/TPM CR-treated subjects. At Week 108, 3.1% of the 15/92 group had reduced their antidiabetic medications compared with 1.3% of placebo subjects; a greater percentage of placebo-treated subjects increased their medications vs the 15/92 group (8.4% and 3.1%, respectively; $P=0.0130$ for between-group differences). Overall completion rate was 84%. Common adverse events were constipation, dry mouth, paresthesia, and dysgeusia. The pattern across treatment groups was similar to that reported in Week 56 of the CONQUER trial, although overall incidence rates were lower at 2 years.

Conclusion: Long-term (2-year) weight loss observed with PHEN/TPM CR was associated with sustained improvements in glycaemic parameters in subjects with T2DM, with treated subjects demonstrating a trend towards reduction of antidiabetic medication use. These data suggest that PHEN/TPM CR has the potential to bring about sustained weight loss, improved glycaemic status, and decreased concomitant antidiabetic medication use in obese subjects with T2DM.

Table. LS Mean Change in Glycaemic Parameters at Week 108 (T2DM Population)

	Placebo	7.5/46	15/92
HbA1c (%)	-0.04	-0.42	-0.23
Fasting glucose (mmol/L)	-0.35	-0.59	-0.41
Fasting insulin (pmol/L)	-29.52	-52.02	-43.48

Decreased progression to diabetes in subjects with prediabetes after 2 years of treatment with controlled-release phentermine/topiramateW.T. Garvey¹, B. Troupin², W.W. Day²;¹Department of Nutritional Sciences, University of Alabama at Birmingham, ²VIVUS, Inc., Mountain View, USA.

Background and aims: Obesity can cause impaired glucose metabolism, and those obese patients who meet criteria for prediabetes, defined as impaired fasting glucose ≥ 5.55 and ≤ 6.94 mmol/L) or impaired glucose tolerance (oral

glucose tolerance test ≥ 7.77 and ≤ 11.0 mmol/L), are at a particularly high risk of developing type 2 diabetes (T2DM).

Materials and methods: The SEQUEL study assessed the long-term ability of controlled-release phentermine plus topiramate (PHEN/TPM CR) to induce and sustain weight loss and to impact weight-related comorbidities. SEQUEL was a 52-week extension in subjects completing the 56-week CONQUER study and maintained the original randomization and blinding from CONQUER (placebo, PHEN 7.5 mg/TPM CR 46 mg [7.5/46], and PHEN 15 mg/TPM CR 92 mg [15/92]). All subjects (PHEN/TPM CR and placebo) received lifestyle intervention for weight loss and were actively managed to standard of care throughout the 2 year treatment period. This prespecified subanalysis evaluated weight loss and changes in glycaemic status in SEQUEL subjects who had prediabetes at CONQUER baseline (Week 0, n=316). All analyses reflect changes from baseline (Week 0) to Week 108.

Results: After 108 weeks of treatment, least-squares (LS) mean percent weight loss in patients with prediabetes was significantly greater with both doses of PHEN/TPM CR plus lifestyle vs placebo plus lifestyle intervention ($P<0.0001$; intent-to-treat with last observation carried forward): 2.2%, 11.1%, and 12.7% for placebo (n=103), 7.5/46 (n=83), and 15/92 (n=130), respectively. More subjects with prediabetes who were treated with 15/92 achieved normoglycaemia than those receiving placebo (54.6% vs 33.0%, $P=0.0004$ vs placebo). PHEN/TPM CR 15/92 also dramatically reduced rate of progression to T2DM when compared with placebo (0.8% vs 5.8%; $P=0.0004$). Effects of 7.5/46 were not significantly different from placebo in the prediabetic subpopulation ($P=0.5930$ vs placebo), with the 15/92 dose being statistically superior to 7.5/46 on both measures ($P<0.01$ vs 7.5/46). Dose-related improvements in fasting insulin (pmol/L) at Week 108 were observed with PHEN/TPM CR when compared with placebo: LS mean change of -19.4, -34.6, and -38.2 for placebo, 7.5/46, and 15/92, respectively ($P=0.0314$ vs placebo for 15/92). PHEN/TPM CR was well tolerated, with a higher percentage of eligible CONQUER subjects on 15/92 (86%) choosing to enrol in the extension than either 7.5/46 (79%) or placebo (69%). Common adverse events over the 108 weeks were upper respiratory tract infection, constipation, dry mouth, paresthesia, and dysgeusia; the pattern was similar to that experienced at Week 56 of CONQUER, with lower overall incidence rates at 2 years.

Conclusion: In subjects with prediabetes, PHEN/TPM CR plus lifestyle intervention was associated with substantial weight loss that was maintained over 108 weeks compared to lifestyle intervention alone. PHEN/TPM CR also led to improvements in glycaemia and decreased hyperinsulinemia, and PHEN/TPM CR 15/92 markedly decreased the rate of progression to overt T2DM.

Legacy analysis of STOP-NIDDM substudy: 9-year follow-up investigation after end of trialF. Schaper¹, C. Koehler¹, E. Henkel¹, J. Stelzer¹, R. Staudte¹, J.-L. Chiasson², H. Stein³, M. Hanefeld¹;¹Centre of clinical studies, GWT-TUD, Dresden, Germany, ²University of Montreal, Canada, ³Bayer Healthcare, Leverkusen, Germany.

Background and aims: Postprandial (pp) hyperglycemia is a major risk factor for cardiovascular disease (CVD). Acarbose, an α -glucosidase inhibitor, specifically reduces pp glucose excursion. It could be shown in the Study To Prevent Noninsulin-Dependent Diabetes Mellitus (STOP-NIDDM) that acarbose treatment in IGT reduces the risk of diabetes (DM) by 36% if the criteria of DPP were used. Furthermore in a substudy with intima media thickness (IMT) measurement we could demonstrate that control of pp hyperglycemia with acarbose was able to achieve non-progression of IMT after a follow-up time of 3.9 years. The objective of this legacy study was to determine whether administration of acarbose can delay or prevent the progression of IMT of common carotid arteries (CCA) after the end of the trial. Secondary objectives were newly diagnosed DM and hypertension.

Materials and methods: The STOP-NIDDM trial was a multinational double-blind placebo-controlled study with a total number of 1429 eligible subjects randomized to receive either 100 mg acarbose 3 times a day or placebo. Our single-center STOP-NIDDM substudy was based on 132 participants, recruited in Dresden, Germany. In the legacy investigation the patients who took part in the sub-study were examined by ultrasonography of the distal CCA as originally described by Pignoli. Patients without diagnosed DM received an OGTT with 75g glucose. Anamnestic data were collected and weight, blood pressure and HbA1c were measured.

Results: All 132 patients who completed the sub-study were contacted for the legacy visit, 8 patients were lost to follow-up and 14 rejected to participate at the legacy visit, 11 patients died (6 in Acarbose (A) group and 5 in placebo (P) treatment (n.s.)). A set of 99 patients was examined altogether in the legacy visit, 12 patients were excluded because of missing IMT data. Finally we analyzed data of 43 subjects in A and 44 in P with an average follow-up time of 9.8 yrs. At the legacy visit IMT was similar in both groups (0.81 ± 0.12 (A); 0.80 ± 0.14 mm (P)). We found an increase in HbA1c from 5.5% to 6.2% (A) and 6.0% (P), 34.4% of the patients developed DM (n.s. between the groups) after the end of the trial; and 19.5% developed hypertension. After the trial only 4 patients were treated with acarbose in the follow-up time.

Conclusion: We found no significant difference in IMT after 10 years follow-up without acarbose. Otherwise our results indicate that lower incidence of DM and hypertension at the end of the STOP-NIDDM trial was due to treatment of IGT with acarbose rather than a result of primary prevention. Patients with IGT plus IFG seen in the STOP-NIDDM trial represent a high risk group for DM and hypertension. By extrapolation of the trial and posttrial results our data suggest that such high risk patients should be considered for long term treatment with acarbose.

PS 078 Established treatments in type 1 and type 2 diabetes

909

Initial sulphonylurea monotherapy led to more frequent and earlier initiation of insulin therapy in older patients with type 2 diabetes mellitus

Y. Qiu¹, A.Z. Fu², M.J. Davies¹, S.S. Engel¹;

¹Merck Sharp & Dohme Corp., Whitehouse Station, ²Cleveland Clinic, Cleveland, USA.

Background and aims: In type 2 diabetes mellitus (T2DM), the progressive loss of β -cell function over time requires treatment intensification and eventually initiation of insulin in many patients. Relative to metformin, a greater rate of decline in β -cell function over time has been observed with sulphonylurea treatment. The present study examined the association between initial monotherapy with metformin or sulphonylurea and subsequent initiation of insulin in older patients with T2DM.

Materials and methods: In a retrospective cohort study using the GE electronic medical record database, eligible patients with T2DM included those ≥ 65 yrs who received their first prescription of sulphonylurea or metformin as initial monotherapy between 2003 and 2008. The follow-up lasted to the end of 2009 or the patient's latest data available. Insulin initiation was determined by prescription records. Logistic regression analysis evaluated the likelihood of insulin addition. Cox regression model estimated time to initiation of insulin. Differences in baseline characteristics (demographics, clinical and laboratory measures, and comorbidities) were controlled for using propensity score matching (PSM).

Results: Overall, 12,036 patients were included in the analysis with 6,018/group. Mean age was 75 yrs and 50% were male. While controlling for differences in baseline characteristics using PSM, patients who initiated with sulphonylurea had a significantly ($p < 0.001$) higher incidence of insulin addition (2.8% vs. 1.4%) compared to those initiated with metformin after 1 year of follow up. The likelihood of initiating insulin was higher in patients initiated with sulphonylurea than with metformin (odds ratio [95% CI] = 1.96 [1.51, 2.55]; $p < 0.001$). Sulphonylurea use was also significantly associated with shorter time to insulin use compared to metformin (hazard ratio [95% CI] = 2.20 [1.91, 2.52]; $p < 0.001$). The rate of insulin addition remained significantly higher ($p < 0.001$) with initial sulphonylurea monotherapy vs. metformin after 2 and 3 yrs of follow-up (6.1% vs. 2.6%, and 8.1% vs. 3.9%, respectively).

Conclusion: In a cohort of older patients with T2DM initiating antihyperglycaemic therapy, patients who started with sulphonylurea monotherapy received insulin therapy more frequently and earlier than those who started with metformin.

Association of sulfonylurea with overall and cardiovascular mortality: a systematic review and meta-analysis

T. Forst¹, G. Möser², A. Haupt³;

¹ikfe Institute for Clinical Research and Development, Mainz, ²masem research institute, Giessen, ³Lilly Deutschland GmbH, Bad Homburg, Germany.

Background and aims: Sulfonylureas (SU) are widely used for treatment of type 2 diabetes mellitus (T2DM). Recent reports have re-enforced the debate that SU treatment might be associated with an increased cardiovascular (CV) mortality in T2DM patients. We conducted a systematic review and meta-analysis to evaluate the overall and CV mortality of T2DM patients receiving SU versus any other diabetes treatment, including insulin.

Materials and methods: We performed a systematic research through electronic medical databases (MEDLINE, EMBASE) to identify any studies on SU and CV disease, and on SU and mortality, from inception through December 2010, and an additional hand search for relevant studies. Observational studies and randomised trials were included in the meta-analysis if they reported raw data on overall or CV mortality during SU treatment in T2DM patients. Randomised studies were included only if the SU treatment period lasted > 12 months. Raw data were combined using a random-effects model. Results are presented as odds ratios (ORs) and corresponding 95% confidence intervals (CIs).

Results: Of 4,828 study titles and abstracts reviewed, data from 19 studies were included in the final analysis, comprising a sample of more than 230,000 patients overall. SU single agent or combination treatment was associated with increased overall and CV mortality risk when compared to any non-SU treatment. Overall mortality, based on 18 studies, was: OR 1.39, 95% CI 1.13–1.71. CV mortality, based on 7 studies, was: OR 1.68, 95% CI 1.17–2.43. Single agent SU treatment was associated with even higher ORs for overall and CV mortality when compared to single agent metformin treatment. Overall mortality, based on 14 studies, was: OR 2.04, 95% CI 1.60–2.60. CV mortality, based on 6 studies, was: OR 2.52, 95% CI 1.75–3.63. The validity of the pooled OR estimates was limited by the high level of heterogeneity across studies ($I^2 > 90\%$), and the inherent biases and differences in study designs of the observational studies included.

Conclusion: SU treatment was associated with significant increases in overall and CV mortality. Although this meta-analysis was limited by the high heterogeneity of the studies included, patients and physicians need to consider the potential increase in mortality risk when using SU for T2DM treatment. Acarbose or nateglinide for decreasing postprandial glucose excursions: key predictive factors identified by continuous glucose monitoring (CGM)

H. Shimura, M. Kaneshige, S. Takizawa, C. Suzuki, M. Ichijo, S. Ichijo, A. Okamura, F. Furuya, S. Tanaka, K. Ohta, K. Aida, T. Kobayashi; Third Department of Internal Medicine, University of Yamanashi, Japan.

Background and aims: Postprandial glucose excursion contributes to the development of microvascular and macrovascular complications in any type of diabetes. Short-acting insulin secretagogue, nateglinide, and α -glucosidase inhibitor, acarbose, are commonly used for postprandial hyperglycemia in patients with type 2 diabetes. However, there is no report examining specific glucose excursions in patients treated with these antidiabetic agents and key clinical factors, which contribute to predict those effect on reduction of postprandial glucose excursions. In the present randomized clinical study, we examine the ability of acarbose and nateglinide to improve postprandial hyperglycemia by continuous glucose monitoring (CGM). We tried to identify key clinical factors based on which we can predict the effectiveness of nateglinide and acarbose to reduce postprandial hyperglycemic excursion in type 2 diabetes.

Materials and methods: We performed a randomized clinical trial assigned 11 patients with type 2 insulin-independent diabetes with postprandial hyperglycemia. CGM was performed using the CGMS-gold system (Medtronic) for three days. On the first day, glucose excursions with no medication were analyzed. The participants were then randomly assigned to two groups. In the first group, acarbose 100 mg or nateglinide 90 mg three times daily were administered on day 2 and 3, respectively, and vice versa in the second group. A standardized 460 kcal meal was used as a breakfast during the study period.

Results: The CGM data showed that the mean glucose value in the day with acarbose was lower than that with nateglinide in 4 of 11 participants. In remaining 7 participants, nateglinide exhibited a predominant effect on reducing mean glucose value. Other measures of glycemic excursions including standard deviation and AUC above 140 mg/dl of CGM measurements showed significant correlations with the mean glucose value ($p < 0.05$). Therefore, the participants could be divided into two groups: the acarbose-remediable group and nateglinide-remediable group based on the mean glucose value. Analysis of basal clinical and laboratory data including fasting blood glucose levels, HbA1c, fasting IRI, HOMA-IR, HOMA- β , serum fasting C-peptide, IRI, urinary C-peptide excretion, BMI, age, and duration of diabetes, revealed that serum fasting C-peptide was significantly different between the two groups ($p < 0.05$). The serum C-peptide level was 1.18 ± 0.18 ng/ml (mean \pm SD, 95% CI -0.89–1.47) or 2.44 ± 0.83 ng/ml (1.65–3.23) in the acarbose- or nateglinide-remediable group, respectively. A cut-off value of C-peptide set at 1.5 ng/ml can distinguish the remediable agent with 100% sensitivity and specificity.

Conclusion: In type 2 diabetes patients who maintained ability of insulin secretion (serum C-peptide ≥ 1.5 ng/ml), nateglinide exhibited a higher suppressive effect on postprandial hyperglycemia rather than acarbose. In contrast, patients with a decreased ability of insulin secretion (serum C-peptide < 1.5 ng/ml) should be treated with acarbose, since the effect of acarbose is independent of the ability of insulin secretion.

The improvement of endothelial function in type 1 diabetic subjects treated with metformin is independent by its glycometabolic effects

G. Scavone, F. Zaccardi, P. Tarzia, M. Milo, R. Nerla, A. Di Monaco, D. Pitocco, G.A. Lanza, F. Crea, G. Ghirlanda; Catholic University, Rome, Italy.

Background and aims: Impaired endothelial function is considered an early sign of atherosclerosis in patients with type 1 diabetes (T1DM). Tight glycaemic control using intensive insulin therapy was shown to reduce rates of vascular complications in T1DM. No study had already assessed the effect of metformin, an oral biguanide glucose-lowering agent, widely used in the treatment of type 2 diabetes, on vascular function, in patients with T1DM.

Materials and methods: We enrolled 35 T1DM patients (age 36.2 ± 5.9 , 20 M) without any overt cardiovascular disease, similar for clinical and laboratory variables. Patients were randomized to receive 3x850 mg of metformin (M-group, n=20), or placebo (P-group, n=15) in addition to their standard daily therapy. Peripheral endothelial function was assessed, at baseline and at a 6-month follow up, by measuring right brachial artery dilation during post-ischemic forearm hyperemia (flow mediated dilation, FMD) and in response to administration of 25 μ g of sublingual glyceryl trinitrate (nitrate-mediated dilation, NMD).

Results: At baseline FMD and NMD were similar in the 2 groups (respectively, FMD values were: $7.7 \pm 2.7\%$ in M-group vs. $8.5 \pm 3.3\%$ in P-group, $p=0.3$; NMD values were: $10.1 \pm 2.5\%$ in M-group vs. $10.3 \pm 2.8\%$ in P-group, $p=0.7$). Compared to baseline, FMD at follow-up improved significantly in M-group patients ($8.6 \pm 2.7\%$, $p < 0.01$) but not in P-group patients ($8.5 \pm 2.9\%$, $p=0.9$). No change was observed for NMD. Moreover, glycemic variability (CONGA1-5 and standard deviation) did not change significantly in both M and P-group.

Conclusion: Metformin improves endothelial function independently by its metabolic effects. Further investigations about the potential cardiovascular-protective effects of metformin therapy in patients with T1DM are warranted.

913

Changes in arterial stiffness and circulating adiponectin during one-year metformin treatment for nonalcoholic steatohepatitis: beyond glucose control improvement

M. Shargorodsky, E. Omelchenko, M. Mashavi, Z. Matas, M. Boaz, D. Gavish; Wolfson medical center, Tel Aviv University, Israel.

Methods and aims: Insulin resistance (IR) is the major driving force behind development and progression of atherosclerosis in patients with nonalcoholic fatty liver disease (NAFLD). Therefore, correction of IR is a relevant therapeutic target. We performed the current trial to assess whether 12-month metformin therapy improves vascular stiffness in patients with NAFLD, assess if this improvement is associated with change in glucose control, insulin level and circulating adiponectin.

Methods: In randomized, placebo controlled study, 63 patients with NAFLD were assigned to one of two groups: Group 1 received daily metformin; Group 2 received placebo. Pulse wave velocity (PWV) and augmentation index (AI) were performed using SphygmoCor (version 7.1, AtCor Medical, Sydney, Australia) at baseline, at 4- and 12-month treatment period. Metabolic parameters, insulin resistance markers and serum adiponectin levels were determined.

Results: Among metformin treated patients: PWV and AI decreased significantly during the study. In placebo group: neither PWV nor AI improved significantly during the treatment period. Change from baseline AI as well as PWV was significantly greater in patients treated with metformin than in the placebo group ($p < 0.002$ and $p < 0.001$, respectively). The decrease from baseline HOMA-IR as well as HbA1C was marginally greater in the active treatment group compared to the placebo group. In multiple linear regression analysis, the independent predictors of arterial stiffness improvement were metformin treatment and increase in circulating adiponectin levels.

Conclusion: Metformin treatment was associated with significant decrease in PWV and AI in NAFLD patients. This beneficial vascular effect was associated with increase in circulating adiponectin levels suggesting that adiponectin is an important mediator of the insulin-sensitizing effects of metformin.

Clinical Trial Registration Number: NCT01084486

Pharmacological characterisation of metformin-induced intestinal contraction

S. Silva^{1,2}, A. Henriques^{1,3}, L. Carvalho⁴, R.M. Seica⁵, C. Fontes-Ribeiro²;¹Centre of Pharmaceutical Studies, Faculty of Pharmacy, ²Pharmacology and Experimental Therapeutics (IBILI), Faculty of Medicine, ³Department of Life Sciences, Faculty of Sciences and Technology, ⁴Institute of Pathology, Faculty of Medicine, ⁵Institute of Physiology, Faculty of Medicine, Coimbra, Portugal.

Background and aims: Diarrhea is one of the side effects commonly reported with metformin treatment. The cause of diarrhea is unknown. The aims of this study were: 1. To determine the contractile response of the rat isolated ileum to metformin and characterize pharmacologically the mediating receptor. 2. To verify the possible changes of the metformin-induced intestinal contraction in diabetic (DM) rats.

Materials and methods: Ileum segments isolated from male Wistar rats were prepared for isometric contractile concentration-response (CR) curves (not cumulative) for metformin (1–36 μ M) and 5-HT (0.1–60 μ M). Frequency-response (FR) curves were obtained through electrical field stimulation (EFS). Two successive CR curves were performed, after 100 μ M acetylcholine; 15 min before each dose of the second CR curve, 10 μ M atropine, 1 μ M mepyramine, 1 μ M ketanserin, 1 μ M SB 224,289, 1 μ M ritanserin or 1 μ M methiothepin were added; 300 μ M hexamethonium, 1 μ M tetrodotoxin (TTX) and 250 μ M NG-nitro-L-arginine were added. The same procedure was performed in Goto-Kakizaki (GK) rats, a non-obese animal model of DM2. In each assay, control segments were used with the appropriate solvent of each drug. Ileum segments were also used for histological section and immunohistochemical techniques to study the immunoreactivities of 5-HT1B and 5-HT2A receptors.

Results: Metformin, in therapeutic levels (6–36 μ M), caused concentration-dependent contractions (E_{max} of 12.20 ± 0.79 mN, $n=48$; pEC_{50} of 4.89 ± 0.034 , $n=47$); 36 μ M metformin did not significantly change the rat ileum frequency-dependent contractile response to EFS suggesting a non-neuronal mechanism of action, which was confirmed by the unchanged metformin CR curve in the presence of hexamethonium and TTX. Moreover, the metformin CR curve was not significantly altered by atropine nor by NG-nitro-L-arginine, excluding the involvement of muscarinic receptors or NO, but mepyramine, an inverse agonist of the H1 histamine receptor, did significantly change the metformin-induced contraction. Concerning 5-HT receptors, ketanserin and SB 224,289 did not change the metformin-induced contraction, which means that 5-HT_{2A/2C} and 5-HT_{1B} receptors are not involved. However, methiothepin (a non-selective 5-HT receptors antagonist) and ritanserin (a non-selective 5-HT₂ antagonist), almost abolished the metformin-induced intestinal contraction which proves the involvement of 5-HT receptors, namely 5-HT_{2B} receptors. The effects of ketanserin and ritanserin on the metformin CR curve were also observed on the 5-HT CR curve. Furthermore the immunohistochemical studies did not reveal any immunoreactivity for the 5-HT_{2A} receptor on the smooth muscle layers. In GK rats the ritanserin reduction of the metformin-induced intestinal contraction only became significant at the last metformin dose of the CR curve.

Conclusion: Since in the gut about 90% of serotonin is synthesized, stored and released mainly by enterochromaffin cells, we propose that metformin may trigger the release of monoamines from enterochromaffin cells and that somehow their function is impaired in the presence of DM2.

915

Pleiotropic effects of add-on therapy with pioglitazone, metformin or the combination of both in patients with type 2 diabetes on stable insulin glargine therapy

I.E. Kleine¹, W. Fuchs¹, A. Pfuetzner², T. Forst⁴, M. Hanefeld³;¹Medical, Takeda Pharma GmbH, Aachen, ²ikfe GmbH, Mainz, ³GWT-TUD mbH, Dresden, Germany.

Patients with long-term type 2 diabetes and stable insulin therapy still exhibit a high cardiovascular (CV) risk as recently shown in the DIGAMI2 study. Here we analyzed specific effects of add-on therapy with pioglitazone in comparison with metformin and their combination in type 2 diabetes patients on high CV risk under acceptable HbA_{1c} control with basal insulin glargine. In this double-blind, randomized, active comparator controlled trial 121 patients with type 2 diabetes were included. Main inclusion criteria were stable insulin treatment with basal insulin glargine, HbA_{1c} > 6.5% and < 8.5%, and

an age of 30–75 years. The patients were 63.0 (\pm 7.5) years old with BMI of 32.2 (\pm 5.3) kg/m², HbA_{1c} of 7.34 (\pm 0.53) %, insulin glargine dosage of 36.2 (\pm 20.9) units, hsCRP of 3.21 (\pm 2.54) mg/L, and Matrix Metal Proteinase (MMP-9) of 566.0 (\pm 266.2) ng/mL at baseline. Main comorbidities were hypertension in 87.6 % and CVD in 19.0 %. After a run-in period of >2 weeks with glargine monotherapy titrated to FBG < 7.8 mmol/l patients were randomized to either (1) bid 850 mg metformin, (2) bid 15 mg pioglitazone, or (3) 30 mg pioglitazone plus 1.7 g metformin for a 6-month treatment phase. Primary objective was MMP-9, secondary objectives were glucose control and specific biomarkers of inflammation and oxidative stress.

Results: Our data show that these patients despite insulin treatment exhibit an increased inflammatory activity, but normal PGF₂ α excretion.

a= $p < 0.05$ and b= $p < 0.01$ for Met vs. Pio / * = $p < 0.05$ and ** = $p < 0.01$ for within group comparisons

The addition of pioglitazone but not metformin significantly reduced MMP-9, hsCRP, E-Selectin and Leucocytes and increased insulin sensitivity and adiponectin independent from glycemic control.

The triple combination of pioglitazone with metformin resulted in better HbA_{1c} without added effect on inflammation and fibrinolysis. No serious adverse events were observed. Hypoglycemic episodes were seen in 21.4% vs. 20.0% vs. 28.2%, weight change was -0.7kg vs. +4.3kg vs. +2.7kg, and peripheral edema was observed in 11.9% vs. 40.0% vs. 20.5% in groups 1 vs. 2 vs. 3. Pioglitazone is suggested to be a rational add-on therapy to basal insulin in patients with high cardiovascular risk as it closes a gap in prevention by correction of increased inflammatory activity.

Effects of the combination therapy of pioglitazone with insulin glargine on low density lipoprotein subfractions in patients with type 2 diabetes: the PIOcomb Study

C. Koehler¹, J. Graessler², W. Fuchs³, T. Forst⁴, A. Pfuetzner⁴, E. Henkel¹,S. Nitzsche², C. Hohberg⁴, J. Mueller⁵, I.E. Kleine³, R. Staudte¹, M. Hanefeld¹;¹Center for Clinical Studies, GWT-TUD GmbH, Dresden, ²Medical Clinic III, University Hospital Carl Gustav Carus, Dresden, ³Takeda Pharma GmbH, Aachen, ⁴ikfe GmbH, Mainz, ⁵acromion GmbH, Frechen, Germany.

Background and aims: Type 2 diabetes (T2DM) is strongly associated with dyslipidemia and insulin resistance. Thiazolidinediones such as pioglitazone has been shown to improve in addition to blood glucose lowering the insulin resistance and atherogenic lipoprotein profiles. The aim of this study was to investigate the efficacy of addition of pioglitazone (PI) (vs. metformin (MI)

and vs. their combination (PMI)) to stable insulin glargine therapy in patients with T2DM on atherogenic small dense LDL particles, cholesterol particle load and particle number.

Materials and methods: Eligible patients using insulin glargine basal were randomized in this double-blind, prospective, 3-arm study and received an optimized therapy with insulin glargine plus metformin (2x850mg/day, N=39), pioglitazone (2x15mg/day, N=37) or plus the combination of both OAD (N=37) over 6 months. The LDL subfractions were isolated by very fast ultracentrifugation in VLDL, LDL1-3 and HDL. Insulin resistance was calculated by HOMA_IR model. The matrix metal proteinase 9 (MMP9) a marker for plaque stability was measured.

Results: A total of 113 (72 males, 41 females) were enrolled in the study with an average age of 63±7 years, BMI 31.9±5.2kg/m², HbA1c 7.3±0.5% and duration of diabetes 12.3±6.8 years. Overall LDL-cholesterol remained nearly unchanged by individual add on therapy. However determination of LDL-subfractions revealed distinct differences in effects on lipoprotein profile. PI treatment caused significant lowering of cholesterol concentration in atherogenic small dense LDL3 (density 1.040–1.066g/l) (change -48μmol) and increased cholesterol in HDL (+130μmol/l) after 6 months therapy while it increased with MI (+49μmol/l, n.s.). The PMI therapy decreased the cholesterol in LDL3 (change -36μmol/l, n.s.). In addition we found a significant change of cholesterol load per LDL3 particle of: -61.6mol/mol in the PI group, +86.4mol/mol in the MI group and -37.1 mol/mol in the PMI group. Vice versa we found an increase in cholesterol in LDL1 after PI therapy and a decrease in the MI group. In multivariate regression model with HOMA_IR (end of treatment) as dependent variable was found female gender, cholesterol concentration in all LDL subclasses, MMP9 and the study treatment (MI) as independent risk marker.

Conclusion: The comparison between MI vs. PI vs. PMI showed a decrease of cholesterol in small dense LDL and in LDL3 particle cholesterol load and a shift to LDL1 after 6 months PI therapy. These data suggest that in type 2 diabetic patients with high cardiovascular risk pioglitazone as add on therapy has beneficial effects on atherogenic lipoprotein profile and the insulin resistance whereas this was not achieved with metformin.

Phenotypic and functional ex vivo characterisation of endothelial progenitor cells and effects of the PPAR-γ agonist pioglitazone

A. Dei Cas¹, V. Spigoni¹, A. Picconi¹, V. Ridolfi¹, C. Casali¹, E. Usberti¹, I. Lambertini¹, L. Gnudi², M. Metra³, I. Zavaroni¹;

¹Internal Medicine and Biomedical Sciences, University of Parma, Italy,

²Cardiovascular Division, King's College, London, UK, ³Department of Experimental and Applied Sciences, University of Brescia, Italy.

Background and aims: Impairment in the number and function of endothelial progenitor cells (EPCs) has been implicated in the pathogenesis of cardiovascular (CV) disease in conditions characterized by an increased CV risk such as diabetes and insulin resistance. We recently demonstrated that EPC number is also reduced in subjects with subclinical insulin resistance. The PPAR-γ agonist pioglitazone, exerts beneficial CV effects that extend beyond its anti-hyperglycemic effects. Due to the lack of a standardised method for EPC identification, we first carried out a phenotypic and functional *ex vivo* EPC characterization. We subsequently investigated whether the CV beneficial effects of pioglitazone are mediated by an improvement in EPC biology independently of its metabolic action

Materials and methods: We conducted experiments for *ex vivo* isolation of two types of EPCs, namely early and late-outgrowth EPCs, obtained through different culture methods and times. Early EPCs were obtained after culturing lymphomonocytes on fibronectin-coated dishes in EGM-2 medium for 7 days. In the same culture conditions late-outgrowth EPCs were obtained after 3–4 weeks. Early and late-outgrowth EPCs were phenotypically characterized by immunofluorescence and FACS analyses. Specific endothelial proprieties such as acLDL uptake and lectin binding capacity were tested. Tubular formation assay was performed by co-plating cells on Matrigel with HUVEC to test EPC function. Pioglitazone (10μM) or PPARγ antagonist GW9662 were added to the culture media to test the effects of the drug on EPC viability/proliferation (VisionBlue-Quick cell viability assay kit), apoptosis and function.

Results: Early EPC showed the co-expression of monocyte-macrophage (CD14, CD11b, CD44) and endothelial cell-surface (CD31, KDR) markers and co-operated to tube formation. Late out-growth EPCs showed a higher expression of CD34 and of mature endothelial cell-surface markers (CD31, KDR, CD146, CD105). Late out-growth EPCs were able to form colonies and

were capable of autonomously forming tubular-like structures on Matrigel. The addition of pioglitazone improved early and late EPC proliferation by 20% and 100% respectively compared to the antagonist-containing and control cultures. No difference in apoptosis induction was observed in the different culture conditions. In the presence of pioglitazone EPCs showed a more elongated shape and the expression of adhesion (PECAM and ICAM-1) molecules was reduced. We are currently analysing data from the tubular formation assays.

Conclusion: Our data, although preliminary, suggest a putative direct beneficial effect of pioglitazone on EPC biology with potential therapeutic implications. Morphological and phenotypical changes of early-EPCs might suggest a protective effect of pioglitazone on the vascular system.

Predicting long-term HbA_{1c} efficacy from early steady-state FPG responses: a model-based meta-analysis of anti-diabetic treatments

S. Neelakantan, D. Chen, K. Sweeney;

Pfizer Inc., New London, USA.

Background and aims: The prediction of long-term clinical efficacy outcomes from early biomarker signals can assist efficient and accelerated drug development by identifying efficacious dose(s), terminating ineffective dosage regimen(s) in a timely manner and comparing new drugs to existing therapies. A model-based meta-analysis was implemented to establish the dose-response profiles for the two key glycaemic efficacy endpoints, glycosylated hemoglobin (HbA_{1c}) and fasting plasma glucose (FPG). Additionally, the link between the HbA_{1c} response, which takes a longer time to reach steady-state, and the FPG steady-state effect, which is achieved at much earlier times, was established.

Materials and methods: A systematic review of literature data sources from 1990 through 2010 of randomized, placebo-controlled clinical trials of anti-diabetic agents from various drug classes (GLP-1 analogues, DPP-4 inhibitors, SGLT-2 inhibitors, thiazolidinediones) administered either as mono- or combination therapies in type 2 diabetes mellitus patients was conducted for this analysis. The dose-response relationships for the change from baseline (CFB) in the steady-state FPG and HbA_{1c} data was described by separate inhibitory E_{max} models with select shared parameters using a nonlinear mixed-effects model. The FPG maximal response and the scale parameter linking the FPG and HbA_{1c} steady-state effects were estimated separately for each drug class. The drug potencies were estimated uniquely for each drug and were shared by the FPG and HbA_{1c} models. The effect of covariates including but not limited to age, disease duration, Asian subjects, body mass index, and combination therapy on the maximal reductions were also investigated.

Results: A total of 595 steady-state observations from 117 trials that met the selection criteria were analyzed by the proposed model, which predicted the dose-response relationships for the two efficacy endpoints reasonably well. The model estimated a maximal decrease in the FPG CFB of -50.2, -20.3, -34.2 and -52.5 mg/dL for the GLP-1 analogues, DPP-4 inhibitors, SGLT-2 inhibitors, and thiazolidinediones respectively. The maximal decrease in the HbA_{1c} CFB for the GLP-1 analogues, DPP-4 inhibitors, SGLT-2 inhibitors, and thiazolidinediones, was estimated to be -1.5, -0.85, -0.71 and -1.4%, respectively. The analysis indicated that subjects with higher baseline FPG and HbA_{1c} values had greater reductions from baseline in their respective responses. On average, the maximum response reductions achievable in Asian subjects were higher as compared to non-Asian diabetic patients. The model predicted that for every 1 mg/dL reduction in the placebo-subtracted FPG response to an anti-diabetic treatment, the decrease in the placebo-subtracted HbA_{1c} endpoint ranged from 0.021% to 0.042% depending on the drug class.

Conclusion: The CFB in FPG and HbA_{1c} endpoints were adequately described by the joint model. Long-term HbA_{1c} responses can be predicted from steady-state FPG measures obtained from abbreviated clinical trials. The scale parameter relating the registration endpoint, HbA_{1c}, with FPG was uniquely identified for the different anti-diabetic drug classes.

Motivating type 1 diabetic patients to learn carbohydrate counting through a cultural/aesthetic experience

A.C. Bianchi¹, A. Morelli², V. Paoletich³, A. Tomasich⁴, A. Chiesa⁵, G. Colucci¹, P. Palumbo¹, G. Torchio¹;

¹Diabetes Center, Clinica San Carlo, Paderno Dugnano, ²Clinical Nutrition, Clinica San Carlo, Paderno Dugnano, ³Art Expert, Milano, ⁴Clinical Psychology, A.O. Salvini, Garbagnate, ⁵Diabetes Association, Milano, Italy.

Background and aims: Carbohydrate (CHO) counting is an important tool that allows diabetic patients greater diet flexibility and improved glycemic control. Yet learning this method is challenging and requires careful application. The purpose of this initiative is to propose a cultural/aesthetic approach to raising awareness and motivating type 1 diabetic patients to learn and apply CHO counting.

Materials and methods: During 3 guided tours at the “Pinacoteca di Brera” in Milan, Italy, type 1 diabetic patients were shown how to calculate the CHO content of food represented in paintings (Figure 1). Out of the 54 participants, 20 had previously received information on CHO counting (experienced group), and 34 had not (naïve group). A suitable route had previously been identified by selecting paintings depicting banquets, still lifes, and last suppers. A professional guide explained the historical and artistic value of the paintings, while a dietitian discussed content of the foods depicted. After the visit, the participants completed an anonymous questionnaire to evaluate the initiative and were asked to estimate the CHO content of 21 food items.

Results: 92% of participants considered the experience very interesting. 90% thought it improved their knowledge. 95%–97% reported that both nutritional and artistic aspects were presented clearly and in sufficient detail. 87% judged the combination of dietary and cultural information positively; no difference was observed between experienced and naïve participants. Importantly, in the naïve group 87.8% agreed to follow a training course on CHO counting, 73% claimed they would be willing to make changes in their diet and 9.7% reported that they would ask their physicians for their own insulin/CHO ratio. All participants would recommend this experience. When tested on the CHO content of 21 food items, correct answers were 34.4% and 49.6% in the naïve and experienced groups, respectively.

Conclusion: Introducing CHO counting in the context of a cultural/aesthetic experience motivated type 1 diabetic patients to learn about this method. The use of visual and verbal communication to convey the necessary dietary concepts appears to be an effective educational tool. The less formal interaction between learners (patients) and teachers (diet and art experts) away from the medical setting reportedly creates a stimulating pedagogical experience. In addition, participation in this initiative in an environment of high cultural prestige may have promoted a dynamic of “narcissistic investment” that motivates patients to engage in learning CHO counting.

Fig 1. The greengrocer: Vincenzo Campi (1536–1591). CHO content of vegetables and fruits.

920

Non-adherence to lifestyle modification and its determinants among type 2 diabetic patients

S.J. Mumu¹, F. Saleh², F. Ara², F. Afnan², L. Ali³;

¹Dept of Epidemiology, ²Dept of Community Nutrition, ³Dept of Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences (BIHS), Dhaka, Bangladesh.

Background and aims: Non-adherence to preventive and therapeutic lifestyle recommendations among patients with diabetes is special challenge in the management of these patients. Understanding the determinants of non-adherence to lifestyle changes can help to plan and implement more intensive interventions to assist patients' long-term task of achieving beneficial lifestyle changes. This study aimed to measure the proportion of non-adherence and its determinants to lifestyle modification (diet and exercise) among a group of Bangladeshi type 2 diabetic patients.

Materials and methods: Under an analytical cross-sectional design 374 type 2 diabetic patients (age >20 years), diagnosed for at least 1 year, were purposively selected from different health care centers operated by the Diabetic Association of Bangladesh (DAB). Data were collected by a pre-tested, interviewer-administered questionnaire. Three-point scale (yes, no, sometimes) were used to assess patient adherence to lifestyle measures (diet and exercise). Patients were considered compliant if patients had adhered to a recommended dietary chart, maintain specific time of food intake and followed advised quantity and quality of food. Exercise were considered adhered if they did exercise >30 min/day. Self management was assessed by self monitoring of blood glucose, foot care and smoking practice. Anthropometric measurements were done by using appropriate tools and all biochemical data were collected from record book.

Results: Of the respondents 58% were females. The mean±SD age was 51 (±11.3) years, about 35% were aged between 40–59 years, 46% had completed high school with mean monthly income US\$ 398 (±375) and 75% lived in urban areas. Mean BMI was 25.7 (±3.6) Kg/m² and about 69% were overweight or obese according to Asian BMI cut-off value. Mean fasting serum glucose was 8.4 (±3.4) mmol/l and about 58% patients' HbA1c level was >7%. About 60% patients attended diabetes education class at least once followed by 24% never attended. Non-adherence rate of diet was 88% and exercise was 25% -overall 89% (95% CI 87.4–91.0) had non-adhered to both diet and exercise. About 32% patients non-adhered to self blood glucose monitoring, 70% to foot care and 6% had smoking habits. The main barriers to adherence to blood glucose monitoring was that they did not believe it is useful (65%) and barriers to do exercise were always being busy (44%) and co-existing diseases (9%). Association was found between non-adherence of diet and residence and nonattendance to diabetes education classes (p<0.05). Age, gender and nonattendance to diabetes education classes were associated with non-adherence to exercise (p<0.05). Binary logistic regression suggests that level of education (p=0.03) and nonattendance to diabetes education classes (p=0.05) are correlates of non-adherence of diet, and gender (p=0.04), family history of diabetes (p=0.04) and age (p=0.04) are correlates to non-adherence to exercise.

Conclusion: Although majority of the patients do not follow dietary and foot care recommendations, the adherence to exercise and blood glucose monitoring is comparatively high. Diabetes education and sociodemographic factors need to be considered to improve adherence to lifestyle modification and self care.

The effects of physical activity in Chinese adults with type 2 diabetes mellitus: a meta-analysis

Q. Shanhu, L. Lili, S. Zilin;

Department of endocrinology, Diabetic institution, Zhongda Hospital, Southeast University, Nanjing, China.

Background and aims: Physical activity is well known as a cornerstone in the treatment of diabetes mellitus. However, the effects of regular physical activity in Chinese adults with Type 2 diabetes mellitus are unclear. Our study aims to conduct a meta-analysis of randomized-controlled trials (RCTs) in order to assess the effects of physical activity on glycemic control, lipids and lipoproteins in Chinese adults with Type 2 diabetes mellitus.

Materials and methods: Search strategy: Chinese databases: VIP (1989 to January 2011), CNKI (1994 to January 2011), CBM (1978 to January 2011),

CPCD (2000 to January 2011), and Papers on Academic Conference of China (2000 to January 2011) were searched. And also the reference lists of all articles collected were checked to ensure that no relevant suitable studies were missed. Selection criteria: All RCTs that evaluated the effects of regular physical activity (duration ≥ 12 weeks) combined with usual treatment versus usual treatment alone in Chinese adults with type 2 diabetes were included. Data collection and analysis: Two authors independently selected trials, assessed trial quality and extracted data. Continuous data were calculated as mean differences (MD). Random-effects model and fixed-effects model were used to perform meta-analysis for with and without heterogeneity respectively.

Results: Only fourteen RCTs were available for pooling involving 1025 participants. Compared with the control, the physical activity intervention significantly improved glycemic control as indicated by a decrease in glycated haemoglobin (HbA_{1c}) levels of 1.34% (-1.34% HbA_{1c}, 95% confidence interval (CI) -1.91 to -0.77; $P < 0.00001$). And there was a reduction in triglycerides (TG) levels and total cholesterol (TC) levels by 0.25mmol/L (-0.25mmol/L, 95% CI -0.36 to -0.15) and 0.74mmol/L (-0.74mmol/L, 95% CI -1.05 to -0.43) respectively with physical activity intervention. Also high-density lipoprotein cholesterol (HDL-C) levels increased by 0.12mmol/L (0.12mmol/L, 95% CI 0.08 to 0.16) and low-density lipoprotein cholesterol (LDL-C) levels decreased by 0.61mmol/L (-0.61mmol/L, 95% CI -0.82 to -0.40).

Conclusion: Although our overall results suggest that physical activity decreases HbA_{1c}, TG, TC and LDL-C and increases HDL-C in Chinese adults with Type 2 diabetes, additional randomized-controlled trials are needed on these topics.

922

Improving health numeracy: utilizing objective parameters to improve shared decision making for insulin initiation

N. Agrawal¹, S.K. Kalra², B. Kalra², S. Agrawal¹;

¹DOTC, Gwalior, ²Bharti Hospital, Karnal, India.

Background and aims: Health numeracy is the ability to understand, and act upon quantitative data, in an appropriate and effective manner. Health numeracy is distinct from health literacy. Health numeracy is associated with better self-management. This study was performed at two endocrine centres in north India, to assess and improve the health numeracy of patients with type 2 diabetes, with an aim to improving the quality of shared decision making (SDM).

Materials and methods: A three months long campaign was begun to explain the meaning of HbA_{1c}, vibration perception threshold and mean plasma glucose to 1000 patients presenting with T2DM in the OPD. This study was carried out by laboratory technologists, by means of semi-structured training, at each OPD visit.

Results: At baseline, 24.5, 11.8 and 45.0 % of patients understood the meaning of HbA_{1c}, mean vibration perception threshold (VPT) and mean plasma glucose (MPG) respectively. At three months, these proportions had increased to 56.6, 90.0 and 67.3 % respectively. During these three months, 351 patients were initiated on various regimes of insulin, of which 250 consented to fill a pre structured questionnaire. 60.0 % of them felt that understanding their HbA_{1c} value had played a major role in motivating them to begin insulin. Similar response was given by 80.0 % for mean VPT and 100 % for MPG.

Conclusion: This paper highlights the efficacy of improving health numeracy as a means of enhancing shared decision making, and facilitating insulin initiation in type 2 diabetes. It reveals the higher importance of mean plasma glucose values, rather than HbA_{1c} and mean VPT in motivating patients to accept insulin.

923

Continued smoking exacerbates but cessation ameliorates progression of early type 2 diabetic complications

V. Voulgaris, C. Voulgaris, P. Dilaveris, C. Tsioufis, N. Katsilambros, C. Stefanadis, N. Tentolouris; Athens University Medical School, Greece.

Background and aims: Diabetes is considered among the target groups for smoking cessation treatment, due to the increased health risks associated with smoking. The effect of 4-year smoking cessation upon type 2 diabetes (T2DM) diagnosis was assessed in this study.

Materials and methods: From 500 smokers, 200 (100 men/ 100 women: age 56.4 \pm 7.8 years) agreed to participate and were educated to smoking cessa-

tion, diet and exercise. Pharmacological interventions, smoking duration, daily frequency, and cumulative smoking exposure did not differ between the studied groups. Demographic, clinical and biochemical parameters were obtained at baseline and at 12-months follow-up. Peripheral vascular disease (PVD) was diagnosed ultrasonographically and peripheral neuropathy (PN) on neuropathy symptom and disability score. Retinopathy was diagnosed by direct funduscopy. At the end of the study, smoking status was confirmed by an expired CO level of <10 ppm.

Results: A total of 120 subjects (24%) quit smoking. Smoking cessation was accompanied by an increase in BMI ($P=0.05$), in physical activity ($P=0.01$), better glycemic ($P=0.04$), blood pressure ($P=0.03$) and lipids control ($P=0.02$) compared to smoking continuance. Smoking cessation ameliorated prevalence of PVD (8.2% vs. 7.5%, $P=0.03$), PN (15% vs. 10.9%, $P=0.04$), and retinopathy (4.3% vs. 3.9, $P=0.04$) compared with smoking continuation. Microalbuminuria was reduced at 4-year to 12.5% of the subjects who continued smoking and to 82.6% of those who quit smoking ($P < 0.001$). Multivariate logistic regression analysis demonstrated that independent predictors of the reduction in microvascular complications were amelioration of insulin-resistance [HR, 95%CI: 1.18 (1.08-1.23)], blood pressure [1.03 (1.01-1.06)], glycemic control [1.10 (1.04-1.13)] and lipids profile [1.12 (1.14-1.26)]. From treatment and lifestyle interventions, smoking cessation had the highest contribution to the reduction of microvascular complications [1.20 (1.18-1.23)]. **Conclusion:** Smoking cessation in newly-diagnosed T2DM improves insulin-resistance, glycemic control, blood pressure, and lipids profile and reduces microvascular complications. Stricter counselling about the importance of quitting smoking is necessary upon T2DM diagnosis.

924

What do patients need? The development of a patient-centred health educational model for patient education

U. Møller Hansen, G. Englund, I. Willaing;

Patient Education Research, Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Patient education is a crucial element in the treatment and care of patients with type 2 diabetes and other chronic illness. However, a majority of models for patient education is based on a professional or theoretical understanding of patients' needs for learning rather than on a patient perspective. Patient education programmes thereby risk neglecting themes and issues that are important to the patients. This might limit the effect of the patient education. The aim of the present study was to explore the educational needs from a patient perspective in order to develop a model for patient education based on needs and perspectives as defined by patients.

Materials and methods: Guided by an Action Research approach we explored the perceptions, views and experiences of patient education among patients with type 2 diabetes, COLD and heart disease, eligible to or participating in group-based patient education in four Danish municipalities. Four highly interactive workshops were conducted with 25 adult patients in August and September 2010. At the workshops customised tools were used in order to generate a dialogue about specific themes. The workshops were video recorded and the analysis was based on the constant comparative method. The insights from the workshops were presented to a group of 25 health care professionals who were then asked to translate the insights into patients' needs for patient education. The identified needs were categorised and grouped repeatedly until four basic needs or focal points for patient education emerged.

Results: The patient-based model for patient education is formed by the following four focal points:

1. Entirety is about ensuring the link to the entire life of the patient:

- Connecting the past, present and future
- Seeing the person instead of just a disease
- Ensuring a main thread in the teaching

"It's about what your life is and what keeps you going. You cannot talk illness all the time. That will make you ill" quote from a patient

2. Clarity is about creating clarity about challenges and possibilities:

- Encouraging the articulation of imbalances
- Communicating relevant knowledge
- Using visual and tangible methods

"The most important was that I realized that I cannot deal with this myself. I need help and support" quote from a patient

3. Timing is about choosing the right thing at the right time:

- Identifying the individual's own process of change
- Creating time and space for anchoring
- Pinpointing optimal moments and content

"I would like to have more time to unplanned discussions and to talk with the others" quote from a patient (about the patient education process)

4. Connectedness is about supporting the need to be social and connected:

- Strengthening group dynamics
- Encouraging the sharing of experiences
- Creating a setting that enhances confidence
- Supporting relations to surroundings

"It is really good to talk to the person sitting next to you and to the group. It gives inspiration and ideas" quote from a patient

Conclusion: In order to meet the needs of patients the developed model suggests that four focal points are central. The model can be used as a planning tool for patient education programmes as well as an analytical tool for the evaluation and quality assurance of the delivered education. Future implementation and effect studies are needed to assess the effect of the model and to assure and determine the quality of this patient-centred approach.

925

Low physical activity reduces mortality in community dwelling older adults with diabetes but not in those without diabetes

S. Akter^{1,2}, Y. Zhang³, I.B. Aban⁴, X. Sui⁵, K. Karatzidou⁶, C. Adamopoulos⁶, P. Deedwania⁷, S.N. Blair⁸, L. Ali^{2,1}, A. Ahmed^{8,9},

¹Biochemistry and Cell Biology, BIRDEM, Dhaka, ²Biochemistry and Cell Biology, Bangladesh Institute of Health Sciences, Dhaka, Bangladesh, ³Medicine, University of Alabama at Birmingham, Birmingham, USA, ⁴Biostatistics, University of Alabama at Birmingham, Birmingham, USA, ⁵Exercise Science, University of South Carolina, Columbia, USA, ⁶Medicine, Papageorgiou General Hospital, Thessaloniki, Greece, ⁷Medicine (Cardiology), Veterans Affairs Central California Health Care System and University of California, San Francisco, Fresno, USA, ⁸Medicine (Geriatrics and Cardiology) and Epidemiology, University of Alabama at Birmingham, USA, ⁹Medicine (Geriatrics), Veterans Affairs Medical Center, Birmingham, USA.

Background and aims: Most physical activity (PA) guidelines recommend at least 500 MET-minutes/week of PA for adults to achieve substantial health benefits. However, PA level may be reduced in older adults in general, and in older adults with serious comorbidities such as diabetes mellitus (DM) in particular. We used the public-use copy of the Cardiovascular Health Study (CHS) data obtained from the National Heart, Lung, and Blood Institute (NHLBI) to examine associations of various levels of PA in community-dwelling older adults with and without DM.

Methods: Of 5775 CHS participants with data on baseline leisure-time kilocalories of energy expended/week, 941 (16%) had DM. Participants were categorized into 4 PA groups (based on MET-minutes/week): Inactive (0 MET-minutes/week; n=539); low PA (0 to 499 MET-minutes/week; n=1555); medium PA (500 to 999 MET-minutes/week; n=1129); and high PA (≥ 1000 MET-minutes/week; n=2552). Cox-regression models were used to examine the relationships between PA categories and all-cause mortality during 13 years of follow-up, separately among those with and without DM.

Results: Patients (n=5775) had a mean (\pm SD) age of 73 (± 6) years, 58% were women, and 16% were African Americans. Compared with inactive older adults, medium and high PA was associated with reduced mortality regardless of DM (Table). However, only in those with DM, but not in those without DM (p for interaction, 0.002), a low PA was associated with reduced mortality (Table).

Table. Physical activity levels and mortality in older adults with or without diabetes mellitus

	Physical activity	MET-minutes per week	Mortality, %	Unadjusted hazard ratio (95% CI)	Adjusted* hazard ratio (95% CI)
No diabetes (n=4834)	Inactive	0	57%	1 (Reference)	1 (Reference)
	Low	0-499	48%	0.77 (0.66-0.89); p<0.001	1.03 (0.88-1.20); p=0.317
	Medium	500-999	41%	0.60 (0.51-0.71); p<0.001	0.85 (0.72-0.998); p=0.058
	High	≥ 1000	38%	0.51 (0.44-0.58); p<0.001	0.72 (0.62-0.84); p<0.001
Diabetes (n=941)	Inactive	0	73%	1 (Reference)	1 (Reference)
	Low	0-499	59%	0.67 (0.52-0.86); p=0.002	0.70 (0.54-0.91); p=0.007
	Medium	500-999	62%	0.67 (0.51-0.89); p=0.005	0.75 (0.56-1.00); p=0.051
	High	≥ 1000	57%	0.57 (0.45-0.74); p<0.001	0.65 (0.50-0.85); p=0.002

* Adjusted for age, gender, race, pack-years of smoking, weekly alcohol consumption, depression score, mini-mental status score, body mass index, hypertension, coronary artery disease, heart failure, atrial fibrillation, stroke, serum creatinine, left ventricular hypertrophy by electrocardiography, and left ventricular systolic dysfunction by echocardiography

Conclusion: Recommended levels of medium and high PA is associated with improved survival in older adults with and without DM. However, older adults with DM also benefit from lower levels of PA, in whom the mortality benefit does not appear to increase with higher levels of PA.

Seasonal variation of hypoglycaemic episodes in a single university hospital in Korea

O. Ryu¹, M.-G. Choi¹, S. Yu², H. Yoo³, J. Kang³, C. Kim³, S. Lee³, S. Ihm³, J. Yu², E. Hong², J. Park², D. Kim²;

¹Division of endocrinology and metabolism, department of internal of medicine, Hallym University College of Medicine, Chuncheon, ²Division of endocrinology and metabolism, department of internal of medicine, Hallym University College of Medicine, Seoul, ³division of endocrinology and metabolism, department of internal of medicine, Hallym University College of Medicine, Anyang, Republic of Korea.

Background and aims: Hypoglycemia is a leading limiting factor for the glycemic management in diabetic patients. The main cause of hypoglycemia is insulin excess relative to carbohydrate intake. We investigated the risk factors and seasonal variation of hypoglycemic episodes in diabetic patients visiting emergency center.

Materials and methods: We selected the patients who visited emergency center in Chuncheon Sacred Heart Hospital, Hallym University for the management of hypoglycemia from January 2008 to December 2010. Hypoglycemia was defined by the symptom and serum glucose < 70 mg/dL. We excluded the patients who had no history of diabetes. We reviewed medical records in terms of age, visiting date, HbA1c (%), cause of hypoglycemia (change of food intake and physical activity), medications (sulfonylurea, glinide, or insulin), hemoglobin (g/dL), albumin (g/dL), creatinine clearance (estimated GFR by the MDRD equation).

Results: During the study period, there were 196 hypoglycemic episodes in 168 diabetic patients. The mean age was 70.3 ± 11.2 years (34-91). The level of mean glucose was 36.2 ± 12.5 mg/dL. The proportion of HbA1c $< 6.5\%$ was 50.5%. The hypoglycemic episodes was most common in summer season (June to August: 34.7%) and least common in fall (September to November: 17.9%). The main cause of hypoglycemia was decreased food intake (51%). Most patients had gastrointestinal symptoms, such as nausea, vomiting, or diarrhea. Sulfonylurea was taken by 52.6% of patients. The proportion of chronic renal failure (eGFR < 60 mL/min/1.73 m²) was 55.6%, anemia was 64.1%, and low albumin (< 4 g/dL) was 53.1%.

Conclusion: The risk factors of hypoglycemic episodes in this study were old age, good glycemic control, comorbidity (chronic renal failure, anemia, and malnutrition), summer season, and decreased food intake. The hot and wet weather in the summer in Korea might be decreased food intake, especially in old, comorbid diabetic patients. The decreased food intake in summer season should be considered for preventing hypoglycemia, especially in old, comorbid diabetic patients.

927

Patients with type 2 diabetes prefer education based on participation and development of competences over information

I. Willaig¹, M. Schiøtz¹, M. Bøgelund², T.P. Almdal³, B.B. Jensen¹;

¹Steno Health Promotion Center, Steno Diabetes Center, Gentofte, ²Incentive Partners, Birkerød, ³Steno Patient Care Clinic, Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Little is known about patient preferences for diabetes patient education. The objectives of this study were to determine the preferences of patients with type 2 diabetes for format and contents of patient education and support. We investigated how patients value information, participation and competence development, and involvement of the social network. Patients were also asked to value group based versus individual education.

Materials and methods: A questionnaire was developed including questions on socio demographic data, height and weight, perceived care, psycho-social problems, social network, self-management behaviours and HbA1c-level as well as choice games concerning patients' preferences for patient education and support. Questionnaires were sent to patients with type 2 diabetes from two different populations: 1) a population of patients from a specialist diabetes clinic (n=1081, response rate 54%) and 2) a population of type

2 diabetes patients derived from a web panel consisting of a representative sample of the Danish population ($n=1461$). In total a population of 2542. The data collection took place September to November 2010. The choice game answers were analysed using the conditional logit model. Willingness To Pay for the attribute levels was calculated by dividing the estimated coefficients, β , for each attribute by the coefficient of payment. For deriving the confidence intervals for the Willingness To Pay results, 10,000 iterations were carried out by bootstrapping. Analyses were stratified for age, gender, educational attainment and other subgroups. A 5% level of significance was used. **Results:** All included attributes were significant predictors of choice ($p<0.01$) and all parameters had a positive value. Patients consistently valued acquiring competency in the included topics more than receiving information about them except for psychological problems. The difference in valuation between becoming competent and acquiring information was largest for living a fulfilling life with diabetes (willingness to pay was 92% higher for competency). Becoming able to adjust diets and exercise habits and becoming able to prevent complications were valued 35% and 46% higher, respectively, than only being informed about these topics. Patients valued support to ask questions to health care professionals nearly twice as high (€212) as receiving support to find networks (€117). Patients preferred to be involved in the planning of their diabetes care (€130) compared to planning their diabetes care alone. Patients were willing to pay €199 to be educated individually compared to education in a group of 12. Patients valued individually tailored content as worth €146 compared to prescheduled content. The ranking of the attributes and levels were similar for subgroups. Women generally had a higher valuation of attributes. Patients <60 years had a higher Willingness To Pay for all attributes and levels than older patients. Patients with HbA1c <7% exhibited higher Willingness To Pay for all attributes and levels. **Conclusion:** Patients with type 2 diabetes significantly value participation in patient education, development of competencies for prevention of complications and support from the social network in disease management. Patients prefer an individually targeted approach.

by educators played a significant role to increase awareness ($\%$, 68.8 ± 10.6 vs 57.0 ± 12.8 ; $p<0.0001$) in type 2 diabetic subjects. The awareness score was found significantly lower in women than in men ($\%$, 70.6 ± 10.9 vs 66.6 ± 10.8 ; $p<0.0001$). About 76% subjects believed that taking OHA or diet for controlling diabetes is comparatively risk-free for developing complications than those who took insulin. About 47% were aware of the importance of maintaining good glycemic control and 66% considered this as a very difficult task. **Conclusion:** Bangladeshi type 2 DM subjects are moderately aware about diabetes and risk factors of NCDs. These subjects have poor level of awareness regarding risk factors of diabetes, cause of dyslipidemia and obesity, normal level of lipid profile and blood pressure. Sex, family history, acquisition of information through educational tools are the most important determinants of awareness.

928

Awareness among Bangladeshi type 2 diabetic subjects regarding diabetes and risk factors of non-communicable diseases

F. Ara¹, F. Saleh¹, S.J. Mumu², F. Afnan¹, L. Ali³

¹Dept of Community Nutrition, ²Dept of Epidemiology, ³Dept of Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences (BIHS), Dhaka, Bangladesh.

Background and aims: Awareness among type 2 diabetic subjects is a major determinant for the prevention of diabetes and its complications as well as related risk factors of non-communicable diseases (NCDs). This is also required to design strategy for awareness campaign. The present study aimed to assess the awareness of diabetes and the risk factors of NCDs among Bangladeshi type 2 diabetes subjects.

Materials and methods: A total of 500 subjects (43% male and 57% female; age 52 ± 11 years, mean \pm SD) were selected from different health care centers in Bangladesh under a cross-sectional design. A pre-structured interviewer administered questionnaire was used for collecting data. Questionnaire was divided into 5 main sections, namely general definition of diabetes, dyslipidemia, hypertension and obesity; risk factors of NCDs and complications, treatment and management of the diabetes. On the basis of predefined scoring the levels of awareness score was categorized as good (>75%), moderate (50–75%) and unacceptable (<50%). According to WHO (2006), BMI was classified as underweight (<18.5 kg/m²), normal (18.5–25 kg/m²), over weight (25–30 kg/m²) and obese (>30 kg/m²).

Results: The proportion of good, moderate and unacceptable level of awareness among the subjects were 31%, 62% and 7% respectively. Majority (89%) of the participants had correct understanding regarding basic definition of diabetes though 77% among them did not know about the risk factors of DM and 19% thought excess sugar intake is a major cause for developing diabetes. Only 29% were aware about the consequences of uncontrolled diabetes. Most of the participants (99%) did not have any idea about the risk factors of NCDs such as dyslipidemia, obesity and also did not know the cut-off values of BMI (100%), triglycerides (95%) and total cholesterol (82%). However, 94% of the subjects knew about hypertension and the cut-off value of blood pressure. Only 12% correctly answered regarding the causes of hypertension. Subjects (33.5%) with positive family history of DM were more aware regarding diabetes than those (26.8%) without such family history. Regarding NCDs risk factors, only 16.1% subjects with history of NCDs had good awareness. Acquisition of information through educational tools and group discussion

Community health workers effectiveness in diabetes education

C.F. Souza, M.B. Dalzochio, A.T.N. Zucatti, R. De Nale, M.T. Almeida, J.L. Gross, C.B. Leitão;
Endocrinology, Hospital de Clínicas de Porto Alegre, Brazil.

Background: Community health workers (CHWs) are members of the community hired by the government to carry out functions related to health promotion and prevention within their communities. The use of CHW has been identified as one strategy to address the growing shortage of health workers, particularly in low-income countries. In Brazil, CHW are widely used to provide education and care for patients for a broad range of health issues, including diabetes mellitus (DM). However, few CHW are trained for diabetes education and little is known about the effectiveness of their interventions. The aim of the study is to evaluate the effectiveness of a diabetes education program delivered to CHW in improving the metabolic control of patients with type 2 diabetes.

Materials and methods: A randomized controlled trial was conducted in a primary care unit. Eight CHWs, providing care for 118 patients, were randomized in two groups to receive a one-month (four sessions, two hours each) diabetes education program (intervention group, patients $n=62$) or an education course in other health issues (control group, patients $n=56$). Each CHW were then responsible for transmitting the acquired knowledge to the patients from their respective work areas. The primary outcome was change in A1C, and the secondary outcomes were the effect in weight, blood pressure, lipids and acquired learning 4-month after the intervention.

Results: Participants mean age was 61 ± 11 years with median diabetes duration of 6 (IQR= 3 - 5) years, 35% were men and 62% were whites. Included subjects had a mean of 5.0 ± 3.5 years of formal literacy and 41.6% had a mean family income less than US\$ 450 per month. Mean BMI was 31 ± 6 kg/m² and mean A1c was $9.0 \pm 2.5\%$ (no differences between groups regarding these variables at baseline). No change was observed in patient's DM education scores (intervention: 15 ± 5.2 vs 15 ± 6.0 and control group: 14 ± 4.7 vs 15 ± 5.5 , $p=0.43$). A1c levels were reduced in both groups (intervention 9.1 ± 2.2 vs 7.5% and control 9.2 ± 2.1 vs $7.9 \pm 2.1\%$, $p<0.001$), but no statistically significant differences were observed between groups ($p=0.22$).

Conclusion: A diabetes education program centered in patient's self-management delivered for CHW did not improve the glycemic control of patients with type 2 diabetes after a 4-month period. Other DM educational strategies should be studied in order to improved diabetes control in the public health scenario.

A diabetes specialist care inpatient team as diabetes educators

A.P. Brooks, J. Chong, S. Grainger-Allen, M. McDonald;
Diabetes Specialist Clinic, Royal Hampshire County Hospital, Winchester, UK.

Background and aims: To improve the education of patients with diabetes and health care professionals in a general hospital through the work of a diabetes specialist care inpatient team.

Materials and methods: A diabetes specialist care inpatient team was set up in 2006 in a 400 bed general hospital consisting of Consultant Physician, Diabetes Nurse Specialist and doctors in training. Each week the team will visit every medical and surgical ward on two days, seeing all the inpatients with diabetes either as primary diagnosis or comorbidity, and liaise with ward medical and nursing staff (HCPs).

Results: In the 6 months January to June 2008 and 2009 respectively: 367 and 397 patients were seen; 851 and 992 visits were made; 620 and 300 interventions were for direct patient advice, and 49 and 297 HCP advice; and 296 and 347 treatment changes were made. In the 2009 National Diabetes Inpatient Audit (Diabetes UK) the hospital had only 5% (insulin) prescription errors (v 19% nationally, $p<0.05$, t test) and 3% (patient) management errors (v 14%, $p<0.05$), with 100% appropriate blood glucose monitoring (v 86%). Mean number of "good diabetes days" was 5.5 v 4.2 nationally ($p<0.05$) and 83% patients (v 73%) reported a positive experience of diabetes care.

Conclusion: A diabetes specialist care inpatient team improves the quality of care and education of patients and health care professionals as evidenced by: the low frequency of insulin prescribing and management errors; the 100% appropriate blood glucose testing; and more "good diabetes days" and frequency of visits to patients with a positive outcome.

931

The mode of diabetes education is a determinant of glucose control in a Chinese diabetic patient cohort

Y. Dong^{1,2}, L. Zhang^{1,2}, M. Xu¹, N. Wang¹;

¹Qingdao Endocrine & Diabetes Hospital, ²Weifang Medical University, China.

Background and aims: Diabetes education plays an important role in patient management and metabolic control. The aim of this study was to investigate the mode of diabetes education in relation to glucose control in a Chinese cohort of diabetic patients.

Materials and methods: This retrospective study was based on a diabetes education programme (once a week) initiated in 2003 that included 156 diabetic patients (17 type 1 and 139 type 2, mean age 50 ± 5 years) from Qingdao, China. A conventional education mode was given in the way of classroom lecture to all patients from 2003 to 2006. Since 2007, personalized face-to-face group sessions (4 patients per group) was introduced due to the withdrawal from conventional education mode. The patients were classified into group 1 (conventional) and group 2 (shifted from conventional to personalized mode) during 8-year follow-up. General linear model was used to compare the HbA1c levels between groups adjusting for age, medication treatment and baseline glucose levels.

Results: There was 79 in group 1 and 77 in group 2 in 2003. 75 withdrew from group 1 and 29 withdrew from group 2 by the end of 2010. Mean HbA1c significantly decreased in both groups in 2004 ($p<0.05$) and tended to increase in 2005 and 2006. Patients in group 2 had significantly lower HbA1c in 2007 (6.5% vs. 7.1%, $p<0.05$), 2008 (6.7% vs. 7.3%, $p<0.05$) and 2009 (6.9% vs. 7.2%, $p=0.06$). We were not able to analyse the data in 2010 due to a high withdrawal rate from group 1 (Figure 1).

Conclusion: Conventional education mode is not enough for long-term ideal glucose control. Regular improvement of education mode might be an important way to enhance patients' interests of participating in an educational programme and improve glucose control.

932

Beyond the "self" in diabetes care: what are the tools and what are the effects?

N. Schwennesen, L.E. Joensen;

Steno Health Promotion Center, Gentofte, Denmark.

Background and aims: Living with diabetes has serious implications for everyday life and social relationships, especially in relation to social activities such as diet, exercise and clinical care. Programmes of patient education are dominated by an individualistic approach to diabetes management, emphasising knowledge, individual motivation, self-efficacy and choice. While such foci are relevant for engaging individuals in self-care, it is important to supplement such foci with approaches relating to the social formation of every-

day life and social relationships outside the formal healthcare setting in order to support long term self-care. This review aims at furthering the knowledge on how to effectively design and implement interventions targeting adult diabetic patients, that involves the social context of the diabetes patient.

Materials and methods: A systematic search was conducted in relevant databases identifying reviews published between 2000 - February 2011. Specific keywords were selected with a main focus on terms related to; diabetes, intervention and social context. 518 results were found and 19 reviews were selected after systematically reading through abstracts and titles. Inclusion criteria were: Reviews over intervention studies targeting adult diabetic patients involving other subjects than the patient or health care professional.

Results: Two kinds of interventions were identified 1) Family interventions directed at the existing social network of the diabetic patient 2) Interventions directed at peers, seeking to support through a created social network. Under both kinds of interventions we have an additional focus on studies targeting specific cultural and marginalised groups that takes social context as a basic condition of the intervention. Only two intervention studies directed at family members can be identified. These studies suggest that family interventions may be supportive as well as constraining on self-care behaviour (diet) and that the social dynamic in the family plays a significant role. Moreover, they suggest that gender makes a difference in perceived family support. There is a strong immediate positive effect on face-to-face interventions involving peers on glycemic control, quality of life and self-efficacy. There are promising preliminary results of use of peers as mentors and community health workers on clinical, psychological and behaviour outcome and are especially relevant for interventions targeting minority groups. No intervention studies on the use of peers in telephone interventions have been conducted, but a pilot study found high levels of participation and satisfaction. Adding peer support components to internet based interventions can increase their effectiveness in terms of weight loss, coping and self-efficacy. We need more knowledge about recruitment, education and support of peers.

Conclusion: This review supports the hypothesis that involving the patients' social context in interventions affects patient self-care. The review shows promising preliminary results, but more research is needed on designing, implementing and evaluating different models of interventions, especially family interventions for adult diabetic patients and the use of peers outside the clinic. Also we need more knowledge about how to create more flexible forms of interventions, where elements can be put together and adapted to family situation of the individual, life circumstances and culture.

933

Effects of a newly developed education programme (MEDIAS 2 ICT) for patients with type 2 diabetes with intensive insulin therapy: results of a randomised prospective trial

N. Hermanns, B. Kulzer, B. Maier, M. Mahr, T. Haak;
Research Institute of Diabetes Academy Mergentheim (FIDAM), Bad Mergentheim, Germany.

Background and aims: Introduction: In a randomized, multi-centre trial, the effect of an education programme (MEDIAS ICT) involving intensive insulin treatment for type 2 diabetic patients was compared with an established education programme as an active comparator condition (ACC). Participants of the experimental group received a group training using MEDIAS 2 ICT which comprises 10 lessons. The participants of the control group (ACC) participated in the previously established "Education programme for type 2 diabetic patients injecting prandial insulin" and the "hypertension education programme". But programmes together had duration of 10 lessons, which also consisted of 10 lessons.

Materials and methods: A total of 185 type 2 diabetic patients from 18 different study centres were randomized to either MEDIAS ICT or ACC. It was expected that MEDIAS 2 ICT would be at least as effective as the ACC with regard to improvement of HbA1c values of the participants (non inferiority hypothesis). Secondary outcome variables were the perceived burden of diabetic illness, knowledge about diabetes, Quality of Life, self management behaviour as well as the amount of lipids and blood pressure

Results: The mean HbA1c decrease was 0.37 % (from $8.2 \pm 1.1\%$ to $7.8 \pm 1.5\%$) in the ACC and 0.63 % (from $8.5 \pm 1.6\%$ to $7.9 \pm 1.2\%$) in MEDIAS ICT. The mean difference between both groups was -0.26 in favour of MEDIAS ICT, with a 95%CI ranging from -0.64 percentage points to 0.12 percentage points; this result was within the predefined limit of 0.4 percentage points for non-inferiority. Diabetes-related distress was significantly more reduced in MEDIAS ICT (-3.4 ± 7.1) than in ACC (-0.4 ± 9.0 ; $p = .031$). Both groups increased their diabetes knowledge significantly. MEDIAS ICT participants showed

a significant within group difference regarding self-care behaviour and the physical composite score of the Short Form Health Survey (SF-12), whereas ACC participants did not, but between group differences were not significant. There was no specific effect of either intervention on lipids or blood pressure.

Conclusion: MEDIAS ICT is as effective in lowering HbA1c as previously established education programmes. In addition, MEDIAS ICT has proven its efficacy regarding the improvement of diabetes knowledge, health-related quality of life, and self-care behaviour. Participants of MEDIAS ICT were able to reduce diabetes-related distress to a significantly greater extent than patients who took part in more-established traditional education programmes focusing on diabetes knowledge and adherence. Blood pressure and lipids were at an adequate level at the start of the study which did not leave much room for improvement. In sum, MEDIAS 2 ICT is an effective alternative to already established programmes used for training type 2 diabetes patients in the need for an intensified insulin therapy. We conclude that MEDIAS ICT, which involves intensive insulin treatment, provides an alternative to previously established education programmes

Clinical Trial Registration Number: NCT00901992

Care for the elderly with diabetes

S. Hryhorian, A. Ramalho, L. Roque, R. Louro, B. Castelo, G. Rodrigues, L. Geada, C. Cruz, L. Arez;
Departamento de Medicina, Núcleo de Diabetes, Centro Hospitalar do Barlavento Algarvio, Portimão, Portugal.

Background and aims: Education is crucial for the control of chronic diseases. Being recognized the need for training of caregivers of people with diabetes. The project "Care for the Elderly with Diabetes" was developed to solve this problem with the aim to improve the trainees' skills in providing care to the elderly with diabetes.

Materials and methods: We conducted six training sessions, between 30/04 and 25/06/2010 for a total of 86 trainees. The topics covered were diabetes treatment, diet, exercise, metabolic control, treatment of hypoglycemia and care for the feet. To assess sensitivity to change, a questionnaire was administered to all subjects before, at the end and after training and subsequently analyzed the mean differences in knowledge, using t test for paired samples.

Results: We included 86 trainees, all of female gender, 90.7% of Portuguese nationality, with an average age of 42.7 years (SD 10.6), 87.2% were formal caregivers. The average score of the questionnaire before training was 75.4%, with items from the rotation of the local administration of insulin (43.0%), foot care (55.0%) and blood glucose monitoring (57.0%), those where the students had more difficulty. The evaluation at the end of training was 95.1% and after 30 days 93.9%. There is statistical evidence that the training increased the knowledge of the trainees in the area of diabetes ($p < 0.001$).

Conclusion: We found that the knowledge of students increased significantly in the area of diabetes. The realization of these training courses may lead to an improvement of care for elderly dependents.

935

The health educational juggler: exploring needs for competences in health care professionals

J. Voigt, G. Englund, U. Møller Hansen;
Patient Education Research, Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Patient education is a crucial element in treatment and care of patients with Type 2 diabetes and other chronic illness. Because of lack of significant effect patient education needs new approaches. The literature indicates empowerment and participation are promising new approaches. However, working with participatory methods is not part of the curriculum and experience among health care professionals like nurses, dieticians, physiotherapists etc. Health care professionals need to be capable of using participatory and empowerment based methods. The need for this competence development was explored in order to design a model for competence development among health care professionals with the aim of providing participatory patient education for patients with chronic illness.

Materials and methods: Action research was used and qualitative data was collected in three workshops with 25 health care professionals (physiotherapists, nurses, occupational therapist, and dieticians) from patient educational settings in four Danish municipalities. The workshops were conducted from

November – January 2011. Data was collected through visual materials and group discussions focused on patient needs. Observation of patient education, written reflections and Story Dialogues were performed and videotapes, quotes and field notes were obtained. The analyses had a Grounded Theory approach; data was analysed by three researchers in three steps: 1) open coding, 2) thematic categorization, and 3) selective and theoretical coding including health educational theories on mediating roles, the transtheoretical model of change, comfort zones and facilitation. This led to the configuration of the main category and roles that finally generated the competence model.

Results: A competence model with four health educational roles was generated: a) the embracer (the emphatic educator), 2) the facilitator (the facilitating educator), 3) the translator (the professional educator), and 4) the initiator (the inspiring educator). These four health educational roles focus on a necessary juggling between roles which is crucial for managing genuine patient involvement that leads to empowerment. The empirical findings pointed out the embracer as the dominating strength and the facilitator, the initiator and the translator as dominating weaknesses among the health care professionals. To enhance patient education as a Health Educational Juggler health care professionals need development of competences in juggling with these roles. **Conclusion:** The study indicates that health care professionals conducting participatory patient education need to develop specific competences to be able to juggle with the professional roles in performing participatory patient education. Furthermore they need to take in new practices, reflecting on individual strengths and weaknesses as a part of the ongoing competence development. The model “The Health Educational Juggler” can be used as an analytical tool in the planning phase of participatory patient education, and as a model for competence development for health care professionals.

936

A 12-month audit of the intensive weight management programme run at a large teaching hospital's diabetes centre

K. Hill, C. Brame, A. Ahmad;

Diabetes centre, The Royal Liverpool and Broadgreen University Hospitals nhs trust, UK.

Background and aims: NICE recommends health care professionals should make preventing and managing obesity a priority. We have set up a multidisciplinary intensive weight management service which includes setting weight loss goals, dietary advice, medication review and physical activity. The aim of the audit was to investigate if patients attending the program show a reduction to their weight, HbA1c and body mass index (BMI).

Materials and methods: A retrospective audit of all patients who attended the weight management program between January 2009 and July 2010 was performed comparing the data at baseline and then again at 12 months. The data was obtained from the trust diabetes database. The intensive weight management service consists of multidisciplinary consultant lead appointments where patients were enrolled into the program and their management plan agreed. This was followed by joint monthly review by DSN and Dietitian and further consultant review at 6 months. In addition patients were referred to the local Exercise for Health Program.

Results: Data was analysed using a paired t-test. Significance is $p < 0.05$. Significant improvements were seen in weight 122.45kg (SEM± 2.96) to 102.40kg (SEM±3.08) $p=0.001$ and BMI 42.81kg/m³ (SEM± 1.00) to 37.88kg/m³ (SEM±0.94) $p=0.001$. No significant changes were found in HbA1c 8.05%(SEM±0.27) to 7.59%(SEM± 0.30) $P=0.297$.

Conclusion: The audit showed that patients who attended this intensive weight management program achieved significant improvements in both weight and BMI. Although the HbA1c improved this did not achieve significance, this may possibly be explained because some patients who had their insulin discontinued when commencing incretin mimetic therapy showed a deterioration in HbA1c levels.

937

Persistence of initial treatment with metformin and/or sulphonylureas in patients with type 2 diabetes

G. Jermendy¹, I. Wittmann², L. Nagy³, Z. Kiss³, G. Rokszin⁴, Z. Abonyi-Tóth⁴, L. Katona⁵, G. Paragh⁶, I. Karádi⁷, B. Merkely⁸;

¹3rd Medical Department, Bajcsy-Zsilinszky Hospital, Budapest, ²2nd Medical Department, Medical University, Pécs, ³MSD Hungary Ltd, Budapest, ⁴RxTarget Company Ltd, Szolnok, ⁵Society of Clinical Biostatistics, Budapest, ⁶1st Department of Internal Medicine, University of Debrecen, ⁷3rd Department of Internal Medicine, Semmelweis University, Budapest, ⁸Heart Center, Semmelweis University, Budapest, Hungary.

Background and aims: Adequate persistence of oral antidiabetic treatment is highly important to achieve proper glycaemic control in patients with type 2 diabetes. The aim of the study was to evaluate the persistence of initial treatment with metformin and/or sulphonylureas in patients with type 2 diabetes. **Materials and methods:** Using the database of the Hungarian National Health Insurance Fund Administration, the persistence of initial treatment with metformin and/or sulphonylureas was evaluated between 2007–2009 in a large population ($n = 256,384$) and the results were compared to treatments with drugs widely used in cardiovascular prevention (statins, clopidogrel). Persistence was defined as the duration of time from initiation of therapy with metformin and/or sulphonylureas to discontinuation of any antidiabetic therapy. A permissible gap of 180 days based on the pharmacologic properties of the drug and the treatment situation was allowed between prefills of prescriptions. The results are reported as the rate of persistent patients at the predefined time period (12 months) in the given cohort.

Results: In patients with metformin-monotherapy ($n=115,426$) the persistence was 47.7% while the persistence was 45.4% in patients with sulphonylurea-monotherapy ($n=125,362$). In patients with metformin and sulphonylurea combination therapy ($n=15,596$) the persistence was as high as 55.8%. The treatment with modified release sulphonylureas had a higher persistence rate (47.8%) than that of traditional sulphonylureas (42.2%). The persistence of therapy using metformin 1000 mg - 60 tablets was significantly better (60.4%) at 12 months than that of other forms of metformin therapy with lower dose and smaller box analyzed together (47.7%). The persistence of therapy using metformin 1000 mg - 60 tablets was the best in patients aged between 40 and 70 years (60–66%), the persistence was reduced both in patients over 70 years of age (58%) and less than 40 years of age (20–50%). The persistence data of antidiabetic drugs proved to be higher than that of lipid lowering therapy (number of statin users 407,323, persistence: 26.3%) but lower than that of clopidogrel treatment in patients with percutaneous coronary intervention (number of clopidogrel users 20,697, persistence 73.2%).

Conclusion: Our data indicate that the persistence of initial treatment with metformin and/or sulphonylureas is far from optimal in patients with type 2 diabetes. Better diabetic care and continuous patient education (regular control, perception of treatment benefits, decrease in treatment complexity, higher use of drugs with minimal side effects, appropriate reimbursement) should be encouraged to achieve higher persistence of oral antidiabetic treatment in patients with type 2 diabetes.

938

The PANORAMA European study: biomedical and psychological characteristics of people with type 2 diabetes with and without obesity

K.G. Parhofer¹, C. Bradley², E.M. Eschwege³, L. Gonder-Frederick⁴, D. Simon⁵, H. Vandenberghe⁶, I. Wood⁷, P. Pablos-Velasco⁸;

¹Medizinische Klinik II, Klinikum der Universität München, Germany, ²Royal Holloway, University of London, UK, ³INSERM U-1018, Paris, France, ⁴University of Virginia, Charlottesville, USA, ⁵Hopital de la Pitie, INSERM U-1018, Paris, France, ⁶AstraZeneca, Zaventem, Belgium, ⁷Bristol-Myers Squibb, Uxbridge, UK, ⁸Dr. Negrin Hospital, Las Palmas University, Spain.

Background and aims: PANORAMA, a large European cross-sectional study of patients (pts) with type 2 diabetes (T2D) assessed patient reported outcomes (PROs), treatment patterns and glycaemic control. This analysis compares results between obese (body mass index, BMI ≥ 30) and non-obese (BMI < 30) pts.

Materials and methods: 5817 pts ≥ 40 y, with a diagnosis of T2D for > 1 y prior to study entry and an available medical record of > 1 y, were randomly or consecutively selected from physician practices (mainly primary care) in 9 countries. All pts received lifestyle advice. Most pts were also being treated

with either oral antidiabetes agents (OADs) or injectables (insulin or GLP-1 analogues) with or without OADs. Treatment type was unchanged in the previous 3 months. Pts completed the Audit of Diabetes-Dependent Quality of Life (ADDQoL), Diabetes Treatment Satisfaction Questionnaire (DTSQ), worry subscale of the Hypoglycemic Fear Survey-II (HFS-II) and EuroQoL-5 Dimension (EQ-5D) index and visual analogue scale.

Results: 45.6% of pts were obese. Obese pts were younger (64.2 ± 10.1 y vs 67.3 ± 10.4 y; $p < 0.001$) and characterised by shorter diabetes duration (8.5 ± 6.8 y vs 9.2 ± 7.4 y; $p < 0.001$). The obese group included more women (52.4% vs 41.2%; $p < 0.001$), fewer current smokers (12.8% vs 15.6%; $p = 0.002$) and were less educated (education after 18 y: 27.4% vs 32.3%; $p < 0.001$). Glycaemic control was worse in obese pts as shown by the proportion with $HbA_{1c} < 7\%$ (57.1% vs 67.3%; $p < 0.001$) and mean HbA_{1c} ($7.0 \pm 1.2\%$ vs $6.8 \pm 1.1\%$; $p < 0.001$). Treatment regimens were more intensive for obese vs non-obese pts: lifestyle advice alone (8.5% vs 11.1%, $p = 0.001$), 1 OAD (31.0% vs 33.2%; $p = 0.067$), 2 OADs (26.2% vs 27.6%; $p = 0.23$), 3 OADs (9.9% vs 8.1%; $p = 0.019$) and insulin \pm OAD (22.1% vs 18.5%; $p = 0.001$). Physicians rated pts' adherence to treatment and lifestyle advice as good in 66.0% vs 73.5% and 26.2% vs 49.5% of obese vs non-obese pts (both $p < 0.001$). Obese pts had higher systolic (136.1 ± 15.5 vs 133.3 ± 15.1 mmHg) and diastolic (79.5 ± 9.5 vs 77.3 ± 8.8 mmHg) blood pressure than non-obese pts (both $p < 0.001$). Obese vs non-obese pts had a greater prevalence of depressive disorders (16.0% vs 11.9%; $p < 0.001$), sleep disorders (17.5% vs 11.7%; $p < 0.001$) and microvascular complications (30.5% vs 26.7%; $p = 0.001$). Obese pts showed more negative impact of diabetes on QoL (ADDQoL), less treatment satisfaction (DTSQ), greater fear of hypoglycaemia (HFS-ws) and worse health status (EQ-5D) than non-obese pts (all $p < 0.001$).

Conclusion: Obesity in pts with T2D was associated with a greater prevalence of co-morbidities and microvascular complications, and poorer glycaemic control. Treatment regimens differed somewhat between obese and non-obese pts. Physicians rated obese pts as less likely to adhere to lifestyle advice and treatment. PRO measures showed more negative responses in obese pts. These results highlight the importance of effective weight management in the treatment of pts with T2D, and suggest that improved efforts to tailor treatments to individual lifestyles may be beneficial for obese pts.

Parental fear of hypoglycaemia in mothers of children with type 1 diabetes mellitus: a cultural comparison

L. Gonder-Frederick¹, K. Vajda¹, J. Shepard¹, F.S. Amiri², M.R. Vafa², A. Haugstvedt³, M. Graue³;

¹Psychiatry and NB Sciences, University of Virginia, Charlottesville, USA,

²Nutrition Department, Tehran University of Medical Sciences, Tehran,

Islamic Republic of Iran, ³Faculty of Health and Social Sciences, Bergen University College, Norway.

Background and aims: Fear of hypoglycemia (FoH) can affect quality of life and diabetes management and is prevalent, not only in patients with type 1 diabetes (T1D), but also in parents of children with T1D, especially mothers. While maternal FoH has been studied in several different countries and appears to have global relevance, no studies have yet investigated cultural similarities and differences. This study compared FoH in mothers of T1D children in the U.S., Norway and Iran.

Material and methods: FoH was measured with the parent version of the Hypoglycemia Fear Survey (PHFS), composed of a behavior (PHFS-B) and worry (PHFS-W) subscale, measuring, respectively, behaviors to avoid and worries about hypoglycemia or its negative consequences. The PHFS was completed by mothers of children with T1D ranging in age from 2-18 years in separate studies conducted in the U.S. ($n = 207$), Norway ($n = 103$) and Iran ($n = 60$). All parents also completed a demographic/clinical questionnaire, and their child's HbA_{1c} was measured.

Results: There were no differences in PHFS-W scores across countries, but Iranian mothers had higher mean item scores ($F = 6.5$, $p = .002$) on the PHFS-B ($\mu = 2.7$) compared to U.S. and Norwegian mothers ($\mu = 2.4$ and 2.3). The percent of mothers with PHFS item scores more than 1 SD higher than overall mean score did not differ between countries for either subscale (range for both 12.2-18%). PHFS scores did not differ for mothers of girls vs. boys for any country. Bivariate analysis found no relationship between PHFS scores and HbA_{1c} for any country, although Iranian children had significantly higher values than U.S. and Norwegian children ($F = 37.8$, $p = .000$). Mothers who reported more frequent hypoglycemia in their child scored higher on the PHFS-B for the U.S. ($p = .000$), with a trend for Iran ($p = .051$), and on the PHFS-W for Norway ($p = .025$). Exploratory factor analysis (EFA) showed the best fit for a four-factor solution for both the U.S. ($\chi^2_{(70)} = 136.2$ ($p < .00005$), RMSEA = 0.07, SRMR = 0.05, CFI = .95, TLI = .97) and Norway ($\chi^2_{(53)} = 84.3$ ($p < .00005$), RMSEA = 0.08, SRMR = 0.07, CFI = .94, TLI = .96). There was insufficient Iranian data for EFA. These four factors were generally similar for U.S. and Norwegian data, with two PHFS-B factors describing behaviors to 1) keep the child's blood glucose levels higher in some situations and 2) prevent hypoglycemia. The two PHFS-W factors described worries about the 1) child not having help or food available and 2) social and other negative consequences of hypoglycemia.

Conclusions: Mothers of children with T1DM in the U.S., Norway and Iran showed equivalent levels of worry about hypoglycemia and, in each country, mothers with female and male children worried equally. Iranian mothers, however, reported more behaviors to prevent hypoglycemia and its negative consequences. Preliminary analysis found no relationship between maternal FoH and HbA_{1c} levels, but FoH was related to children's frequency of hypoglycemia. Factor analysis results suggest that FoH is a complex construct and, as measured by the PHFS, comprised of four separate subtypes of behavioral and affective responses to hypoglycemia which are relatively consistent across the U.S. and Norway. Maternal FoH appears to have global relevance and similarities across different cultures.

Diabetes and teenagers: psychological aspects

A. Rosato¹, P. Maffioli², R. Sapone³, M. Ferraro³, C. Campolo³, G. Violi³, C. Cappelli³, G. Iacopino³, G. Derosa²;

¹Azienda ospedaliera OORR, Reggio Calabria, Italy, ²Department of Internal Medicine and Therapeutics, Fondazione IRCCS Policlinico S. Matteo, University of Pavia, Italy, ³Department of Diabetology, PST Gallico, Reggio Calabria, Italy.

Background and aims: Diabetes is one of the most common chronic diseases whose incidence is increasing steadily, it is categorized as a “social pathology”. When diabetes occurs in adolescent age, the patient must address not only the biological changes, psychological and social factors that characterize this developmental stage, but also the “challenges” that arise daily in the management of the disease. The aim of this study was to identify the specific areas of social life most affected by type 1 diabetes mellitus, in order to facilitate the implementation of psychological interventions aimed to reduce the state of discomfort experienced by patients.

Materials and methods: We enrolled 48 subjects (21 males and 27 females) with an age between 12 and 17 years, all affected by type 1 diabetes mellitus. We administered the PAID-T (Promemetic Areas in Diabetes Scale-Teen) questionnaire to evaluate the psychological implications of diabetes mellitus between teenagers. The questionnaire was composed by 26 items clustered in 4 subgroups: “Emotional tension” (TE), indicates the feelings of discomfort and emotional reactions related to the chronicity of diabetes and the perceived limits; “Self-efficacy” (AE), refers to the perception of “being able to manage the disease”; “Interpersonal discomfort” (DI), indicates the absence of social support, with particular reference to the quality of support provided by family and friends; “Discomfort for diet” (DA), concerning issues related to diet. Subjects were asked to indicate the degree of distress or discomfort created by any potential situation contained in the 26 items in the last month by circling the appropriate number on a Likert scale with 6 levels.

Results: Comparing the answers regarding the four groups of questions, we did not observe any statistically significant differences between males and females. Both males and females referred to experience a greater distress related to diet therapy, probably because the food is perceived as a “constraint” to which young people rebel against. In this subscale followed, with a slightly lower score, the existential distress related to being affected by this chronic disease which affects daily choices and actions. From the analysis of the scores obtained in the 4 subscales, emerged that adolescents show a similar level of discomfort for being people with diabetes and for the need of having to restrict the range of foods to eat, which generates the consequential discomfort for the compliance to a balanced diet. There was a significant correlation between emotional reactions (TE) and sense of self-efficacy experienced by subjects (AE), and a positive correlation between the last and the absence of socio-familial support (DI) and discomfort due to the need to undergo a nutritional therapy (DA).

Conclusion: The study is considered a useful systematic psychological consultation for patients with diabetes and, especially, for teenagers, in order to plan therapeutic interventions targeted at specific problematic areas that trouble them and produce severe consequences in the relationship with the physician team and the families.

941

A comparison of quality of life measured with the SF-36 for insulin degludec and insulin glargine in people with type 1 diabetes

P.D. Home¹, L. Meneghini², R.E. Ratner³, T. Johansen⁴, T.E. Christensen⁴, J. Jendle⁵, A.P. Roberts⁶, J.H. DeVries⁷, K.I. Birkeland^{8,9};

¹Institute of Cellular Medicine – Diabetes, Newcastle University, UK, ²Miller School of Medicine, University of Miami, USA, ³MedStar Health Research Institute, Hyattsville, USA, ⁴Novo Nordisk A/S, Søborg, Denmark, ⁵Department of Clinical Medicine, Örebro University Hospital, Sweden, ⁶Endocrine & Metabolic Unit, Royal Adelaide Hospital, Australia, ⁷University of Amsterdam, Netherlands, ⁸Faculty of Medicine, University of Oslo, Norway, ⁹Oslo University Hospital, Norway.

Background and aims: Insulin degludec (IDeg), a new-generation basal insulin, forms soluble multi-hexamers upon subcutaneous injection resulting in an ultra-long action profile. The efficacy and safety of IDeg in people with type 1 diabetes have been investigated in comparison with insulin glargine (IGlar) in a 16-week, open-label, randomised trial. Quality of life is an important aspect of efficacy in people with diabetes.

Materials and methods: Efficacy assessment utilised the validated SF-36 v.2 questionnaire, which has a two summary component scores for mental (MCS) and physical (PCS) well-being, each of four domains. IDeg (n=59) or IGlar (n=59) were injected once daily in the evening, with insulin aspart at mealtimes. At baseline, participants had a mean age of 45.8 yr, mean HbA_{1c} of 8.4 % (68 mmol/mol) and mean BMI of 26.9 kg/m², while after 16 weeks HbA_{1c} was comparable (IDeg-IGlar difference 0.10 [95% CI -0.14; 0.34] % units [1.1 [-1.5; 3.7] mmol/mol), confirmed nocturnal hypoglycaemia was less with IDeg (relative rate (RR) 0.42 [0.25; 0.69]), and overall hypoglycaemia (plasma glucose <3.1 mmol/l or requiring assistance) numerically less frequent (RR 0.72 [0.52; 1.00]).

Results: After 16 weeks, a significant improvement in SF-36 MCS of +3.01 [0.32; 5.70] was obtained for IDeg against IGlar. The difference in MCS was driven by significant differences in the social functioning (SF) domain (+8.04 [1.89; 14.18]) and the mental health (MH) domain (+2.46 [0.10; 4.82]). For MCS, Cohen's effect size was 0.42, indicating a small to medium clinically meaningful difference. SF-36 PCS was similar between insulins (+0.66 [-2.30; 3.62]). The remaining six SF-36 sub-domains showed no significant differences between IDeg and IGlar.

Conclusion: We hypothesise that the improvements in overall MCS and the underlying SF and MH domains with degludec compared to glargine relates to the observed reduction in hypoglycaemic events, but greater flexibility in the time of the basal insulin injection might also contribute. In summary, in the context of comparable overall glycaemic control to IGlar, IDeg gave improved mental well-being as measured using the MCS component of the SF-36 questionnaire.

Insulin manipulation as an indicator of psychiatric co-morbidity in children and adolescents with type 1 diabetes mellitus

G. Berger¹, I. Barrientos², G. Wagner², S. Sonnenstatter², D. Gerber², B. Rami¹, M. Fritsch¹, A. Karwautz², E. Schober¹;

¹Department of Pediatric and Adolescent Medicine, ²Department of Child and Adolescent Psychiatry, Medical University Vienna, Vienna, Austria.

Background and aims: Deterioration of metabolic control is a frequent occurrence in adolescent diabetics. Reasons cannot only be explained by physiological changes in puberty. Psychological factors contribute to this deterioration. Psychiatric co morbidity is known to be connected to worsening of metabolic control although the mechanisms are not completely clear. Non-compliance with diabetes therapy is regarded as an important factor. Insulin purging is widely known as a symptom in eating disorders in diabetes, while in contrast deliberate overdosing of insulin seems to be less frequent. In our study we aimed to assess the rate of insulin manipulation and a possible association with psychiatric co morbidity and metabolic control.

Materials and methods: 241 type 1 diabetes patients (age range 10-22 years) with a diabetes duration of >1 year from 21 diabetes outpatient clinics in Austria were included in the cross sectional study. 103 (42.7%) of the patients were males. Medical data was derived from medical records. Patients were interviewed with standardized instruments, the Diabetes Self-Management Profile (DSMP) interview and the Kinder-DIPS. T-Test, U-Test and CHI2-test were used for comparison.

Results: Based on the DSMP-Interview adherence to prescribed insulin dosage was assessed. 42.7% of the patients (n=103) were found to be compliant, 27.8% (n=67) had management problems (unintended over- or under-dosage of insulin) and 29.5% (n=71) patients reported deliberate insulin manipulation in terms of under-dosing (24.1%) and over-dosing (22.8%) their insulin. With the Kinder-DIPS psychiatric co morbidity was screened in all patients. Patients with management problems and compliant patients did not show any elevation in prevalence of psychiatric co morbidity. In the manipulating subjects we found elevated levels of depression (5.6%vs 1.0%, p<.05), specific phobia (7.0%vs 1.0%,p<.05), social phobia (5.6%vs 0%,p<.05) and eating disorders (EDNOS 7.0%vs 0%, p<.05) and highly elevated subclinical specific phobia (11.3%vs 0%, p=.001). HbA1c levels were higher among the manipulating patients (8.65%vs 7.81%, p=.001), their BMI was elevated but not significantly (BMI-SDS .176vs -.191, p=.06). Manipulating patients had more often ketoacidosis with the need of hospitalization in the past year (34.2%vs 14.7%, p<.05). Manipulating subjects were significantly older (15.00 years) than compliant subjects (14.00 years, p=.004) and more girls (69%) than boys (31%) were found in the manipulating group (p=.001).

Conclusion: Insulin manipulation can be surmised as a psychological parameter and as an indicator of psychiatric co morbidity in adolescents with diabetes. Older girls are more at risk and there is a significant impact on metabolic control. Further research is needed, especially a screening tool for insulin manipulation.

Differences in perceptions of diabetes responsibility and dietary self-efficacy in relation to adolescent and parental diabetes distress

J. Walsh¹, G.U. Law¹, V. Queral¹, S. McGovern¹, H. Napier², A. Nouwen¹;

¹School of Psychology, University of Birmingham, ²Psychology, Universities of Coventry and Warwick, Coventry, UK.

Background and aims: Having to care for diabetes is often stressful to both adolescents with type 1 diabetes (T1DM) and their parents. Negative beliefs about diabetes and its perceived consequences, lack of self-efficacy, conflicts regarding responsibility for self-care activities, and poor diabetes control may all contribute. However, few studies have examined the role of differences in perceptions between adolescents and their parents regarding diabetes responsibility and self-efficacy in relation to distress. The aim of this study was to examine whether differences in perception of dietary self-efficacy and diabetes responsibility are associated with adolescent and parental diabetes distress.

Materials and methods: 213 adolescents with T1DM (47% male) and one of their parents, completed questionnaires assessing dietary self-efficacy, illness beliefs, diabetes distress, self-care activities and family responsibility. Demographics and illness-related variables, BMI and HbA1c were also assessed.

Results: Hierarchical regression showed that when controlling for age, sex, HbA1c and duration of diabetes, diabetes distress of adolescents with T1DM was significantly predicted by their dietary self-efficacy beliefs ($\beta = -0.38$, $p < 0.0001$) and beliefs that diabetes has negative consequences ($\beta = 0.19$, $p < 0.01$). Disagreements regarding diabetes self-care and self-efficacy between parent and adolescent were not significant predictors of adolescent distress (all $p > 0.30$). The model explained 23% of the variance in adolescent diabetes distress. Parental diabetes distress was significantly predicted by parent perception of adolescent dietary self-efficacy ($\beta = -0.42$, $p < 0.0001$), and by diabetes responsibility disagreements when both claim responsibility ($\beta = 0.15$, $p < 0.04$). Neither differences in dietary self-efficacy nor diabetes responsibility when no one claimed responsibility were significant predictors of parental distress ($p > 0.40$). The model explained 25% of the variance in parental diabetes distress.

Conclusion: For adolescents with T1DM, diabetes distress was associated with a lack of confidence in their ability to follow the diet and a belief that doing so would lead to negative consequences. Disagreement between parent and adolescent with regard to self-efficacy and self-care is not related to distress in the adolescent. On the other hand, when parents doubt the ability of their adolescent to manage the diet and/or when there is disagreement regarding self-care activities, such that both claim responsibility, parents are more distressed. Parental distress is therefore likely to result from conflict surrounding these disagreements. When there is disagreement with no one claiming responsibility, parental distress is not increased possibly because it does not lead to conflict.

944

Psychological interventions in a specialised diabetes hospital: differences between patients with type 1 and type 2 diabetes

M. Janert, B. Weiss, L. Lemmer, M.A. Nauck;

Diabeteszentrum Bad Lauterberg, Germany.

Background and aims: Psychological problems are common in patients with type 1- and type 2-diabetes. Especially during in-patient diabetes treatment, a psychological intervention is often a mandatory component of therapy. The aim of this study is to evaluate possible differences in psychosomatic diagnoses applicable to patients with type 1- and type 2- diabetes and which problem areas connected with them.

Materials and methods: Over 14 months, 161 out of 848 treated patients with type 1-diabetes (19.0 %) and 252 out of 1725 patients with type 2-diabetes (14.6 %, $p = 0.0053$) received psychological evaluation and treatment. Patients with type 1- and type 2-diabetes differed regarding age (42 ± 15 vs. 58

± 12 yrs., $p < 0.0001$), BMI (26.1 ± 7.6 vs. 34.8 ± 8.3 kg/m², $p < 0.0001$), but not concerning gender distribution (m/f: 75/86 vs. 118/134, $p = 1.0$) and HbA_{1c} (9.5 ± 2.1 vs. 9.1 ± 1.8 %, $p = 0.10$). Statistical analyzes: χ^2 -test, ANOVA, results were reported as proportions (%), mean values and standard deviations.

Results: The most common diagnoses in both groups were neurotic, stress-related and somatoform disorders (ICD F 4), followed by mood (affective) disorders (ICD F3; slightly more common in type 2-diabetes; $p = 0.24$), behavioral syndromes associated with physical factors (ICD F5; more common in type 1-diabetes, $p = 0.022$) and disorders due to psychoactive substance use (ICD F1; more common in type 1-diabetes, $p = 0.016$). Regarding age distribution the patients with type 1- and type 2-diabetes differed significantly ($p < 0.0001$), but the distribution of diagnoses among particular age groups showed no significant differences. Commonly articulated problem areas were family conflicts (25.4 %), coping with the illness (24.0 %), job problems (14.3 %) and dealing with grief (8.7 %). In 25.9 % (type 1-diabetes: 30.4 %, type 2-diabetes: 23.0 %; $p = 0.11$) a further psychotherapeutic out-patient treatment and in 1.2 % an in-patient treatment was recommended.

Conclusion: Psychiatric disorders are common in patients at a specialised diabetes hospital and often need psychological, psychosomatic and psychotherapeutic treatment during the in-patient treatment and afterwards. The distribution of the psychiatric diagnoses is similar in patients with type 1- and type 2-diabetes, especially when regarding the age groups. Similarly, there is no obvious difference in problem fields between patients with type 1- and type 2-diabetes, especially when age categories are taken into account.

Non-healthy food of higher psychosocial value than healthy nutrition? Insights from a European study on overweight children and teenagers

B. Schau¹, M. Bielfeldt²;

¹Medical Affairs, Omron Healthcare Europe, Mannheim, Germany,

²Perleberg Pharma Partner, Barcelona, Spain.

Background and aims: Obesity is a growing health epidemic in developed and developing countries and consequently the risk of developing diabetes at early ages. New tendencies concentrate on the prevention of overweight and therefore focus on children and teenagers. Consequently the right strategy in the treatment and education of overweight children and teenagers and their parents becomes increasingly important. Healthy nutrition is one of the basic formats therapy is based on. The question is whether we have to redefine what is understood as healthy food, in terms of considering not only the nutritional values, but also the psychological and social value of food.

Materials and methods: We undertook a qualitative research in 5 European countries (Germany, UK, France, Italy, Spain) to obtain insight into attitude and expectations of mothers of overweight children and teenagers (N=90), children and teenagers (N=81) and the involved physicians (N=20) and health care authorities (N=15).

Results: Our study revealed changing eating habits among children and teenagers is far more complex than just becoming accustomed to eating more balanced meals. Apart from a psychological component (good taste, joy, self esteem) a strong psycho-social dimension was detected. Food is a link between mothers and children with daily meals and snacks used to maintain this social connection. By offering the children's preferred food mothers establish an ongoing interchange of reward, understanding and affection. Motivational barriers to change nutritional habits of mothers and children/teenagers are strongly influenced by this psycho-social dimension. Physicians emphasized the importance to increase the success rate of the therapy but at the same time mentioned a lack of resources to be able to consider the complex image of nutrition in all its dimensions. Present strategies are often based on reducing eating habits without offering a substitution for the missing psychosocial values to families. Thus, successful new strategies should focus on adding immediate psychosocial values to the children's and teenager's life (e.g. family events including physical activity) that compensate perceived negative changes (food reduction).

Conclusion: To successfully address the challenge of overweight among children and teenagers, and to reduce the risk of diabetes among children, teenagers and adults, we need to consider the psycho-social dimension of nutrition and find ways to substitute the role certain food plays in this sense, with positive experiences relating to an active family life.

The effect of deprivation and HbA_{1c} on hyperglycaemic admission to hospital in type 1 diabetes

L. Govan, Scottish Diabetes Research Network Epidemiology Group; Public Health and Health Policy, University of Glasgow, UK.

Background and aims: HbA_{1c} may be a useful tool in defining that part of the population likely to suffer morbidity and therefore incur an increase in hospital admissions in the short and medium term. We have previously found a positive association between increasing HbA_{1c} levels and risk of hospital admission in the Scottish type 1 diabetes population. In the general population deprivation has also been linked to increased risk of admission to hospital. This study aims to examine how deprivation affects admission to hospital for people with type 1 diabetes in Scotland.

Materials and methods: The Scottish Care Information - Diabetes Collaboration (SCI-DC) is a dynamic national register of diagnosed cases of diabetes in Scotland. These data were linked to centralised data on hospital admissions from Information Services Division (ISD) of NHS National Services. We identified 24,760 people with type 1 diabetes during January 2005 to December 2007 and include 21,436 patients with complete recording of covariates. Patients were divided into deciles according to levels of HbA_{1c}. Hyperglycaemic admission to hospital was the primary outcome (diabetes with ketoacidosis, ICD10: E10.1, E14.1). Logistic regression models were used to estimate the association between hyperglycaemic admissions and HbA_{1c} (expressed with decile 3 as referent, mean HbA_{1c} 7.86%, range 7.66%–8.05%), deprivation quintiles (referent quintile 1, least deprived), and adjusted for potential confounding factors including smoking status, age, sex, previous vascular disease, creatinine, body mass index and diabetes duration.

Results: There was a J-shaped relationship of HbA_{1c} to hyperglycaemic admissions (Figure) with highest likelihood of admission in the highest HbA_{1c} decile (adjusted odds ratio 9.68, 95% confidence interval 7.13–13.13). People in the top decile of HbA_{1c} (10.8%–18.4%) were younger (average 24 (sd 11) for females and 27 (sd 12) for males vs 38 (sd 10) and 45 (17) in decile 3). Even with adjustment for other covariates including HbA_{1c}, females had a consistently higher risk of admission compared to males (OR 1.45, 95%CI 1.28–1.65). There was a substantial effect of socioeconomic class on odds of admission. Compared to the least deprived quintile, odds of admission increased with deprivation (OR 2.84, 95%CI 2.32–3.47 for most deprived). Compared to the least deprived quintile, the most deprived quintile had, on average, an additional 194 hyperglycaemic admissions per year in the top HbA_{1c} decile (>12%). Assuming an average cost of £1702 per hyperglycaemic admission, deprivation accounts for an additional £330k per year.

Conclusion: While for all groups, high mean HbA_{1c} values predict admission to hospital for hyperglycaemia, females and people from more deprived parts of the community have a further increase in admissions. This work highlights a group who might be usefully supported to try to reduce hospital admissions.

Cerebral resting-state default mode network changes in patients with type 1 diabetes with and without microangiopathy relate to cognitive functions

R.G. Ijzerman¹, M.M. Schoonheim², E. van Duinkerken^{1,3}, E.J. Sanz-Arigita², M. Klein³, F.J. Snoek³, F. Barkhof², M. Diamant¹;

¹Diabetes Center / Department of Internal Medicine, ²Department of Radiology, ³Department of Medical Psychology, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: At rest, the brain shows consistently active regions forming circumscribed neuronal networks detectable using resting-state functional magnetic resonance imaging (RS-fMRI). One such network, the Default Mode Network (DMN), is considered to be especially important for cognitive functions. This network consists of the medial prefrontal cortex, posterior and anterior cingulate and precuneus, superior parietal cortex, and temporal regions such as the hippocampus. Activity, or synchronisation, in the DMN in for example Alzheimer's disease and multiple sclerosis, increases in the early phases of the disease and decreases with disease progression. As type 1 diabetes (T1DM), in particular in the presence of microangiopathy, is associated with cognitive decline, DMN synchronisation changes might be expected, but this has hitherto not been investigated. We assessed DMN activity in T1DM patients with and without microangiopathy and matched controls and the correlation between DMN synchronisation and cognitive functions.

Materials and methods: Forty-nine T1DM patients with, 52 T1DM patients without microangiopathy and 48 controls underwent cognitive testing for general cognitive ability, memory, information processing speed, executive functions, attention, motor- and psychomotor speed, and MRI, including a 3D T1 structural and a RS-fMRI scan. The DMN was identified using MELODIC, part of FSL 4.1 software. Group differences were assessed on a voxel level using dual regression. Analyses were corrected for age, gender, depressive symptoms and multiple comparisons. Mean DMN synchronisation in patients was used to determine its relationship with cognitive functions and disease related variables.

Results: T1DM patients with microangiopathy were significantly older, had higher HbA_{1c} levels, depression scores and performed worse on cognitive testing, as compared to the other groups (all $P < 0.05$). Across all subjects, DMN synchronisation was found in the areas described above. In patients, synchronisation of DMN was positively associated with information processing speed ($r = 0.266$; $P = 0.023$) and negatively with age and T1DM onset age ($r = -0.297$; $P = 0.002$ and $r = -0.202$; $P = 0.042$). When comparing all groups on DMN synchronisation, an increase was found in the right middle temporal gyrus in T1DM without microangiopathy relative to controls ($P < 0.05$), but not in T1DM with microangiopathy.

Conclusion: We found DMN synchronisation indeed correlated with cognitive functions and that on group level this synchronisation is slightly different in T1DM patients without microangiopathy compared to controls. These results seem in line with the compensatory mechanism to prevent cognitive decline seen in other neurological diseases. Further study needs to determine possible changes in DMN synchronisation over time and its exact impact on cognition.

The association between adherence to insulin prescriptions and HbA_{1c} among patients with type 1 diabetes

M. Linnemann Jensen, B. Carstensen, A.A. Nielsen, D.R. Witte, P. Rossing, T.P. Almdal; Steno Diabetes Center A/S, Gentofte, Denmark.

Background and aims: The degree of adherence to the prescribed insulin regimen is thought to play an important role in determining long term glycaemic regulation among patients with type 1 diabetes (T1DM). Our aim was to quantify the effect of adherence to insulin prescriptions on HbA_{1c} based on individual record linkage of electronic records.

Materials and methods: We studied 3,807 T1DM patients followed up between 1998 and 2009, some patients with electronic recordings of having been referred as early as 1996. Measurements of HbA_{1c} and registrations of prescribed daily doses at the T1DM outpatient clinic in a specialised diabetes hospital since 1998 were linked to records of filled prescriptions from the Register of Medicinal Product Statistics supplied from the Danish Medicines

Agency. The degree of insulin adherence was calculated as the proportion of days a patient had possession of sufficient insulin to cover his or her prescription. Adherence as well as the average prescribed daily dose of insulin during the 120 days prior to each HbA_{1c} measurement was considered comprising a total of 39,526 observations, with each patient contributing multiple HbA_{1c} measurements. A standard linear random coefficient model was used for analysis.

Results: At the end of 2009 the 3,807 patients (54.3 % men) had had a median attendance at the hospital of 12.3 years (minimum 0.1 and maximum 14.0 years). Mean age at beginning of follow-up in 1998 was 40.8 years (SD: 16.7 years) with a mean duration of diabetes of 16.7 years (SD: 13.3 years) at referral to the outpatient clinic. A 0.1 (10%) higher degree of adherence to the prescribed insulin dose was associated with a 0.006 percentage point (95% CI: -0.011 ; - 0.001) lower HbA_{1c}. However, the variation between patients of the estimate showed a SD of 0.254, indicating non-homogeneity. Eighty three % of the patients had a degree of adherence to insulin prescriptions of 1.0 and the 10th percentile was 0.39. There was a significant negative association between average prescribed daily doses and HbA_{1c}, in accordance with prescription of increased doses to patients with poor glycaemic control.

Conclusion: As the level of HbA_{1c} and the prescribed dose are interdependent in a continuous, iterative process consisting of an HbA_{1c} measurement and subsequent adjustment of the prescribed dose, a traditional approach to estimation of associations between medication adherence and glycaemic control is problematic. Methods based on changes in prescribed dose and adherence will need to be developed.

PS 082 Psychological aspects: type 2 diabetes

Change in health status (EQ-5D) over 5 years among individuals with and without diabetes

S. Grandy¹, K.M. Fox², SHIELD Study Group;

¹AstraZeneca LP, Wilmington, ²Strategic Healthcare Solutions, LLC, Monkton, USA.

Background and aims: This study assessed the change in health status and health-related quality of life over 5 years among individuals with and without diabetes.

Materials and methods: Respondents to the US Study to Help Improve Early evaluation and management of risk factors Leading to Diabetes (SHIELD) surveys completed the EuroQol-5D (EQ-5D) quality-of-life questionnaire at baseline (2004) and 5 years later (2009). The two EQ-5D components (visual analog scale [VAS] score and the health index score) were computed at baseline and year 5, and the change over 5 years was measured for individuals with type 2 diabetes (T2DM) and those without diabetes. Linear regression models were used to determine change in EQ-5D score controlling for age, gender, race, education, household income, body mass index (BMI), and diabetes status (T2DM, no diabetes).

Results: For respondents with T2DM (n = 1,741), 60% were women and mean age was 61 years compared with 62% women and mean age of 56 years for respondents without diabetes (n = 4,543). There was a significantly greater decline in the EQ-5D index score in the T2DM group (-0.031 [SD 0.158]), compared with those without diabetes (-0.016 [0.141]) over the 5-year period (p = 0.001). Compared with respondents without diabetes, those with T2DM had a larger reduction in EQ-5D index score, after controlling for age, gender, race, education, income, and BMI (p = 0.001). The EQ-5D VAS score declined over 5 years for both groups: -1.42 (18.1) for T2DM group, and -0.63 (15.8) for group without diabetes, but the difference was not significant either before (p = 0.09) or after (p = 0.12) controlling for demographics (p = 0.12). Among the T2DM respondents, the decline in EQ-5D index score was significantly greater among those who had reported diabetes complications over the 5 years, compared with those without complications: -0.058 for retinopathy vs. -0.028 for no retinopathy (p = 0.02), and -0.061 for neuropathy vs. -0.020 for no neuropathy (p < 0.001).

Conclusion: Over a 5-year period, health status of respondents with T2DM declined significantly, compared with those with no diabetes, indicating that the burden of the disease has a long-term detrimental impact on the quality of life of patients living with type 2 diabetes.

Validation of the (short) Exercise Self-efficacy Scale (ESS) in Dutch primary care patients with type 2 diabetes mellitus

M. van der Heijden, F. Pouwer, V.J.M. Pop;

Department of Medical Psychology and Neuropsychology, Tilburg University, Netherlands.

Background and aims: Exercise is an essential element of type 2 diabetes (T2DM) management, as it can lower the risk of complications. However, an estimated 60-70% of T2DM do not exercise enough. One of the psychosocial constructs that is believed to influence physical activity behaviour, is exercise self-efficacy. Exercise self-efficacy is the extent to which people believe they can maintain or improve their level of physical activity. The purpose of this study is to validate the Dutch (short) version of the Exercise Self-efficacy Scale (ESS) in a T2DM Primary Care sample.

Materials and methods: T2DM patients (n=322) with a BMI >25 and <80 years old filled out the ESS and the Short Questionnaire to ASsess Health enhancing physical activity (SQUASH). The ESS contains 18 items describing situations that might interfere with adherence to exercise routine. The ESS rates the degree of confidence on a 100-point scale, higher scores indicating more self-efficacy. The total score of the ESS is calculated as the mean of the items. ESS construct-validity was assessed (principal axis factor analysis, Cronbach's α , inter-item- and item-total correlations). Moreover, the concurrent validity with the SQUASH outcomes 'total-' and 'leisure time minutes/week of moderate to vigorous intensity physical activity' was evaluated. As

these outcomes are not normally distributed, non-parametric tests were used (Spearman correlation and Mann-Whitney U). Finally, similar analyses were performed using a short (5-items) version of the ESS.

Results: Median total score on the ESS was 41.8 with a range between 0 and 99. A low score on the ESS was defined as a score ≤ 40 . All ESS item scores ranged from 0 to 100, without any floor- or ceiling effect. The principal axis factor analysis suggested one underlying factor, explaining 54% of the total variance. Factor loadings varied between 0.48 and 0.83. Inter-item correlations varied between 0.24 and 0.79, item-total correlations varied between 0.47 and 0.81. Cronbach's α coefficient was 0.95. The median (range) of the SQUASH outcomes 'total-' and 'leisure time physical activity' were 420 (0–4620) and 270 (0–2640) respectively. The correlations of the ESS with 'total-' and 'leisure time physical activity' were 0.18 ($p = 0.002$; effect size: 0.37) and 0.23 ($p < 0.001$; effect size: 0.47) respectively. Patients with a low ESS score (≤ 40) had lower 'total-' ($p = 0.017$) and 'leisure time physical activity' ($p = 0.003$) compared to subjects with a high ESS score (> 40). Subsequently, a short version of the ESS was developed including 5 items. Construct analysis revealed a one factor solution, explaining 69% of the variance. Factor loadings varied between 0.78 and 0.86. The item-total correlation varied between 0.75 to 0.81 with a Cronbach's α coefficient of 0.92. The short-ESS correlated strongly with the total-ESS (0.94). The correlations of the short-ESS with the SQUASH outcomes 'total-' and 'leisure time physical activity' were 0.15 ($p = 0.01$; effect size: 0.30) and 0.20 ($p < 0.001$; effect size: 0.41) respectively. Patients with a low short-ESS score (≤ 40) had lower 'total-' ($p = 0.017$) and 'leisure time physical activity' ($p < 0.001$) compared to subjects with a high score (> 40).

Conclusion: This study is the first to show the validity of the ESS in a large sample of T2DM patients. The ESS and its short version might be useful in (intervention) research on physical activity in T2DM patients.

Clinical Trial Registration Number: 2734

Application of the STCD₂ treatment satisfaction questionnaire in a cohort of caregivers of dependent type 2 diabetic, hospitalised patients

J.I. Herrero-Herrero, J. García-Aparicio;

Los Montalvos Internal Medicine Service, University Hospital, Salamanca, Spain.

Background and aims: The STCD₂ questionnaire has been recently validated to ascertain the satisfaction with the treatment of the caregivers of dependent type 2 diabetic patients. Our survey was designed to analyze the data after applying this methodology in a cohort of subjects studied in a hospital setting.

Materials and methods: The eight-item STCD₂ questionnaire was applied to the caregivers of consecutive, dependent, type 2 diabetic patients receiving anti-diabetic medication, admitted (for any reason) to the internal medicine service of our hospital. The questionnaire, referred to the satisfaction with the treatment received before admission, was administered in an interview by a member of the research team during the hospitalization period. Epidemiological and clinical data of the patients, as well as epidemiological information of their caregivers was also collected and analyzed.

Results: The STCD₂ questionnaire was administered to 132 subjects. The patients they were caring for (women: $n = 87$, 65.9%; mean age \pm SD: 84.2 ± 6.8 years) came from nursing homes in $n = 48$, 36.4% cases, and had scores in the Lawton and Brody scale of mean \pm SD: 1.0 ± 1.4 points (median: 0.0 points) and in the Barthel scale of mean \pm SD: 38.5 ± 27.7 points (median: 42.5 points). At admission, they received insulin or insulin analogues in $n = 53$, 42% cases; oral anti-diabetic agents in $n = 63$, 47.7% cases; and both in $n = 16$, 12.1% cases. The number of daily administrations of anti-diabetic medication was one in $n = 59$, 44.7% cases, and ≥ 3 in $n = 36$, 27.3% cases. Mean \pm SD values of HbA_{1c} at admission were 7.3 ± 1.5 %. Surveyed caregivers (women: $n = 104$, 78.8%; mean age \pm SD: 50.5 ± 15.6 years) had a secondary or high educational level in $n = 72$, 54.6% cases, they were remunerated employees in $n = 48$, 36.4% cases, and they utilized a mean \pm SD of 12.6 ± 7.3 hours per day in the care of the dependent diabetics. They revealed to be 'very' or 'fairly' satisfied with the treatment that received the patients they cared for in $n = 92$, 69.7% cases. Regarding specific areas, the same high levels ('Very satisfied' / 'Fairly satisfied') of satisfaction were reached in: satisfaction with the 'blood sugar levels', $n = 83$, 62.9%; satisfaction with the acceptance of the treatment by the patient, $n = 94$, 71.3%; satisfaction with the easiness of administration of medication, $n = 94$, 71.3%; satisfaction with the number of administrations per day of the medication, $n = 95$, 71.9%; and satisfaction with their own knowledge about the treatment of diabetes, $n = 52$, 39.3%. Statistically significant correlations were detected between the score of global treatment satisfaction and number of administrations per day of the medica-

tion ($r = -0.27$, $P = 0.002$), and level of HbA_{1c} ($r = -0.32$, $P = 0.000$). Groups of caregivers of patients receiving short acting insulin or analogues, and insulin plus oral anti-diabetic agents showed significantly lower levels of satisfaction (χ^2 , $P = 0.000$ and $P = 0.001$, respectively). In a logistic regression analysis, HbA_{1c} numbers were identified as predictors of caregiver satisfaction (OR: 0.560, IC 95%: 0.416–0.753, $P = 0.000$).

Conclusion: Our data suggest that simplicity in anti-diabetic therapy has to be considered when addressing the management of dependent type 2 diabetic patients if satisfaction of their caregivers is an additional objective.

952

Development and validation of a treatment satisfaction questionnaire for caregivers of dependent type 2 diabetic patients (STCD₂)

J. García-Aparicio, J.I. Herrero-Herrero;

Service of Internal Medicine-Los Montalvos, University Hospital of Salamanca, Spain.

Background and aims: This study was designed to develop a diabetes-specific questionnaire for caregivers to assess their satisfaction with the treatment that receive the dependent type 2 diabetic patients under their care and to conduct its psychometric validation.

Materials and methods: After a review of the literature and field tests, a questionnaire of 'Satisfacción con el Tratamiento de los Cuidadores de pacientes Diabéticos Dependientes' (STCD₂) was elaborated. The STCD₂ questionnaire was applied to the caregivers of consecutive, dependent, type 2 diabetic patients receiving anti-diabetic medication, admitted (for any reason) to the internal medicine service of our hospital. The questionnaire, referred to the satisfaction with the treatment received before admission, was administered in an interview by a member of the research team during the hospitalization period. The questionnaire was administered again, four weeks later, in a telephonic interview to estimate the instrument test-retest reliability.

Results: The STCD₂ questionnaire contains eight items directed to assess total diabetes treatment satisfaction and treatment satisfaction in specific areas (satisfaction with the 'blood sugar levels', satisfaction with the acceptance of the treatment by the patient, satisfaction with the easiness of administration of medication, satisfaction with the number of administrations per day of the medication, and satisfaction with the caregiver own knowledge about the treatment of diabetes). Each of the 8 items are scored on a descending scale of five levels: Very satisfied / Fairly satisfied / Normal / Fairly dissatisfied / Very dissatisfied. This questionnaire was administered to a cohort of 79 caregivers. The internal consistency reliability, as estimated by Cronbach's alpha coefficient, was 0.85, indicating that the components of the scale measured the same construct. The items all significantly correlated with each other ($r = 0.21$ to 0.80 , $P < 0.001$). Stronger correlations of global satisfaction were demonstrated with satisfaction with the 'blood sugar levels' ($r = 0.74$, $P < 0.001$), with satisfaction in continuing with the current treatment ($r = 0.62$, $P < 0.001$), and with the willingness to recommend the current treatment to other people ($r = 0.62$, $P < 0.001$). Global satisfaction with treatment ($r = -0.43$, $P < 0.001$) and satisfaction with the glycaemic levels ($r = -0.57$, $P < 0.001$) showed the higher correlations with HbA_{1c}. Factor analysis identified two components explaining 72.1% of the variance. The intraclass correlation coefficient between scores on both administrations of the questionnaire was 0.89.

Conclusion: The STCD₂ questionnaire is a very easy to administer, reliable, consistent and valid instrument for measuring satisfaction with the treatment in caregivers of dependent type 2 diabetic patients.

953

Executive functioning in type 2 diabetes: results from the LifeLines cohort Study

B.H.R. Wolfenbutter¹, M.F. Elderson², J.P. Slaets³, M.M. Van der Klauw¹;

¹Endocrinology, ²Endocrinology & LifeLines Cohort Study, ³Geriatric Medicine, Univ Med Center Groningen, Netherlands.

Background and aims: People with diabetes are at increased risk of cognitive dysfunction. We investigated executive function in people with self-reported and newly-diagnosed type 2 diabetes, and compared results with non-diabetic individuals, as well as the relation with metabolic control and anthropometric measures.

Materials and methods: We studied 10,024 participants aged 30 years and above of the population-based LifeLines Cohort Study. Neuropsychological test scores were examined in one cognitive domain, i.e. executive function

with the Ruff's Figural Fluency Test (sum of unique patterns) and expressed as standardized Z-values. Diabetes was defined as self-reported ($n=226$), and newly-diagnosed by fasting blood glucose ≥ 7.0 mmol/l at screening ($n=120$). Data were analyzed using Z-scores adjusted for age with Pearson's correlation and multiple linear regression.

Results: Mean age was 49 (SD 11, range 31–88) yrs; 58% was female. RFFT score was 81 ± 22 in the non-diabetic individuals, 72 ± 23 in the newly-diagnosed group, and 68 ± 21 in the known diabetes group ($p < 0.001$). Mean age differed between groups, and was lower in the controls: 49 ± 11 , 56 ± 11 , and 59 ± 11 yrs, respectively. Compared to the controls, Z-score of RFFT was -0.22 (0.97) in the known diabetics ($p=0.001$) and -0.14 (1.06) in the newly-diagnosed ($p=0.12$). Log-transformed fasting blood glucose ($r=-0.15$), HbA1c ($r=-0.17$), age ($r=-0.37$), BMI ($r=-0.11$) and WHR ($r=-0.13$) correlated significantly (all $p < 0.001$) with RFFT-score. In multiple regression analysis, age, HbA1c, BMI and WHR proved to be independent predictors of RFFT-score.

Conclusion: Diabetes and level of glycaemic control, as well as anthropometric measures, are associated with slightly worse cognitive performance in executive function after adjustment for age.

The impact of glucose lowering agents on treatment satisfaction and psychological well-being in patients with type 2 diabetes

L. Venskutonyte¹, K. Brismar², J. Öhrvik¹, T. Rydén¹, L. Rydén¹, B. Kjellström¹; ¹Department of Medicine, ²Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Diabetes Mellitus (DM) requires a high level of self-care and commitment from the patient. Perception of different glucose lowering alternatives and their effects on general well-being is not well explored in patients with DM. The objective of this study was to determine if initiation of insulin influenced treatment satisfaction and mental well-being in such patients.

Materials and methods: In the DIGAMI 2 study patients with diabetes and myocardial infarction were randomised to insulin based treatment or treatment based on oral drugs. Information at admission and after 12 months of follow-up was available in 324 patients (median age 67 years, interquartile range 59–73; 71% men). They were evaluated by means of the Diabetes Treatment Satisfaction Questionnaire (DTSQ) and the Psychological General Well-being index (PGWB) at baseline and after 12 months. Patients with insulin-based glucose control ($n=197$) were compared to those on oral glucose lowering agents ($n=127$).

Results: There was no difference in age and gender between groups. At baseline insulin treated patients had a worse risk profile, more co-morbidities and were less satisfied with treatment (DTSQ 28.6 ± 6.5) compared to patients on oral treatment (DTSQ 30.6 ± 5.1 ; $p=0.019$). Treatment satisfaction improved significantly after 12 months in both groups and there was no longer a difference in DTSQ score between patients on insulin (30.9 ± 5.7) and oral treatment (31.8 ± 5.3 , NS). This pattern was the same in patients not previously treated with insulin but randomised to such treatment (DTSQ 31.8 ± 5.0 vs. 31.8 ± 5.3 , NS). PGWB scores were similar in the insulin and oral treatment groups at baseline (77.2 ± 6.7 vs. 78.1 ± 6.1) and after 12 months (80.2 ± 5.2 vs. 80.5 ± 5.6). The improvement in PGWB was significant in both groups. Men had higher DTSQ and PGWB scores compared with women at baseline and after 12 months. Both genders improved DTSQ and PGWB significantly over time, independent of glucose lowering treatment.

Conclusion: Insulin based glucose lowering treatment did not affect treatment satisfaction or psychological well-being negatively in patients with type 2 diabetes and myocardial infarction compared with their orally treated counterparts.

Is hypoglycaemia worrisome even for diet-only treated people with type 2 diabetes?

K. Kanc¹, J. Ostrovnik¹, M. Kos²;

¹Jazindabetes (Diabetes&Me), ²Hiša eksperimentov, Ljubljana, Slovenia.

Background and aims: Hypoglycaemia is a frequent experience in people with insulin-treated diabetes mellitus. It is presumed to be much less frequent

in OAD-treated patients and virtually non-existent in diet-only treated patients, in daily practice however, the latter two patient groups still express their worry about hypoglycaemia, which may often interfere with decision-making about the therapy up-grade and the overall success of diabetes treatment. The aim of our study was to explore to what extent do OAD and diet-only treated patients worry about hypoglycaemia.

Materials and methods: In this retrospective study, we looked at patient charts of all 611 OAD and diet-only treated patients (diabetes educated at some point), who visited our centre at least once in year 2010. Those who completed all items of the 20-item Problem Areas In Diabetes (PAID) questionnaire, as part of a routine first visit in the year, qualified for our survey: 294 completers on OAD and 141 completers on diet-only treatment (further 100 refused to complete; 76 partly completed). We looked at the question No.9: 'Worrying about low blood sugar reactions?' If they at least marked 'Minor problem' (or more), they classified as worrying about hypoglycaemia (PAID yes), if hypoglycaemia was mentioned in the chart at any time before this visit, they classified as experiencing at least one episode (Hypo yes). Sulphonylurea (SU) use(%) was added to the OAD scoring results, as it carries most risk for hypoglycaemia. Descriptive statistics was used to present the data.

Results: Patient characteristics were: 141 on diet-only (83 males; 59%), avg. (SD; range) age 61y.(10;30–82), diabetes duration 4.2y. (5.5;0–27), HbA1c 6.8% (1.2;4.7–13.8) and 294 on OAD (168 males;57%), age 62y.(11;32–89), diabetes duration 7.8(7.3;0–40), HbA1c 7.3% (1.23;5.2–12.9). Number of subjects scoring PAID and experience of hypoglycaemia, along with SU use is presented in the Table.

Conclusion: In diet-only treated patients roughly half worry about hypoglycaemia. In OAD-treated patients almost 60% worry about hypoglycaemia, among those, only one quarter actually experienced an episode; in those that did not have an episode, roughly half are those that worry. Within the OAD-treated group SU seems to play little role in understanding why people worry about hypoglycaemia or not. Worry about hypoglycaemia goes beyond the experience of hypoglycaemia, treatment mode or knowledge about diabetes, therefore other factors remain to be elucidated.

		PAID diet - only				PAID OAD	
		yes	no			yes	no
hypo	yes	2 (1,4 %)	1 (0,7 %)	hypo	yes	40 (13,6 %)	11 (3,7 %)

Psychoemotional implications of anxiety and depression on the eating behaviour of newly diagnosed type 2 diabetes patients

A. Frunza¹, C. Zetu¹, C. Ionescu-Tirgoviste¹, R.-M. Floarea²;

¹Diabetes, National Institute of Diabetes, Nutrition and Metabolic Diseases "Prof.Dr.N.C. Paulescu", Bucharest, ²Internal Medicine, "Sf. Ioan" Emergency Hospital, Bucharest, Romania.

Background and aims: Numerous studies have reported high prevalence of eating disorders among patients with type 1 diabetes mellitus, but with little evidence of the association of these disorders in patients with type 2 diabetes that associate anxiety and depression. Our aim was to establish the prevalence of anxiety, depression and eating disorders such as bulimia nervosa and binge eating disorder among patients with newly diagnosed type 2 diabetes mellitus and the implications of psychoemotional status on eating behavior.

Materials and methods: We developed a cross-sectional study, descriptive, over 80 patients with newly diagnosed type 2 diabetes mellitus who were administered standardized instruments for assessing eating disorders (Eating Attitudes Test-26), depression and anxiety (Hamilton Anxiety Scale and Hamilton Depression Scale). We have also compiled a questionnaire which includes demographic data, information on socio-professional status and socio-economic status, coronary risk factors, medical history, family history, any medication, eating habits and we've adapted various items of standardized tests for assessment of eating disorders (Eating Disorder Diagnostic Scale, Eating Disorder Examination, Eating Behavior Severity Scale). Associated we used diagnostic criteria for eating disorders from the Diagnostic Statistical Manual IV. After assessing the prevalence of bulimia nervosa and binge eating disorder in the newly diagnosed type 2 diabetic patients, we divided the

study population into two sub-groups: newly discovered type 2 diabetic patients with and without an eating disorder.

Results: 23.7% of patients with newly diagnosed type 2 diabetes associated bulimia nervosa or binge eating disorder. 38.75% of patients showed varying degrees of anxiety (48.3% mild anxiety, 42% intermediate and 9.7% severe anxiety), without statistically significant differences between patients with and without eating disorder; prevalence of depression was 21.2%, significantly higher among people with diabetes who associated an eating disorder ($p < 0.01$). High depression scores were associated with a higher daily frequency of meals and snacks and increased consumption of farinaceous products, sweets and pastries ($p < 0.01$), while patients who have elevated anxiety scores tended to limit the number of daily snacks and avoid these foods ($p < 0.01$). Glycated hemoglobin values were inversely correlated with the degree of anxiety and directly proportional correlated with depressive symptoms ($p < 0.01$). Disappointment, sadness, concern, irritability are strongly and statistically significantly related with high scores in Eating Attitudes Test-26, body mass index and glycated hemoglobin values ($p < 0.01$).

Conclusion: Binge eating disorder was the most frequent type of eating disorder associated with type 2 diabetes mellitus at onset. Psychoemotional context, anxiety and depression are related with eating behavior of newly diagnosed type 2 diabetic patients. Unlike anxious patients, depressed subjects tend to have more daily snacks and meals and a higher consumption of hypercaloric foods. Depression and eating disorders prone to a poorer glycemic profile, while glycated hemoglobin values of anxious patients proved a better metabolic profile.

957

Illness intrusiveness and the longitudinal prediction of depression in adults with newly diagnosed type 2 diabetes mellitus

A. Nouwen¹, T. Ford², A. Balan¹, D.G. White²;

¹School of Psychology, University of Birmingham, UK, ²Division of Psychology, Staffordshire University, Stoke-on-Trent, UK.

Background and aims: Although the risk of depression is low in people newly diagnosed with type 2 diabetes mellitus (T2DM), this risk increases over the first year after diagnosis. It is likely that the burden of living with diabetes and having to care for it contribute to the development of depressive symptoms. Illness intrusiveness (the perception that the illness and its ramifications disrupt valued daily activities) is associated with increased depressive symptoms in people with longstanding T2DM. Whether illness intrusiveness is a mere correlate of depression or whether it contributes to its development remains to be determined. Thus, research is needed to examine the longitudinal relationship between perceptions of the impact of diabetes and depressive symptoms during the critical period after diagnosis. It is also possible that depression occurs when people feel that they are unable to attain important life goals. To date, this has not been examined in relation to T2DM. Therefore, we examined the longitudinal relationship between perceptions of illness intrusiveness, goal self-efficacy and depressive symptoms in a sample of newly diagnosed people with T2DM.

Materials and methods: 237 people (65% male) newly diagnosed with T2DM completed questionnaires assessing depressive symptoms (BDI-short), perceptions of illness intrusiveness, and number of diabetes-related complications, on five occasions, each three months apart. On each occasion, we also assessed perceived ability to attain key life goals (goal self-efficacy) using semi-structured interviews, along with BMI and HbA1c.

Results: Over the 18-month study period, the number of people with significant depressive symptoms (BDI-short > 9) ranged from 38 (16%) at Time 1 to 22 (11%) at Time 5. Multivariable Generalised Estimating Equations (GEE) analyses, showed that both goal self-efficacy ($\beta = -0.09$, $p < 0.02$) and illness intrusiveness ($\beta = 0.20$, $p < 0.001$) were significant longitudinal predictors of depressive symptoms, even when controlling for age, sex and BMI. HbA1c and self-reported complications were not significantly associated with depressive symptoms. When changes between two adjacent time points were modeled, multivariable GEE analyses showed that changes in depressive symptoms were predicted by changes in perceived illness intrusiveness ($\beta = 0.16$, $p < 0.001$) but not by changes in goal self-efficacy or HbA1c.

Conclusion: Depressive symptoms were associated with illness intrusiveness and goal self-efficacy. However, diabetes control and self-reported complications did not contribute to the prediction of depressive symptoms over time. These results reflect a combination of cross-sectional and longitudinal associations. Changes in depressive symptoms were predicted by changes in illness intrusiveness only and not by changes in goal self-efficacy, diabetes control or complications. Overall, the results show that people who doubt

their ability to attain important life goals are more depressed. When people perceive changes in diabetes-induced disruptions of activities between time points, their depressive symptoms changed accordingly. To reduce depression in people with newly diagnosed T2DM, interventions should target perceived conflicts between valued activities and diabetes self-care activities.

Should we expect gender differences in reporting of depressive symptoms and seeking of professional help among diabetic patients?

M. Pibernik-Okanovic¹, D. Ajdukovic¹, M. Sekerija², I. Poljak³, N. Hermanns⁴;

¹Merkur University Hospital, University Clinic Vuk Vrhovac, Zagreb, Croatia,

²Croatian National Institute of Public Health, Zagreb, Croatia,

³Faculty of Humanities and Social Sciences, Zagreb, Croatia, ⁴Research

Institute of the Diabetes Academy Mergentheim (FIDAM), Bad Mergentheim, Germany.

Background and aims: Research data have shown that depressive symptoms are prevalent in persons with diabetes. Women with diabetes exhibit higher rates of depressed mood than diabetic men. Data from the general population indicate that women are more likely to seek professional help for mental health. However, research on the differences in seeking help for depression between diabetic men and women is scarce. This study was aimed at examining gender differences in responding to depression screening, reporting depressive symptoms and expressing a need for professional help in a large sample of Croatian patients with diabetes.

Materials and methods: One thousand and six hundred type 2 diabetic patients were selected from the database of patients treated at a tertiary diabetes clinic in an urban setting. They were screened for depressive symptoms by using the two-item Patient Health Questionnaire-Depression (PHQ-2) accompanied by an additional question inquiring into their need to receive professional help. The questionnaire and an envelope for a pre-paid reply was sent to the recipients by surface mail. Demographic and disease-related data were collected from patients' medical records. Response rate, prevalence of depressive symptoms and the need for professional help were compared in female versus male respondents by using chi-square test. Disease-related characteristics were compared between depressed and non-depressed groups by t-test.

Results: The response rate of 42% was obtained, yielding a sample size of $n = 674$ (49% female, aged 62 ± 2 years, with HbA1c of 7.1 ± 1.3 , and BMI of $29.9 \text{ kg/m}^2 \pm 4.7$). Forty-seven percent of the responders reported having experienced at least one of the depressive symptoms, while 35% reported both symptoms. Of the responders, 45% reported low mood and 37% a lack of interest and pleasure. A need for receiving professional help was expressed by 78% patients burdened by depressive symptoms. No gender differences were observed in either the response rate (chi-square=0.02, $p = 0.90$), the presence of depressive symptoms (chi-square=0.35, $p = 0.84$) or the expressed need to receive professional help (chi-square=0.04, $p = 0.85$). Patients with depressive symptoms had a higher BMI than those who were symptom-free (30.2 ± 4.9 vs 29.3 ± 4.5 , $p = 0.03$). HbA1c values were shown to be nearly significantly higher in patients with elevated depressive symptoms ($7.2\% \pm 1.3$ vs $7\% \pm 1.3$, $p = 0.07$) whereas other metabolic parameters, including total cholesterol, triglycerides, LDL, HDL and albumin/creatinine ratio did not differ between the groups (all p 's $> .05$).

Conclusion: Unexpectedly, no differences were found between women and men with diabetes in responding to depression screening, reporting depressive symptoms and expressing a need for professional help. Further research is needed to clarify whether these data are due to self-selection inherent to the screening process or they reflect specific features in persons with diabetes.

Self-monitoring of glucose in blood or urine does not increase diabetes-specific distress in non-insulin treated patients with type 2 diabetes: results from the IN CONTROL-trial

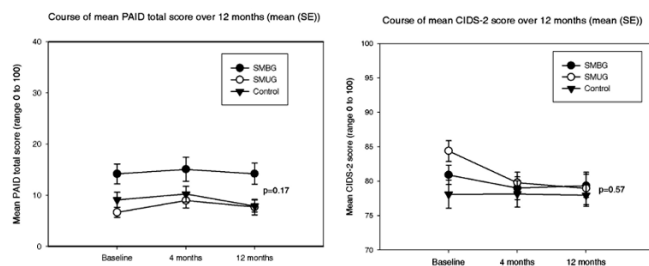

U.L. Malanda¹, S.D.M. Bot², P.J. Kostense³, F.J. Snoek⁴, J.M. Dekker³, G. Nijpels¹;¹Department of General Practice, ²Departments of General Practice & Epidemiology and Biostatistics, ³Department of Epidemiology and Biostatistics, ⁴Department of Medical Psychology, EMGO Institute for Health and Care Research, Amsterdam, Netherlands.

Background and aims: Self-monitoring of glucose is widely considered as an important tool in diabetes self-management. Concerns about a possible negative impact of self-monitoring on quality of life and self-care behaviours have risen. We investigated the effects of self-monitoring of glucose in blood or urine, on diabetes specific distress and self-efficacy, compared to usual care in non-insulin treated patients with type 2 diabetes.

Materials and methods: We recruited 181 patients from 3 diabetes care systems with type 2 diabetes treated with diet or oral hypoglycaemic agents, (mean (SD) HbA1c of 58 (15) mmol/mol, mean age 61.5 (7.8) years, median (q1, q3) diabetes duration of 5 (3, 9) years) and randomised them to either SMBG (pre- and post-prandial testing around main meals, two separate days a week) (n=60), SMUG (post-prandial testing after dinner, two separate days a week) (n=59) or Usual Care (n=62). All patients received standardized diabetes care with education. The intervention groups were provided with a flowchart and instructions how to interpret self-monitoring results and what actions to take. Self-administered questionnaires were completed before randomisation at baseline, 4 and 12 months follow-up. Intention-to-treat (ITT) analyses were performed. Primary outcome measures were between group differences in diabetes specific distress (PAID; range 0 to 100) and self-efficacy (CIDS-2; range 0 to 100) after 12 months. Cut off points were 40 for PAID, indicating high distress and 71.5 for CIDS-2 indicating high self-efficacy.

Results: There were no statistically significant between-group differences in changes in PAID ($p=0.17$) and CIDS-2 ($p=0.54$) after 12 months. Mean difference in PAID over 12 months between SMBG and Usual Care, adjusted for baseline levels was 2.56 points (95% CI -0.12 to 5.24) and between SMUG and Usual care 0.81 points (95% CI -2.10 to 3.72). Mean difference in CIDS-2 over 12 months between SMBG and usual care, adjusted for baseline levels was 0.49 points (95% CI -2.65 to 3.64) and between SMUG and Usual Care -1.43 points (95% CI -4.95 to 2.09).

Conclusion: The study demonstrated that self-monitoring of glucose in blood or urine did not promote diabetes related distress and suggest that self-monitoring had no clinical relevant impact on diabetes specific quality of life in moderately controlled patients with type 2 diabetes treated with diet or oral hypoglycaemic agents. Figure 1: Course of mean PAID and CIDS-2 scores over 12 months (High scores indicate high distress / self-efficacy)

Self-monitoring of glucose levels in blood or urine does not change illness beliefs about control: results from the IN CONTROL-trial

J.D. van der Berg¹, U.L. Malanda¹, S.D.M. Bot², P.J. Kostense³, F.J. Snoek⁴, J.M. Dekker³, G. Nijpels¹;¹Department of General Practice, ²Departments of General Practice & Epidemiology and Biostatistics, ³Department of Epidemiology and Biostatistics, ⁴Department of Medical Psychology, EMGO Institute for Health and Care Research, Amsterdam, Netherlands.

Background and aims: The effectiveness of self-monitoring of glucose in non-insulin requiring type 2 diabetic patients has been under discussion for years. The IN CONTROL-trial explored whether self-monitoring can affect diabetes specific emotional distress and self-efficacy in these patients. The hypothesis was based on the common sense model and supposed that feedback from self-monitoring allows adaptation of illness perceptions, which supported by adaptations of perceived social support, mediate changes in distress and self-efficacy. To explore the theory underlying the effects of self-monitoring, this study analyzed whether self-monitoring of glucose changed illness perceptions at short-term.

Materials and methods: The 181 participants of the IN CONTROL-trial, recruited from three diabetes care systems, were randomized to the intervention groups self-monitoring of blood glucose (SMBG, n=60) and self-monitoring of urine glucose (SMUG n=59), and Usual Care group (UC, n=62). Participants in the intervention groups received a training and a flowchart with instructions, and all participants received standard diabetes care with education. They completed at baseline, two and four months after baseline self-reporting questionnaires assessing illness beliefs with the revised Illness Perception Questionnaire (IPQ-R) and the Multidimensional Diabetes Questionnaire (MDQ). The domains "personal control" (score range 6 to 30) and "treatment control" (score range 5 to 25) of the IPQ-R, and "perceived social support" and "perceived severity" of the MDQ (score range 0 to 6) were used. Higher scores indicate higher self-reported experience of "control", "social support" or "severity". Change scores after two and after four months of the four subscales were calculated and compared between SMBG and Usual Care groups, SMUG and Usual Care groups and SMBG and SMUG groups. A complete case analysis was performed as subgroup analysis.

Results: All illness perception questionnaire and multidimensional diabetes questionnaire change scores after two months were small (range from -0.36 to 1.16) and not statistically significant. After four months all change scores were small as well (range from -0.47 to 0.98) and not statistically significant different between the three groups.

Conclusion: This study demonstrated that self-monitoring of glucose levels in blood or urine did not change illness perceptions after two and after four months.

Postprandial urine tests for glucose: a reliable, painless and inexpensive monitoring of metabolic control in type 2 diabetes without insulin treatment

N. Müller, D. Schuldt, K. Kämmer, G. Wolf, U.A. Müller;

Dept. Internal Medicine III, University Hospital Jena, Germany.

Background and aims: Over 100 years ago A. Bouchardat, and, subsequently, E. P. Joslin trained people with diabetes to test their urine for glucose. Postprandial urine tests for glucose are promoted as a method for self monitoring in type 2 diabetes without insulin treatment. Nevertheless, the relation be-

tween the results of postprandial measurements of glucosuria by the patients and HbA1c levels has yet to be studied systematically. Blood glucose monitoring is over 10-times more costly and heavily promoted. Therefore, the aim of this study was to evaluate the association between postprandial glucosuria and HbA1c. Our hypothesis being that urine testing for glucose is a reliable method for identifying a good level of metabolic control.

Materials and methods: Data from 216 patients (47.7 % female) with diabetes mellitus type 2 without insulin treatment were analysed (avg. age 62.3 years, time since diagnosis of diabetes 7.0 years, BMI 30.7 kg/m², HbA1c 6.6 %, 25% were treated with diet without oral antidiabetic agents). The patients had been recruited within the frame of two cross-sectional studies in a university clinic for endocrinology and metabolic diseases and three practices for general medicine. The patients' log books were analysed to check if patients had measured glucosuria at least once per week. The resulting urine tests during the final four weeks were considered for the study. 85.2 % of the patients had previously participated in a structured education programme. According to the results of urine testing for glucose, the patients were divided into three groups: Urine tests always negative, < 50 % of tests positive and ≥ 50 positive. HbA_{1c} results were adjusted to the DCCT standard.

Results: The patients performed 9.8 per urine tests per week (mean, range 1–21). The urine tests were always negative in 57.4% of the patients (HbA1c 6.3 %, min 5.0, max 7.9%; age 63.5 years, time since diagnosis 6.1 years, BMI 31.7). 30.6 % had <50% positive results testing for glucosuria (HbA1c 6.8 %, min 5.5, max. 9.0 %, age 60.9 years, 8.9 years since diagnosis, BMI 29.4) and 12.0% had ≥50% positive result (HbA1c 7.4%, min 6.2, max 9.1%, age 59.7 years, time since diagnosis 6.6 years, BMI 29.5). The frequency of positive SMUG tests had a significant positive correlation with HbA1c ($R^2 = 0.265$, $p < 0.001$).

Conclusion: Patients with diabetes type 2 and without insulin treatment who are negative for postprandial glucosuria have a near normal HbA1c range. There was a strong statistical relationship between the results of urine testing for glucose and HbA1c. Postprandial testing urine tests for glucose are an effective, painless and inexpensive method for metabolic self-monitoring in patients with type 2 diabetes without insulin therapy.

962

Episodic, intensive SMBG in non-insulin-treated T2DM: can this form of patient-provided data be trusted?

W. Polonsky¹, L. Fisher², C. Parkin³, Z. Jelsovsky⁴, R. Wagner⁵;

¹Behavioral Diabetes Institute, San Diego, ²University of California, San Francisco, San Francisco, ³CGParkin Communications, Inc., Las Vegas,

⁴Biostat International, Inc., Tampa, ⁵Roche Diagnostics, Inc., Indianapolis, USA.

Background and aims: In anticipation of an upcoming medical visit, T2DM patients may temporarily “flee to health”, choosing to adhere more closely to medical recommendations. Therefore, one concern about the use of patient-provided SMBG data, especially if the data are restricted to only the few days prior to the appointment, is that these data may not be truly representative of the patient's glycemic status. Given the growing interest in intensive, episodic approaches to SMBG, this is a critical issue, since these data may be used to guide treatment recommendations. How concerned should we be?

Materials and methods: To address this question, we examined data from the Structured Testing Program (STeP), which investigated the impact of structured SMBG use on HbA1c over 12 months. In this prospective, cluster-randomized, multi-centered clinical trial, 483 poorly-controlled (HbA1c ≥7.5%), non-insulin-treated T2DM patients were randomized to structured testing (STG) or active control (ACG). STG subjects used the ACCU-CHEK® 360° View Blood Glucose Analysis System to collect/interpret 7-point glucose profiles over each of 3 consecutive days. They then brought the data to be reviewed with their physician. In this report, we focus only on STG patients ($n = 227$), who completed the tool on a quarterly basis (at months 1, 3, 6, 9 and 12) and shared the results with their physician. HbA1c was also collected at each quarterly visit. STG patients and physicians received standardized instruction in SMBG pattern recognition/interpretation. All patients received free blood glucose meters and test strips.

Results: At each quarterly visit, mean patient-reported blood glucose levels across the 3-day record were highly correlated with HbA1c (month 1, $r = .72$; month 3, $r = .77$; month 6, $r = .68$; month 9, $r = .70$; month 12, $r = .76$; in all cases, $p < 0.0001$). In addition, change in mean, quarterly patient-reported blood glucose levels was significantly associated with change in quarterly HbA1c over the entire 12 months ($r = .75$; $p < 0.0001$). The correlations were not significantly different across age, gender, ethnicity, BMI or diabetes duration.

Conclusion: Intensive, episodic, patient-reported SMBG data, covering three days prior to a quarterly medical visit, are significantly related to overall glycemic control, as assessed by HbA1c. Furthermore, change in these mean episodic SMBG data over 12 months is closely associated with change in HbA1c over the 12 months. These findings suggest that intensive SMBG data accurately reflect overall glycemic control and can be used to adjust treatment without fear of a “flight to health” effect. Indeed, as we have reported previously, the use of such data in the STeP study was found to be associated with a significantly greater long-term glycemic improvement than found among control subjects.

Long-term effects of self-monitoring of blood glucose on glucometabolic control in patients with type 2 diabetes mellitus: follow up data from ROSSO-in-praxi international

K. Kempf^{1,2}, T. Tankova³, S. Martin¹;

¹West-German Centre of Diabetes and Health, Düsseldorf Catholic Hospital Group, Germany, ²Sana Hospital Gerresheim, Sana Clinics Düsseldorf GmbH, Germany, ³Clinical Centre of Endocrinology, Medical University, Sofia, Bulgaria.

Background and aims: As essential risk factors for type 2 diabetes mellitus (T2DM) are obesity, lack of physical activity and high caloric diet, the basis for all therapies should be a lifestyle change. Self-monitoring of blood glucose (SMBG) is a simple tool to visualize the effects of lifestyle change on blood glucose levels in insulin-naïve patients with T2DM. Recently, we could demonstrate by the randomized controlled trial ‘ROSSO-in-praxi international’ that a 12-week SMBG-structured lifestyle intervention improves glucometabolic control of T2DM patients. So far it is unknown if such a short-time intervention also has long-term effects. Therefore, patients were followed for a mean period of 1.5 years.

Materials and methods: 124 SMBG-naïve T2DM ambulatory patients had been randomly assigned to a SMBG ($n=63$) and a control group ($n=61$). Both groups got a manual with basic information about healthy lifestyle. Glucometabolic parameters were assessed at baseline, after 12 weeks and again after 1.5 years and compared using Friedman test + Dunn's multiple comparison test.

Results: During the 12 weeks of intervention participants in the SMBG group significantly improved their HbA1c (from $7.4 \pm 1.6\%$ to $6.9 \pm 1.1\%$; i.e. -0.5% ; $p < 0.001$) and lost weight (-1.0 kg; $p < 0.05$), while HbA1c reduction (from $7.5 \pm 1.0\%$ to $7.3 \pm 1.0\%$; i.e. -0.2%) and weight loss (-0.6 kg) were not significant in the control group. In addition, cardiovascular risk factors such as waist circumference, systolic and diastolic blood pressure, total and LDL cholesterol as well as triglyceride levels significantly improved just in the SMBG group. Patients were followed up for a mean of 1.5 years with 122 out of 124 patients completing the follow up. Interestingly, HbA1c level increased again in the control group, reaching baseline values (i.e. $7.5 \pm 0.7\%$). In the SMBG group improvement of HbA1c ($6.9 \pm 0.9\%$; i.e. -0.5% vs. baseline; $p=0.0003$ for trend) as well as systolic and diastolic blood pressure and lipid parameters maintained stable, while weight (-1.7 kg vs. baseline; $p=0.0003$ for trend), BMI and waist circumference improved further. 87% of participants in the SMBG group continued to perform SMBG. Those who measured their blood glucose $>3x$ per week, demonstrated an overall reduction in HbA1c of 1.0% ($p=0.006$ vs. those who measured at most $3x$ per week) after 1.5 years.

Conclusion: Integration of a short-time, highly motivational and low-cost intervention into basic therapy of T2DM improves glucometabolic health and has long-term effects on glucometabolic control. SMBG might be a motivational tool for lifestyle change. But any benefit will depend on the ability of patients to understand the results and to respond appropriately. Clearly, SMBG may not be useful to patients who lack the necessary skills and motivation for proper documentation and utilization of SMBG results. Therefore, SMBG should be offered to all T2DM patients who are trying to adapt to a healthier lifestyle.

Evidence of a strong association between the frequency of self-monitoring of blood glucose and haemoglobin A_{1c} levels in type 1 diabetes exchange participants

K.M. Miller¹, I.B. Hirsch², R. Beck¹, T1D Exchange Clinical Center Network; ¹Jaeb Center for Health Research, Tampa, ²University of Washington Med Ctr-Roosevelt, Seattle, USA.

Background and aims: American insurance companies have questioned whether or not sufficient evidence is available to justify unlimited coverage of Self-Monitoring of Blood Glucose (SMBG) test strips for patients with type 1 diabetes (T1D). The large database of the T1D Exchange clinic registry provided an opportunity to evaluate the relationship between the number of times SMBG is performed per day and Hemoglobin A_{1c} (HbA_{1c}) levels across a wide age range of children and adults.

Materials and methods: The registry, which currently includes over 50 centers in the U.S., commenced enrollment of children and adults with T1D in September 2010, with longitudinal participant data collected through medical records and participant or parent/guardian of participant (for child participants) questionnaires. SMBG frequency was self reported by 4621 participants who were not using a real-time continuous glucose monitor (CGM) (age range 0 to 91 years, 51% female, 86% non-Hispanic white, mean diabetes duration 11.4 years, 54% using a pump), of whom downloaded meter data were available for 2523 (55%). The analysis assessing the association between SMBG and mean HbA_{1c} was stratified by age group and separately by insulin method (insulin pump and injection) for child (< 18 years old) and adult participants. The 854 participants using CGM were not included in the analyses.

Results: Among the 4621 participants the mean HbA_{1c} was $8.2\% \pm 1.5\%$ and the mean self reported frequency of SMBG measurements was 6 ± 2 per day. Among the 2523 participants with both self reported and downloaded data, the mean self-reported SMBG was 6 ± 2 , where the SMBG from meter downloaded data was 5 ± 3 . A strong association ($P < 0.001$) was present between frequency of SMBG measurements and HbA_{1c} levels, with increasing daily self-reported SMBG frequency being associated with lower HbA_{1c} levels for all age groups [Figure 1]. The same relationship was observed when the analysis was stratified by pump verse injection users separately for child (< 18 years) and adult participants ($P < 0.001$ for all comparisons). Similar strong associations were seen when the meter downloads were evaluated.

Conclusion: Across a wide age range of children and adults, there was a strong linear relationship in which higher daily frequencies of SMBG measurements were associated with lower HbA_{1c} levels. A similar relationship between frequency of SMBG and HbA_{1c} was observed for both injection and pump users for child and adult participants.

Decision support tools improve clinicians' ability to interpret structured SMBG data

O. Schnell¹, H.W. Rodbard², J. Unger³, C. Rees⁴, C. Parkin⁵, Z. Jelsovsky⁶, L. Amstutz⁴, N. Wegmann⁴, M. Schweitzer⁷, R. Wagner⁴;

¹Diabetes Research Institute at the Helmholtz Center, Munich, Germany, ²Endocrine and Metabolic Consultants, Rockville, USA, ³Catalina Research Institute, Chino, USA, ⁴Roche Diagnostics, Inc., Indianapolis, USA, ⁵CGParkin Communications, Inc., Las Vegas, USA, ⁶Biostat International, Inc., Tampa, USA, ⁷Roche Diagnostics GmbH, Mannheim, Germany.

Background and aims: Self-monitoring of blood glucose (SMBG) is useful only when the glucose information is collected in a structured manner, the data are accurately interpreted, and the results prompt appropriate therapeutic actions. The Accu-Chek® 360° View blood glucose analysis system is a simple paper tool that facilitates collection and visualization of 7-point glucose profiles from 3 consecutive days. Using this tool, 78% of clinicians were able to correctly identify the primary glycemic abnormalities. However, only 66.4% of clinicians correctly identified fasting/preprandial hyperglycemia. Utilizing the 360° View tool in a large, cluster-randomized, clinical trial, the STeP study demonstrated significant reductions in HbA_{1c} when structured SMBG is combined with comprehensive clinician education regarding data interpretation and use. We developed an automated decision support tool (DST) for use with the 360° View form. The DST algorithm analyzes SMBG data from the 360° form and generates a printed report that identifies the primary glycemic abnormality and recommends appropriate therapeutic options. We evaluated the impact of the DST on clinicians' ability to identify glycemic abnormalities in SMBG data.

Materials and methods: In this prospective, randomized, controlled, multicenter study, 288 clinicians (39.6% family practice physicians, 37.9% internal medicine physicians, and 22.6% nurse practitioners) were randomized to four study groups: structured SMBG alone (Group A, n=72); structured SMBG with DST (Group B, n=72); structured SMBG with educational DVD (Group C, n=72); and structured SMBG with DST and educational DVD (Group D, n=72). Clinicians were asked to analyze 30 patient cases drawn from the STeP study cohort, identify the primary abnormality, and select the most appropriate class of drug to treat the abnormality. An expert clinician panel reviewed the cases and established correct answers.

Results: 223 clinicians completed all 30 patient cases with no major protocol deviations. Significantly more Group D clinicians (87%) correctly identified the primary glycemic abnormalities than Group A clinicians (51%, $p < 0.0001$), Group B clinicians (77%, $p = 0.0454$) and Group C clinicians (72%, $p < 0.0001$) (Figure 1). Significantly more Group D clinicians (86%) accurately identified preprandial glycemic abnormalities than clinicians in Groups A (47%, $p < 0.0001$) and C (64%, $p < 0.0001$); Groups B and D were not significantly different. Significantly more Group D clinicians (86%) accurately identified postprandial glycemic abnormalities than clinicians in Groups A (55%, $p < 0.0001$) and B (73%, $p = 0.027$); Groups C and D were not significantly different.

Conclusion: The recent STeP study demonstrated the clinical efficacy of structured SMBG when combined with comprehensive clinician education. Addition of the new automated decision support technology (DST) significantly improved the clinicians' ability to accurately interpret structured SMBG data.

Association of self monitoring of blood glucose, medication adherence, and glycaemic control in diabetes patients not using insulin

N.S. Virdi¹, P. Raja¹, M. Daskiran², C. Kozma³, S. Nigam²;

¹LifeScan, Inc, Milpitas, ²Johnson and Johnson, New Brunswick, ³CK Consulting, Saint Helena Island, USA.

Background and aims: There is debate about the value of SMBG in non-insulin type 2 diabetes necessitating further research. The aim of this study was to examine the associations between SMBG presence, medication adherence, and improved glycemic control.

Materials and methods: Medication naïve type 2 diabetes patients, 18-63 years of age, who began non-insulin diabetes therapy (including injectables) between 1 October 2006 through 31 March 2009 were identified using a US commercial insurance claims database (i3 Innovus). Patients were required to have A1C values within the 3 months before and 4-12 months after medica-

tion initiation. A medication possession ratio (MPR) was calculated for each patient. Patients were considered adherent if the MPR $\geq 80\%$. Logistic regression was used to calculate odds ratios for medication adherence. ANCOVA was performed to assess for interactions between SMBG presence, A1c, and medication adherence.

Results: In the 5172 patients, initiation therapies were metformin (69%), sulfonylurea (10%), TZDs (10%), or DDP-4 inhibitors (6%). 2,744 patients (53.1%) had SMBG available post-medication start and 2,428 (46.9%) did not. SMBG presence was associated with a higher likelihood than SMBG absence of being medication adherent (OR 1.5, 95% CI 1.3–1.7). Medication adherent patients had a significantly larger predicted decline in A1c in the post-medication period (-1.35 vs. -0.82 for non-adherent patients, $p < 0.001$). ANCOVA controlling for age, gender, and prior A1c demonstrated a significant interaction among SMBG presence, medication adherence, and baseline A1c ($p < 0.0001$). Higher baseline A1c was associated with greater decline in A1c, post-medication. Both SMBG presence and medication adherence were associated with a similar degree of decrease in A1c. For example, A1c is 9% and other factors are held at mean values, among nonadherent patients the change in A1c was -2.00 for SMBG and -1.36 ($p < 0.0001$) for no SMBG; and for medication adherent patients, -2.37 for SMBG and -2.08 for no SMBG ($p < 0.0001$).

Conclusion: SMBG presence was associated with greater medication adherence. Additionally, SMBG presence was associated with improvement in glycemic control for both medication adherent and non adherent patients. This suggests an association of SMBG presence with glycemic control independent of medication adherence.

PS 084 Continuous glucose monitoring

967

Comparison of patient-led or physician-driven continuous glucose monitoring in poorly-controlled type 1 diabetic patients: a one-year multicenter study

J.-P. Riveline^{1,2}, B. Boucherie¹, C. Peschard³, H. Hanaire⁴, L. Rocher⁵, L. Floch⁶, A. Farret⁷, A. Sola⁸, A. Penfornis⁹, C. Vignon¹⁰, V. Sulmont¹¹, B. Catargi¹², R. Radermecker¹³, G. Charpentier¹, Capteur Evadiac group; ¹Service de diabétologie endocrinologie, Centre hospitalier sud-francilien, Corbeil-Essonne, France, ²UMR-S 872, Cordeliers Research Center, INSERM, Paris, France, ³CERITD, Centre hospitalier sud-francilien, Corbeil-Essonne, France, ⁴Pôle Cardio-Vasculaire et Métabolique, Service de Diabétologie, CHU Toulouse, France, ⁵Service de Nutrition-Endocrinologie-Maladies Métaboliques, University Hospital Sainte Marguerite, Marseille, France, ⁶Institut du thorax, Service d'endocrinologie-diabétologie, CHU de Nantes, France, ⁷Endocrinology Department, Montpellier University Hospital, France, ⁸Service de Diabétologie, CHU Hôtel-Dieu, Paris, France, ⁹Department of Endocrinology, Centre Hospitalier Universitaire de Besançon, France, ¹⁰Service Endocrinologie et CIC, Hôpital Robert Debré, APHP, Paris, France, ¹¹Service de pédiatrie A, American Memorial Hospital, CHU de Reims, France, ¹²Department of Endocrinology, CHU Bordeaux, Pessac, France, ¹³Division of Diabetes, Nutrition and Metabolic Disorders, Department of Medicine, CHU Sart Tilman, University of Liège, Belgium.

Background and aims: Benefits of real-time continuous glucose monitoring (CGM) have been shown in type 1 diabetic (T1D) patients in 3- to 6-month studies. The aim of the present study is to assess the effect of two approaches of one-year use of CGM in poorly-controlled T1D

Materials and methods: The study protocol was designed as a 1-year, multicenter trial. Inclusion criteria were age ≥ 8 yrs, T1D for ≥ 1 year, use of either multiple daily insulin injections (MDI) or an insulin pump and A1c level $\geq 8\%$. Patients were randomly assigned into 3 groups (1:1:1). Two modes of using CGM (FreeStyle Navigator™) were considered: Group 1 (G1): patient-led, Group 2 (G2): physician-driven where sensors were prescribed initially 50% of the time and more often if the targets were not reached (A1c $< 7.5\%$, < 4 mild hypoglycaemia/week, no severe hypoglycaemia). These two strategies were compared to a Self Blood Glucose Monitoring practice (Group 3 (G3): control). The primary outcome was the change in A1c level at one year.

Results: Overall, 178 patients completed the study: age 36 ± 14 yrs, duration of T1D: 17 ± 10 yrs, A1c: $8.9 \pm 0.9\%$, SD glucose (8-point blood glucose profile): $70 [52; 84]$ mg/dl (mean \pm SD or median [95% CI]). At one year, A1c changes were similar in both CGM groups, and significantly higher than in the control group: G1 vs G3: -0.52% , $p = 0.0006$, G2 vs G3: -0.47% , $p = 0.0008$, G1+G2 vs G3: -0.50% , $p < 0.0001$. SD glucose was reduced only in group 2 by $15.7 [-28.8; -4.61]$ vs G3 by $0.6 [-8.9; -4.6]$ mg/dl ($p = 0.049$). Occurrence of hypoglycaemia was similar in the 3 groups. Diabetes Quality of Life questionnaire (DQoL) showed improved patient satisfaction while SF-36 questionnaire pointed out better physical health scores in both CGM groups (respectively $p = 0.004$ and $p = 0.04$). The number of sensors used per month was significantly lower in G2 vs G1: $2.25 [1.27; 2.99]$ vs $3.42 [2.20; 3.91]$, $p < 0.001$. Improvement of A1c level was higher in patients on pump (G1+G2 vs G3: -0.7%) than on MDI (G1+G2 vs G3: -0.2%).

Conclusion: A long-term use of CGM resulted in a sustained improvement of glucose control and QoL in poorly-controlled T1D patients. A CGM prescription by the physician achieved a same improvement as a patient-led use, but with 34% fewer sensors.

Closed-loop glycaemic control over 36 hours in adolescents with type 1 diabetes

J.M. Allen^{1,2}, D. Elleri^{1,2}, K. Kumareswaran¹, L. Leelarathna¹, M. Nodale¹, K. Caldwell¹, H. Murphy¹, M.E. Wilinska¹, C.L. Acerini², D.B. Dunger^{1,2}, R. Hovorka^{1,2}

¹Institute of Metabolic Science, ²Department of Paediatrics, University of Cambridge, Cambridge, UK.

Background and aims: We evaluated closed-loop (CL) insulin delivery during a 36-hour period replicating normal daily activities.

Materials and methods: Twelve adolescents with type 1 diabetes mellitus (T1D) (M 5; age 15.0±0.9 years; A1C 7.9±0.7%; BMI 21.4±2.6 kg/m²; duration of diabetes 6.1±2.8 years; total daily dose 1.0±0.4 U/kg/day; mean±SD) were studied at a clinical research facility on two occasions. Subjects were randomly allocated to receive either CL or open-loop (OL) (conventional CSII treatment) from 19:30 on day 1 for 36 h. During CL, basal rates on insulin pump were manually adjusted every 15 min as per advice of a model-predictive-control algorithm informed by real-time continuous glucose monitor. On each occasion, subjects engaged in normal daily activities (e.g. playing computer games, walks). They consumed meals (50–80 g CHO), accompanied by self-calculated insulin boluses, and snacks (15–30 g CHO). Moderate-intensity exercise on a stationary bicycle at 140 bpm heart-rate was performed at 10:40 (40 min) and at 17:30 (20 min).

Results: Overall mean plasma glucose levels were 7.2±1.2 mmol/l during CL versus 9.0±2.9 mmol/l during OL ($p=0.009$). Time spent in target glucose range 3.9–10 mmol/l was 82±10% vs 55±29% ($p=0.002$). Time above 10 mmol/l was 13±12% vs 37±33% ($p=0.005$) and time spent below 3.9 mmol/l was 5±4% vs 7±11% ($p=0.50$). Overnight, plasma glucose levels were in target for 97±7% vs 51±38% ($p=0.02$) and for 95±11% vs 45±45% ($p=0.001$) during the first and second night, respectively. Hypoglycaemia occurred on 11 occasions during OL vs 9 during CL (5 episodes were exercise-related, 4 occurred within 2 hours after meals).

Conclusion: Day-and-night CL may improve glucose control significantly compared to conventional CSII. Further adjustments are needed to optimise insulin delivery to minimise risk for hypoglycaemia after exercise and around meals.

Figure. Plasma glucose levels (median, IQR) during closed-loop (black line) and open-loop (grey line) over the 36 h study period. Closed-loop started at 19:30 (vertical black line). Exercise sessions are shown by grey shadows. Vertical arrows illustrate when main meals (M) and snacks (S) were given.

Real time glucose monitoring system in patients with type 1 diabetes mellitus: systematic review and meta-analysis

A. Ramotowska¹, D. Golicki², K. Dzygala¹, A. Szybowska¹

¹Pediatric Department, ²Department of Pharmacoeconomics, Medical University of Warsaw, Poland.

Background and aims: It's well known that tight metabolic control is crucial to prevent complications in type 1 diabetic (T1DM) patients. Conventional self blood glucose monitoring (SMBG) with glucose meter does not reflect the fluctuation of glucose level precisely enough. Continuous glucose monitoring system (CGMS) enables measurements in every 5 minutes, which provides more accurate data and can reduce the fear of hypoglycemia. Previous meta-analysis of randomized controlled trials (RCTs) using CGMS in a

retrospective way compared with SMBG did not show significant reduction in HbA1c in T1DM patients. Recently, several studies, many of them observational, have assessed the effect of real time CGMS (RT-CGMS) on metabolic control of type 1 diabetic patients. The results of the studies differed: a number of them have demonstrated a reduction in HbA1c with the RT-CGM, the other have not confirmed any benefits or noted that the benefit associated with continuous glucose monitoring was strongly related to age. Thus, the aim of this study was to explore the potential beneficial effects of the use of RT-CGM on diabetes management when compared with SBGM in patients with type 1 diabetes by conducting a systematic review and meta-analysis of randomized controlled trials.

Materials and methods: MEDLINE, EMBASE and The Cochrane Library were searched by two independent investigators for RCTs relevant to use RT-CGMS in patients with T1DM; additional references were obtained from the reviewed articles.

Results: 12 RCTs (n=1750 participants) met the inclusion criteria. Combined data from all studies showed better HbA1c reduction in subjects using RT-CGMS compared with SMBG (mean difference (MD) - 0.43; 95% CI: - 0.59 to - 0.27; $p<0.001$). The improvement in glycaemic control was observed in subjects treated with sensor-augmented insulin pump compared to both multiple daily injections or conventional insulin pump (8 RCTs, n=1075, MD - 0.51; 95% CI: - 0.76 to - 0.27; $p<0.001$). The beneficial effect of the real time CGM was observed in diabetic adults (n= 646, MD - 0.59; 95% CI: - 0.87 to - 0.31; $p<0.001$), as well as children (n= 464, MD - 0.34; 95% CI: - 0.52 to - 0.16; $p<0.001$). The reduction in HbA1c was noted in both groups with excellent or poor controlled type 1 diabetes. The benefits of applying the real-time CGM were not associated with increasing rate of acute hypoglycaemia.

Conclusion: Our meta-analysis confirmed that the use of the real time-CGMS compared with self-monitoring of blood glucose effectively lowers HbA1c in type 1 diabetes patients treated with continuous subcutaneous insulin infusion or multiple daily injections. The real-time CGMS is beneficial not only for people with poor diabetes control but also for well controlled diabetic patients. The use of this method improved glycaemic control both in adults and children, with type 1 diabetes.

970

Successful transitions from MDI therapy to sensor-augmented pump therapy in the STAR 3 study: system settings and behaviours

S.W. Lee¹, J.B. Welsh¹, J.B. Green², C. Joyce³, W.V. Tamborlane⁴

F.R. Kaufman¹

¹Medtronic Diabetes, Northridge, USA, ²Division of Endocrinology, Metabolism, and Nutrition, Duke University Medical Center, Durham, USA, ³Memorial University of Newfoundland, St. John's, Canada, ⁴Yale Center for Clinical Investigation, Yale School of Medicine, New Haven, USA.

Background and aims: To successfully initiate sensor-augmented pump (SAP) therapy, appropriate initial settings for the insulin pump and the continuous glucose monitoring (CGM) subsystems are important. Subjects who realize rapid initial A1C reductions may employ different pump settings or adjustment strategies than subjects with minimal A1C reductions during the first 3 months after switching from MDI to SAP.

Materials and methods: The STAR 3 trial randomized 485 suboptimally-controlled subjects on multiple daily injection (MDI) therapy to either receive SAP therapy (n=244) or MDI therapy (n=241) for 1 year. At the end of the randomized phase, MDI subjects (n=204) entered the continuation phase of the study and switched to SAP therapy for 6 months and SAP subjects (n=216) continued on SAP. Subjects were grouped according to age, randomization assignment, and their A1C value after the first 3 months of SAP therapy (ie, month 3 for SAP subjects and month 15 for MDI subjects who switched). Pairwise comparisons between subjects in the highest and lowest A1C quartiles were made via t-test; significance of trends across all A1C values was evaluated via linear regression.

Results: Most subjects chose to continue with (89%) or switch to (85%) SAP therapy at 12 months. Subjects with the lowest A1C values 3 months after SAP initiation had lower baseline A1C values. These subjects consistently had lower glycemic variability (SD of CGM values) than subjects with higher A1C values. Subjects with the highest A1C values averaged fewer daily boluses, used the Bolus Wizard calculator less often, and wore CGM sensors less frequently than subjects with the lowest A1C values after 3 months on the pump. These results held for subjects who began SAP therapy at the beginning of the study and for those who switched to SAP therapy after 12 months in the MDI arm of the study. Among the 204 MDI subjects who switched, those with the lowest A1C values after 3 months of SAP therapy had adjusted their basal in-

sulin delivery rates more than twice as often as subjects with the highest A1C values. The trends and pairwise differences were not statistically significant across all 4 patient subgroups (Table).

Conclusion: Successful transitions of patients from MDI to SAP therapy, as assessed by A1C values after 3 months of SAP use, are associated with frequent use of CGM sensors, frequent bolus dosing, smaller bolus doses, and greater use of the Bolus Wizard calculator compared to patients who realize only modest A1C improvements in the initial 3 months of pump therapy. For subjects who have attempted optimal management with MDI, favorable initial decreases in A1C with SAP therapy may be associated with frequent changes to the pump's basal insulin delivery rate.

Comparison of subjects after 3 months SAP therapy.

Influence of time-point of calibration on accuracy of a continuous glucose monitoring system

T. Zueger, I. Krull, S. Mougiakakou, P. Diem, C. Stettler;
Division of Endocrinology, Diabetes and Clinical Nutrition, Bern, Switzerland.

Background and aims: Currently used continuous glucose monitoring systems (CGMS) need to be calibrated by self measured blood glucose (SMBG) values. Data on the influence of the time-points of calibration on accuracy of CGMS is scarce. In general, calibrations are recommended during stable glycaemia and, therefore, essentially in fasting or pre-prandial situations. However, in clinical practice the possibility of less strict calibration modes (including post-prandial SMBG) may improve adherence of patients. The aim of the present study was to investigate whether the pattern of calibration (predominantly pre-prandial vs. predominantly post-prandial) has an influence on sensor accuracy and whether this effect differs according to the glycaemic level.

Material and methods: Twenty individuals with type 1 diabetes (mean \pm SEM age 35.9 \pm 2.9 years, HbA_{1c} 7.3 \pm 0.3 %, diabetes duration 17.2 \pm 2.1 years) were included into the study. Two CGMS Guardian-RT[®] (Medtronic, Minneapolis, USA) were applied simultaneously with sensors inserted into the lower abdomen on either side. One sensor was calibrated predominantly using pre-prandial SMBG (Calibration_{PRE}: two preprandial values and one bedtime value). The other sensor was calibrated predominantly using post-prandial SMBG (Calibration_{POST}: two postprandial values and one fasting value). The bedtime value in Calibration_{PRE} and the fasting value in Calibration_{POST} had to be included due to technical requirements of the CGMS system. A minimum of 3 additional SMBG per day were obtained for analysis of accuracy. Sensor readings of each calibration pattern were divided into 4 categories according to the glycaemic range of the reference values (low \leq 4 mmol/l; euglycaemic 4.1–7 mmol/l; hyperglycaemic I 7.1–14 mmol/l and hyperglycaemic II $>$ 14 mmol/l).

Results: The overall mean \pm SEM absolute relative difference (MARD) between capillary reference values and sensor readings was 18.3 \pm 0.8% for Calibration_{PRE} and 21.9 \pm 1.2% for Calibration_{POST}, respectively ($p < 0.001$). MARD according to glycaemic range was 47.4 \pm 6.5% (low), 17.4 \pm 1.3% (euglycaemic), 15.0 \pm 0.8% (hyperglycaemic I), and 17.7 \pm 1.9% (hyperglycaemic II) for Calibration_{PRE} and 67.5 \pm 9.5% (low), 24.2 \pm 1.8% (euglycaemic), 15.5 \pm 0.9% (hyperglycaemic I), and 15.3 \pm 1.9% (hyperglycaemic II) for Calibration_{POST}, respectively ($p < 0.001$ for difference within subgroups for both calibration patterns). In low and euglycaemic ranges MARD was significantly lower in

Calibration_{PRE} compared with Calibration_{POST} ($p = 0.007$ and $p < 0.001$, respectively).

Conclusions: Sensor calibration predominantly based on pre-prandial SMBG resulted in a significantly higher overall sensor accuracy compared with a predominantly post-prandial calibration. The difference is most pronounced in the hypo- and euglycaemic reference range whereas both calibration patterns were comparable in the hyperglycaemic range.

972

Prognosis of diabetes related complications by continuous glucose monitoring profiles: data of the JDRF study analysed by the glucose-pentagon-model

A. Thomas¹, L. Heinemann²;

¹Medtronic, Meerbusch, Germany, ²Science&Co., Düsseldorf, Germany.

Background and aims: Variability in glycaemia in patients with diabetes can be documented by means of continuous glucose monitoring (CGM) but not with capillary self-monitoring of blood glucose or HbA1c measurement. The glucose pentagon model (GPM) takes four parameters obtained by analysis of CGM recordings beside the HbA1c into account. By doing so a risk parameter (GRP) derived from the GPM might allow a better prognosis of the risk to develop diabetes related complications (DRCs) than the HbA1c by taking variability parameters into account.

Materials and methods: Data from 108 patients from the JDRF study (Medtronic CGM-System only) were analyzed: CGM profiles from the start of the study and after 6-month were analysed by a software that generates the GPM and calculates the GRP. The change in this risk parameter was compared to the risk indicated by the change in HbA1c.

Results: The improvement in HbA1c from 7.4% to 7.0% during this study was accompanied by a reduction in mean glucose (from 163 to 156 mg/dL), standard deviation (61 to 57 mg/dL), AUC $>$ 160 mg/dL (29.2 to 23.1), and time per day $>$ 160 mg/dL (634 to 576 min). The reduction in a risk parameter calculated from the GPM from 3.3 to 2.7 by 18.2% was larger than the risk reduction by 8.6% indicated by the HbA1c.

Conclusion: In summary, the prognosis for the development of DRCs by using the GPM appears to be more valid than that provided by the HbA1c. Long-term studies will more definitively proof that parameters describing variability in glycemia should be part of such risk parameters. (We would like to thank the JDRF for providing us the data for this analysis.)

973

Glucose sensor performance during pressure changes

J. Jendle¹, P. Adolffson², H. Ornhagen³, R. Shah⁴, K. Cooper⁴, R. Gautham⁴;
¹Endocrine and Diabetes Center, Karlstad Hospital and Faculty of Health Sciences, Orebro, Sweden, ²Pediatrics, Institute for the Health of Women and Children, The Sahlgrenska Academy at Gothenburg University, Goteborg, Sweden, ³Swedish Sports Diving Federation, Farsta, Sweden, ⁴Glucose Sensor R&D, Medtronic Diabetes, Northridge, USA.

Background and aims: There is a need to provide people with diabetes a reliable device that continuously measures glucose in hypo- and hyperbaric conditions as during SCUBA diving when 30 meter depth corresponding to

4 atm and in commercial aircrafts with a cabin pressure of 0.75 atm. The aim of this study was to test Medtronic's new Enlite glucose sensor in hypobaric and hyperbaric environments, providing evidence that sensor performance is acceptable.

Materials and methods: This feasibility study was conducted in a pressure chamber. A non-diabetic subject was chosen to be studied allowing for non-glucose specific changes in signal to be evaluated. Half of the sensors were pre-wetted with sterile saline prior to subcutaneous insertion. On Day 1 of the study, the subject had 24 Enlite glucose sensors inserted (right side of the body, 12 abdominal and 12 lower back), with the lower back sensors being pre-wetted. After the 2 h sensor initialization period and a stabilization period at 1.0 atm, the chamber pressure was ramped down to 0.5 atm (~10 kPa O₂) for a period of 20 min, raised to 0.75 atm (~16 kPa O₂), and then returned to 1.0 atm (21 kPa O₂). During this time, frequent blood glucose samples were taken via Hemocue blood glucose monitor every five minutes. On Day 2 of the study, the subject was again inserted with 24 Enlite glucose sensors (left side of the body, 12 abdominal and 12 lower back), with the abdominal sensors being pre-wetted prior to insertion. After 2 h initialization, the chamber pressure was increased to 4.0 atm (~84 kPa O₂) for a period of 20 min, followed by a decompression to 1.0 atm. During the exposure to varying pressures, a parallel in-vitro test was run using eight Enlite sensors connected to a 1-min Medtronic iPro and eight Enlite sensors connected to a 5-min MiniLink linked to a Guardian receiver.

Results: The in-vivo/vitro signals and blood glucose values were processed to mimic what a user of a Medtronic CGM device would see in real-time. On Day 1, a total of 266 paired sensor/meter points were collected in-vitro yielding an overall MARD of 14.9%, with 100% being in the Clarke A+B region. Although the analysis of the sensor sensitivity showed a slight decrease ($p < 0.05$) during hypobaric conditions, the change was well within the sensitivity thresholds of 1.5–15 as defined by the real-time device. On Day 2, a total of 339 paired sensor/meter points were collected, yielding an overall MARD of 6.69%, with 100% being in the Clarke A+B region. Analysis of the sensor sensitivity showed no significant change in sensor sensitivity ($p = 0.20$). Results from the in-vitro test under the same conditions demonstrated linearity (R^2) of 0.98. There was no significant change in sensitivity during hyperbaric conditions ($p = 0.18$) but there was a change during hypobaric conditions ($p < 0.05$), however the sensitivity was well within the sensitivity thresholds of 1.5–15 as defined by the real-time device.

Conclusion: The results from this feasibility study demonstrate that use of the Medtronic Enlite sensor under hypobaric and hyperbaric conditions showed robust sensor and system performance. Further studies on type 1 diabetic subjects are needed under the same pressure conditions.

974

INTERPRET, an international report on routine practice of sensor-enabled pump therapy: result from the 6 months interim analysis

K. Nørgaard¹, A.E. Scaramuzza², N. Bratina³, N.M. Lalić⁴, P. Jarosz-Chobot⁵, G. Kocis⁶, R. Verkauskienė⁷, C. De Block⁸, O. Carrette⁹, J. Castañeda¹⁰, O. Cohen¹¹, INTERPRET study group;

¹Hvidovre Hospital, Denmark, ²Luigi Sacco Hospital, Milano, Italy, ³UMC-University Children's Hospital, Ljubljana, Slovenia, ⁴Clinic for Endocrinology, CCS, Belgrade, Serbia, ⁵Specjalistyczna Praktyka Lekarska, Gliwice, Poland, ⁶Péterfy Hospital, Budapest, ⁷Kaunas University Hospital, Lithuania, ⁸Antwerp University Hospital, Belgium, ⁹Medtronic International Trading Sàrl, Tolochenaz, Switzerland, ¹⁰Medtronic Bakken Research Center, Maastricht, Netherlands, ¹¹Chaim Sheba Medical Center, Tel Hashomer, Israel.

Background and aims: Randomized controlled trials (RCT) have shown significant reduction in HbA1c with use of continuous glucose monitoring (CGM) combined to insulin pump in type 1 diabetes (T1DM) treatment. In these RCT, sensor usage frequency was shown to impact on the clinical outcomes. The aim of this study is to document the international routine practice in sensor usage in T1DM patients treated with sensor-augmented pump (SAP) therapy. We assess if variables such as frequency of sensor usage, age, HbA1c, and main indication to start CGM are associated with an improvement in clinical outcomes and observe which individuals are benefiting the most from the SAP therapy.

Materials and methods: This international multi-center prospective observational study was conducted in adults and children with T1DM treated by insulin pump therapy for more than 6 months at the time of enrolment and whose physicians decided to treat with SAP. Twenty five clinics from 15 countries participated to the data collection. Patients were followed up for 1 year

and clinical outcomes were assessed every 3 months. An interim analysis is performed on the 6 months follow-up data.

Results: 263 T1DM patients (mean age: 28.0 ± 15.7 years [range 1–69]; BMI: 23.3 ± 4.9 kg/m²; diabetes duration: 13.9 ± 10.7 years and 38% male and 62% female) were eligible for data analyses. Mean HbA1c at baseline was $8.1 \pm 1.4\%$ and 82% of the patients had suboptimal HbA1c $> 7\%$. After 3 months of treatment, the HbA1c change was significantly correlated to sensor usage (Spearman correlation coefficient 0.128; $p = 0.046$) in the overall population. Factors associated with improvement in HbA1c after 6 months of treatment were high HbA1c levels at baseline ($p < 0.0001$), more frequent sensor use ($p = 0.021$) and age group ($p = 0.016$). As shown in the figure 1, the use of sensors was higher in young children (0–7y) and adults ($> 24y$), and the improvement in HbA1c in these groups from baseline was better than in the other age groups, 0.37% and 0.27%, respectively.

Conclusion: This is the first, large observational study providing data from real life practice that shows that initial baseline HbA1c levels, sensor usage compliance and age are significantly associated with reduction of HbA1c levels after 6 months of treatment. Longer-term data will provide further insights as to the clinical practices and outcomes of CGM treatment in real-life.

Long-term continuous subcutaneous insulin infusion systems in daily clinical practice: effectiveness and safety

R. Guerrero Vázquez, M. Martínez-Brocca, D. Acosta Delgado, A. Pumar Lopez, F. Losada, M. Mangas-Cruz, F. Relimpio Astolfi, A. Pérez-Morales, E. Navarro;
Endocrinology and Nutrition, Virgen del Rocio University Hospital, Seville, Spain.

Background and aims: The aims of this study are: 1) to examine the clinical effectiveness of continuous subcutaneous insulin infusion (CSII) systems over a 5-year follow-up period in type I diabetic patients. We will consider the overall clinical situation and the main cause for the patient's indication. 2) assess CIIS safety.

Materials and methods: We performed a descriptive, observational study including all CSII patients until January 2011. We analysed the glycated haemoglobin controls (HbA_{1c}) at the start of therapy and post-CSII at: 1 month, 3 months, 6 months, and every year for 5 years. We examined the following CSII-related complications: hyperglycaemic crises (ketotic, non-ketotic and ketoacidotic [KAD]), local problems (abscesses and lipodystrophies) and severe hypoglycaemic crises.

Results: We attended to 149 type 1 diabetic patients (35 men and 114 women) treated with CSII over an average of 3.59 ± 2.92 years. CSII was implanted for the following reasons: 49 (33%) gestational diabetes, 43 (27%) poor chronic glycaemic control, 40 (29%) glycaemic instability or unstable diabetes, 6 (4%) unnoticed hypoglycaemia, 2 (1%), dawn phenomenon, and 9 (6%) were indicated for several causes. Initial HbA_{1c} was $8.40 \pm 1.28\%$, which decreased to a minimum of $7.17 \pm 1.04\%$ three months after therapy was started ($P < .05$) and remained low at four years follow-up ($7.51 \pm 0.99\%$ [$P < .05$ versus baseline HbA_{1c}]). CSII subgroups: the group with poor metabolic control had a baseline HbA_{1c} of $8.99 \pm 1.29\%$ which decreased after 3 months to $7.39 \pm 1.35\%$ ($P < .05$). This decrease was maintained over 2 years ($7.34 \pm 0.94\%$; $P < .05$ versus baseline HbA_{1c}). The unstable glycaemic group's pre-implantation HbA_{1c} was $8.16 \pm 0.92\%$, which decreased to $7.18 \pm 0.73\%$ after 3 months ($P < .05$) and $7.34 \pm 0.89\%$ at 6 months ($P < .05$ versus baseline HbA_{1c}). We observed 6 severe local problems at the catheter insertion site (2 abscesses that required drainage and 3 partial lipodystrophies) and 32 hyperglycaemic crises, 16 of which were KAD, resulting in a KAD incidence of 0.039 episodes/patient/year. The incidence of severe hypoglycaemic crises was 0.017/patient/year.

Conclusion: 1) CSII therapy improved glycaemic control for the first 4 years of follow-up. We have observed differences in the reduction of HbA_{1c} in the group with glycaemic instability or unstable diabetes at 6 months, and in the poor control group at 2 years. 2) CSII treatment was safe. Catheter-related local complications have been infrequent and the incidence of KAD and hypoglycaemic crises is similar to those reported in other studies.

976

Insulin pump therapy may be equally effective in elderly and young type 1 diabetes patients

T. Klupa, B. Matejko, K. Cyganek, B. Kutra, D. Galicka-Latała, M. Grzanka, M.T. Malecki;
Department of Metabolic Diseases, Jagiellonian University, Krakow, Poland.

Background and aims: It is generally accepted that in type 1 diabetes (T1DM) continuous subcutaneous insulin infusion (CSII) via a personal pump is more effective than the multiple daily injections (MDI) model. It is not clear, however, whether all age groups of adult T1DM patients may equally benefit from CSII therapy. Especially, the effectiveness of this new technology-based therapy in elderly patients may be of concern.

Materials and methods: We aimed to compare the glycaemic control and use of selected pump tools in T1DM patients on CSII over the age of 50 (50+ T1DM) with younger subjects. The last available insulin pump/blood glucose meter downloads and last available HbA_{1c} level of 102 adult T1DM subjects on CSII treatment were reviewed. We have divided our population into 2 subgroups: 50+T1DM patients ($n=10$, mean age: 57.3 ± 7.16 years, duration of diabetes: 24.11 ± 8.05 years, duration on CSII: 6.01 ± 4.19 years) and younger individuals: ($n=92$, age: 26.39 ± 7.71 years, duration of diabetes: 12.41 ± 7.1 years, duration on CSII 3.93 ± 2.75 years).

Results: There were no differences in glycaemic control achieved with CSII treatment by 50+ T1DM patients vs. younger subjects: the HbA_{1c} levels were $6.98 \pm 1.04\%$ and $7.13 \pm 1.16\%$ ($p=0.67$), the mean glycemia based on glucometer downloads was 139 ± 29 mg/dL and 142 ± 36 mg/dL ($p=0.55$), respectively. Interestingly enough, there were no differences with respect to the use of important personal pump options and tools such as daily number of boluses, basal/bolus ratio, frequency of usage of dual-wave/square bolus function and bolus calculator option, percentage of patients using continuous glucose monitoring. 50+ T1DM individuals required more insulin per kilogram (0.71 j/kg vs. 0.56 j/kg for older and younger individuals, respectively, $p=0.036$).

Conclusion: In conclusion, insulin pump therapy can be equally effective in T1DM patients older than 50 and in younger adult subjects with this disease.

977

Quality of life and subcutaneous ambulatory insulin pump in type 2 diabetes patients

J.-P. Courrèges¹, J.-P. Donnet², S. Clavel³, T. Gabreau⁴, D. Gouet⁵, E. Verlet⁶, E. Cosson⁷, P. Jan⁸, B. Cirette⁹;

¹Centre Hospitalier Général de Narbonne, ²University Hospital, Pointe à Pitre, Guadeloupe, ³General Hospital, Le Creusot, ⁴Hospital Center, Auxerre, ⁵Hospital Center, La Rochelle, ⁶Hospital Center, Dunkerque, ⁷University Hospital, Bondy, ⁸Hospital Center, Bar le Duc, ⁹Dinno Sante, Bussy St Georges, France.

Background and aims: Does an insulin pump therapy in diabetic patients provide, beside a better metabolic control, an increase in quality of life, while remaining easy to use?

Materials and methods: 189 Type 2 diabetes patients (age: 58.5 ± 10.2 yrs, sex ratio M/F: 0.4, diagnosed for diabetes for 17.5 ± 9.1 years, weight: 93.3 ± 19.3 kg) switched to an ambulatory subcutaneous insulin pump therapy (glucose control failure in despite of 3.22 ± 1.46 insulin injections/day) are analyzed in an observational study. 139 patients went on with their insulin pump; 8.3% gave up with the pump and among the 139 patients followed after 1 year (T1Y), 90 (65%) have agreed to answer and filled in a Quality of Life questionnaire.

Results: The pumps that were used are of the following types: Accu check spirit (9%), Animas (8%), Cozmo (18%) and Medtronic (65%), and the most used Catheter was ($n=59-51\%$) the QUICK SET type. The analysis on the patient's feeling towards the pump can be classified in: poor - medium - good and concerns: the estimate of general state, the limitation in physical activity and everyday life and the moral state. At T0, only 3.3% of the patients view their general state as good, 67.8% as medium and 28.9% as poor. The physical activity status and everyday life is considered as good by 29.4% of the patients, medium by 44.6% and poor by 26.1%. Regarding the moral status, 31.5% consider it as good, 60.9% medium and 7.6% poor.

Conclusion: The metabolic optimisation through insulin s /c pump after poor glucose corol in despite multi insulin injections treatment, lead, in a large majority of type 2 diabetes patients, to a great improvement of quality of life, with better physical and moral health. Almost all considers the use of the pump is simple. They are satisfied to a better experience and better control thanks to the latter.

Health status and pump (after 1 year)			
	Easy	~ Easy	Difficult
Pump therapy after 1 year, the analysis of the feeling towards the pump: learning and usage ease	58.6%	36.2%	5.2%
Evolutionary feeling of the health status	76.4%	16.4%	7.3%
	Yes	Better	Bad
Efficacy provided by the pump on glycaemic status	45.5%	52.7%	1.8%
	Very good	~ Good	Bad
Feeling and usage towards the pump	74.1%	19.0%	6.9%

978

Continuous subcutaneous insulin infusion is relevant in reducing insulin requirement in patients with type 1 diabetesE. Pankowska¹, M. Błazik¹, L. Groele²;¹Pediatrics, Institut of Mother and Child, ²Pediatrics, Medical University of Warsaw, Poland.

Background and aim: Continuous subcutaneous insulin infusion (CSII) is an alternative to multiply daily injection (MDI) method of insulin delivering in type 1 diabetes patients. In numerous studies has been proofed that CSII reduced the risk of sever hypoglycemia, improve of metabolic control and quality of life in short and longer time of observations. We are still lack of evidences on the efficiency of this method in the term of individual insulin requirement. The aim was to assess the insulin requirement in total (TDDir) and basal daily dose (BDDir) in CSII comparing to MDI method of insulin delivering.

Material and method: The parallel, day-to-day study compared MDI to CSII enrolled 41 pediatrics patients in age 1,3 to 17,9 ys and diabetes duration from 0,01 to 12,7ys and median HbA1c 7,3 from 6,0 to 12,8%. 15 patients in MDI used long action analogues (LAA) and 23 NPH insulin (SAA), 3 patients left without basal insulin; 31 short acting analogues and 10 regular insulin.

Results: The insulin requirement was reduced by 28% in basal and total daily insulin dose. Analysis by the age of patients showed the highest reduction in TDDir by 37% ($p<0,005$) in the youngest group of patients aged 0-7ys. The significant reduction of BDDir by 45% was in children aged 7-12 and by 31% in children above 12 ys. Moreover, lower but not significantly glycemia profile (med. 120,5 mg/dl vs 130,5 mg/dl; $p=0,4$) occurred in CSII method. Considering the type of basal insulin in MDI method reduction by 15% ($p=0,51$) was in LAA group and by 47% in NPH group ($p=0,002$).

Conclusions: CSII method has an impact on reduction in total and basal daily insulin requirement. In the algorithm of introducing CSII method, the reduction of TDD -MDI by 30% should be considered, particularly in pre-schoolers and in patients used NPH insulin.

979

Measures of oxidative stress and anti-oxidant capacity in plasma samples from patients with type 2 diabetes before and after insulin pump therapyS.J. Setford¹, H. Anhalt¹, I. Megson³, J.P. Frias², A. Treweek³;¹Research & Development, LifeScan Scotland Ltd, Inverness, UK, ²Animas Corporation, West Chester, USA, ³UHI Millenium Institute, Inverness, UK.

Background and aims: A cohort of 56 poorly controlled (A1C $8.4\pm1.3\%$) insulin pump-naïve patients consisting of three groups (two or more oral anti-diabetes agents [OADs]; basal insulin with or without OADs; basal-bolus insulin with or without OADs) was subject to a 16 week multi-centre pilot study of insulin pump therapy.

Materials and methods: All diabetes medications except for metformin were discontinued on initiation of pump therapy. Most patients were managed with 1 or 2 basal rates with resultant mean A1C improvement of $1.2\pm1.2\%$ ($P<0.001$). A number of serum biomarker species were determined at initiation and termination of the study including: A1C; insulin; pro-insulin; a measure of antioxidant capacity (oxygen radical antioxidant capacity, ORAC); and measures of oxidative stress (oxidised low density lipoprotein, ox-LDL; protein carbonyls; malondialdehyde, MDA)

Results: Consistent with our hypothesis that improvement in glycemic control using insulin pump therapy in these subjects would result in decrease of these markers, levels of insulin, pro-insulin and oxidative stress markers were depressed by ~10-35% (Table), as compared to baseline. A ~4% depression in ORAC was also observed, a measure that would be expected to increase in the face of reduced oxidative stress. Whilst samples were collected in the fasting state the role of dietary influences cannot be ruled out.

Conclusion: This 16 week pilot study using insulin pump therapy in poorly controlled patients with type 2 diabetes demonstrated markers of oxidative stress and anti-oxidant capacity to decrease, potentially decreasing mediators of inflammation and atherogenesis, in individuals with type 2 diabetes. Future studies should consider measures of endothelial function, coupled with a mechanistic approach to establish the relationship between insulin pump therapy and oxidative stress and to determine if the reduction in glycemia, as indicated by A1C reduction, is the main driver of the observed decrease in oxidative stress markers.

Marker	Change (%)	P
Insulin (pM)	-22.7	0.036
Proinsulin (pM)	-35.4	0.024
MDA (μ M)	-19.4	<0.0001
ORAC (μ IU/mL)	-3.9	0.013
Protein carbonyls (nmol/L)	-15.1	<0.0001
Ox-LDL (U/I)	-10.5	0.033

Long term follow-up in children and adolescents with type 1 diabetes using insulin pump therapy: a retrospective multicentre, multinational study (Input(log) Study)C. Mameli¹, A.E. Scaramuzza¹, J. Ho², R. Cardona-Hernandez³, L. Suarez-Ortega³, G. Zuccotti¹;¹Paediatrics, University of Milano - Luigi Sacco Hospital, Italy, ²Paediatrics, Faculty of Medicine, University of Calgary, Calgary, Canada, ³Endocrinology and Diabetes, Sant Joan de Déu Hospital, Barcellona, Spain.

Background and aims: Few data are available regarding long term follow up in children and adolescents with type 1 diabetes (T1DM) using continuous subcutaneous insulin infusion (CSII). The aim of this study was to evaluate the long-term glycaemic control in children and adolescents with T1DM, using CSII for at least 4 years in three Diabetes Centres from 3 different countries: Italy, Canada and Spain.

Materials and methods: Each centre participating in the study reviewed charts of patients with T1DM, using CSII. Inclusion criteria to enrol patients were: age 4 to 20 yrs., T1DM for more than 4 yrs. and CSII therapy for at least 4 yrs. Data collected included gender, age, T1DM duration, date of CSII initiation, body mass index (BMI), HbA1c, insulin requirement at baseline and every 6 months, and DKA and severe hypoglycaemic episodes at baseline and during follow-up.

Results: After reviewing the charts, 126 patients fulfilling the inclusion criteria were found. Twenty-five of them were excluded because of data missing. We present the data of 101 patients (61 males), aged 4-20 yrs. (mean: 14.6 ± 3.8 yrs.), with T1DM from 9.7 ± 3.3 yrs., using CSII for 5.6 ± 1.7 yrs. (range 4-11 yrs.). HbA1c data are shown in the table. After CSII initiation HbA1c showed a significant improvement only in the first year. During the follow-up, HbA1c values tended to increase. Evaluating HbA1c according to Countries, a difference has been observed with slightly lower values in Italy than in Canada and Spain. When evaluated as a whole group or by Countries, no significant differences were observed for BMI, insulin requirement, severe hypoglycaemia and DKA episodes from baseline throughout the follow-up.

Conclusion: CSII therapy seems an effective therapy in the long term, although the major benefit in HbA1c is seen in the first year of CSII initiation. In this preliminary study, a difference in HbA1c during long term follow-up was observed among Countries. Further studies will evaluate which factors may be responsible for this observation (i.e., different dietetic habits, lifestyle, etc.). Table - HbA1c values according to Country and as a whole. T=time; significance among groups has been evaluated by Kruskal Wallis test: * $p=0.03$; * $p=0.003$; when evaluated as a whole HbA1c has been evaluated using paired test statistic vs. baseline: § $p=0.005$; ° $p=0.005$

	Baseline	T +6mo	T +12mo	T +24mo	T +36mo	T +48mo	T +60mo	Last visit

The low glucose suspend function in sensor-augmented pump therapy prevents hypoglycaemia in children

M. Holder¹, O. Kordonouri², H. Haberland³, S. Golembowski³, S. Zierow³, K. Remus², S. Blasig², T. Waden¹, R. Hartmann², A. Thomas⁴, T. Danne²; ¹Olga Hospital, Stuttgart, ²Kinderkrankenhaus auf der Bult, Diabetes-Zentrum für Kinder und Jugendliche, Hannover, ³SANA Klinikum Lichtenberg, Berlin, ⁴Medtronic Germany, Meerbusch, Germany.

Background and aims: The sensor-augmented insulin pump (SAP) "Paradigm VEO" system offers a novel automatic insulin shut-off mechanism low glucose suspend (LGS) possibly preventing severe hypoglycaemia. In a prospective study, we investigated the effect of the LGS algorithm on the frequency of hypoglycemia in children and adolescents with type 1 diabetes under real-life conditions.

Materials and methods: Twenty-one patients with type 1 diabetes (age 10.8 ± 3.8 years, diabetes duration 5.9 ± 3.0 years, pump therapy 3.7 ± 1.7 years, A1C $7.8 \pm 1.1\%$) from 3 pediatric centers used the Paradigm VEO system (PR-VEO) during two subsequent time periods: SAP without LGS for two weeks and then SAP with LGS enabled for 6 weeks. The primary objective was to assess the frequency of hypoglycemic episodes when using the LGS feature with an insulin delivery shut-off of max 2 hours at a sensor glucose level below 70 mg/dL (3.9 mmol/L).

Results: A total of 1298 LGS alerts occurred, 853 were shorter than 5 minutes as patients reacted immediately and no interruption of insulin delivery took place. The frequency of LGS alerts was 2.56 ± 1.86 per patient/day (6am–10pm: 76%). Of all LGS episodes, 42% lasted less than 30 min while 24% took more than 120 min, respectively. LGS >120 min was more frequent in the night (84%). The AUC <70 mg/dL was decreased by using LGS (SAP vs. SAP+LGS: $0.76 \text{ mg/dL} \times \text{day}$ vs. $0.53 \text{ mg/dL} \times \text{day}$, $p=0.05$) as well as the time spent in hypoglycemia (average minutes/day: $101 \pm 68 \text{ min}$ vs. $58 \pm 33 \text{ min}$, $p=0.002$). Also, the number of hypoglycemic excursions was significantly reduced during SAP+LGS (excursions <70mg/day 1.27 ± 0.75 vs. 0.95 ± 0.49 , $p=0.01$, excursions $\leq 40 \text{ mg/dL}$: 0.28 ± 0.18 vs. $0.13 \pm 0.14 \text{ mg/dL/day}$, $p=0.005$) with no difference in the mean glucose level (145 ± 23 vs. $148 \pm 19 \text{ mg/dL}$). Regarding safety, no episodes of severe hyperglycemias or DKA were observed following LGS.

Conclusion: The present study provides evidence for reducing the risk for hypoglycemia with LGS without compromising the safety of CSII therapy.

Continuous subcutaneous insulin infusion (CSII) in type 2 diabetes: reductions in HbA_{1c} - mean glucose and variability

H. Anhalt¹, D. Rodbard², T. Bailey³, B.W. Bode⁴, R. Brunelle⁵, S. Edelman⁶, J.P. Frias¹, M.S. Kipnes⁷;

¹Animas Corporation, West Chester, ²Biomedical Informatics Consultants LLC, Clinical Research and Biostatistics, Potomac, ³AMCR Institute Inc, Escondido, ⁴Atlanta Diabetes Associates, Atlanta, ⁵B2S Consulting, Carmel, ⁶UCSD/VA TCOYD, San Diego, ⁷Cetero Research/Diabetes and Glandular Disease Clinic, San Antonio, USA.

Background and aims: Insulin infusion therapy has become a viable alternative for insulin deficient patients with type 2 diabetes. This study was designed to study clinical outcomes in poorly controlled patients with type 2 diabetes after initiating CSII.

Materials and methods: We evaluated the effect of CSII therapy in a 16 week open-label pilot study. 56 insulin pump naïve patients with type 2 diabetes previously treated with A) 2 oral agents alone B) oral agents plus basal insulin, or C) oral agents plus Multiple Daily Injection (MDI) insulin therapy were switched to CSII and monitored with Continuous Glucose Monitoring (CGM) at baseline, 1, 2, 3, 4, and 16 weeks.

Results: There were significant reductions in HbA_{1c}, mean glucose, SD of glucose within days, hyperglycemia, and percentiles of the glucose distributions. Reductions of HbA_{1c} and mean glucose were linearly related to baseline HbA_{1c} with similar relationships irrespective of previous treatment (Fig.). Most improvement occurred in the initial 4 weeks. Subjects with baseline A1C 9%-10% showed the most dramatic response. There was a small increase in risk of non-severe hypoglycemia.

Conclusion: Use of CSII rapidly improves glycemic control in patients with T2DM as documented by CGM; these effects are more significant after adjustment for baseline HbA_{1c} or mean glucose.

983

Improving the estimation of mealtime insulin dose in adults with type 1 diabetes: Normal Insulin Demand for Dose Adjustment (NIDDA study)

J.C. Brand-Miller¹, J. Bao¹, H.R. Gilbertson², R. Gray³, D. Munns³, G. Howard³, P. Petocz⁴, S. Colagiuri¹;

¹Boden Institute of Obesity, Nutrition & Exercise, the University of Sydney,

²Department of Nutrition and Food Service, Royal Children's Hospital,

Melbourne, ³Sydney Insulin Pump Clinic, ⁴Department of Statistics,

Macquarie University, Sydney, Australia.

Background and aims: Although carbohydrate counting is routine practice in type 1 diabetes, hyperglycaemic episodes are common. A food insulin index (FII) has been developed and validated for predicting the normal insulin demand generated by mixed meals in healthy adults. We sought to compare a novel algorithm based on the FII for estimating mealtime insulin dose with carbohydrate counting in adults with type 1 diabetes.

Materials and methods: Twenty eight patients using insulin-pump therapy consumed two different breakfast meals of equal energy, glycemic index, fibre and calculated insulin demand (both FII = 60) but ~2-fold difference in carbohydrate content, in random order on 3 consecutive mornings. On one occasion, carbohydrate counting algorithm was applied to meal A (75 g carbohydrate) for determining bolus insulin dose. On the other two occasions, carbohydrate counting (about half the insulin dose as meal A) and the FII algorithm (same dose as meal A) were applied to meal B (41 g carbohydrate). Real-time continuous glucose monitor (CGMS) was used to assess 3-h postprandial glycemia.

Results: Compared with carbohydrate counting, the FII algorithm significantly decreased glucose incremental area under the curve over 3h (-52%, $P < 0.01$), peak glucose excursion (-41%, $P = 0.001$) and improved the percentage of time within the normal BGL range (4–10 mmol/L) (+31%, $P < 0.001$). There was no significant difference in the occurrence of hypoglycemia.

Conclusion: The findings support the use of a FII algorithm based on insulin demand in healthy subjects to optimize glycemic control without increasing the risk of hypoglycemia in patients with type 1 diabetes.

The impact of the bolus and food calculator „Diabetics“ on decreasing postprandial glucose variability in children with type 1 diabetes treated with insulin pump: the results of RCT

M. Błazik, E. Pańkowska;

The Institute of Mother and Child, Warsaw, Poland.

Background and aims: Fluctuations of blood glucose levels expressed by the glucose variability is one of the main factors frustrating patients with diabetes in their daily self-management. Moreover, it is often masked by targeted level of HbA_{1c}. Bolus calculators as digital tools have to facilitate the process of insulin programming and are increasingly being introduced in treatment of patients with type 1 diabetes. The aim of the study was to determine whether the digital bolus calculator compared to traditional insulin programming has an impact on postprandial and diurnal glucose variability in children with type 1 diabetes treated with insulin pumps.

Material and methods: This 3-month, randomized, open-label study included 48 children aged 1–18 years. All patients were trained in food counting where carbohydrate unit (CU) and fat-protein unit (FPU) were taken into account in prandial insulin dosing by normal-wave or dual-wave boluses. Patients were subsequently randomly allocated to the experimental group (GA) which used digital bolus calculator ‘Diabetics’ for food and bolus calculation and to group B (GB) which used caloric tables. The parameters of glucose variability were estimated based on 8-point glucose profile (mg/dl).

Results: We observed significant differences between groups in all postprandial glucose variability parameters described by SD as well as the mean of all glucose values (Mean_T), SD of all glucose values (SD_T), SD of all glucose values within days (SD_W), SD between time points in 8-point glucose profile (SD_{h:mm}) and high blood glucose index (HBGI). We did not observe statistically significant difference in low blood glucose index (LBGI). All results are presented in table.

Conclusions: Introducing the ‘Diabetics’ software in prandial insulin programming stabilized daily glucose profile particularly in terms of postprandial values. The bolus calculator ‘Diabetics’ software is a safety tool for self-managing children with diabetes.

Glucose variability parameters (Mean±SD)

	SD 2h after breakfast	SD 2h after lunch	SD 2h after dinner	Mean _T	SD _T	SD _W	SD _{h:mm}	HBGI	LBGI

Unnoticed shift in the normal range of glycated HbA_{1c} with TOSOH high performance liquid chromatographyC. Kloos¹, T. Heller¹, K. Böer², W. Hunger-Battefeld¹, G. Wolf¹, U.A. Müller¹;¹Internal Medicine, Klinikum für Innere Medizin III, Jena, Germany, ²IKCL, Germany.

Background and aims: Changes of the normal range of the HbA_{1c} makes long term follow up of studies dealing with the treatment quality of diabetes difficult. Additionally, patient care with the treatment target normoglycemia, e.g. pregnant patients with diabetes, uses as its standard the lower limit of the normal range of the local method. Since 2004 the HPLC method from TOSOH has been used and as of April 2010 the TOSOH G8 analyser UIN 20305. For the follow-up of a 20 year long-term study the normal range of the HbA_{1c} was checked every 5 years. In summer 2010, after retesting the normal range in 150 healthy non-diabetic volunteers, the normal range was found to have shifted.

Materials and methods: To specify the time of the shift, the HbA_{1c} values of 30568 patients with and without diabetes at a university out-patient department for endocrinology and metabolic diseases in the period from 2004 to 2010 were analysed. Women with gestational diabetes were excluded. The data was retrieved from the electronic patient data file EMIL[®].

Results: Compared to 2004 the mean normal HbA_{1c} tested in healthy volunteers increased from 5.24±0.33 (2004, n=107) to 5.64±0.25 (2009, n=150), (p<0.001). The mean HbA_{1c} values of non-diabetic patients from 2004 to 2010 also increased in absolute figures 0.4% (p<0.001): 2004: 5.4±0.41 (n=383), 2005: 5.36±0.39 (n=710), p(2004/5) n.s., 2006: 5.43±0.42 (n=960), p(2005/6)<0.001, 2007: 5.61±0.44 (n=1026) p(2006/7)<0.001, 2008: 5.52±0.40 (n=1054), p(2007/8)<0.001, 2009: 5.65±0.38 (n=1079), p(2008/9)<0.001, 2010: 5.67±0.37 (n=635), p(2009/10) n.s. In the period from 2006 to 2007 a shift in the normal range occurred. However, the mean HbA_{1c} values of diabetic patients did not show a consistent increase: 2004: 7.48±1.11 (n=2336), 2005: 7.65±1.24 (n=3740), p(2004/5)<0.001, 2006: 7.67±1.27 (n=3939), p(2005/6) n.s., 2007: 7.81±1.24 (n=4382), p(2007/8)<0.001, 2008: 7.55±1.13 (n=4110), p(2008/9)<0.001, 2009: 7.67±1.10 (n=3839), 2010: 7.72±1.05 (n=2330), p(2009/10)=0.05. In these patients, a shift cannot be found.

Conclusion: In spite of keeping the same HbA_{1c} analysing method and the same HbA_{1c} device of the same manufacturer a shift in the normal range occurred. This was detected due to an investigator/user driven check of the normal range in April 2010. This shift causes considerable changes in the normalisation results when the normal mean of the HbA_{1c} method is used for adjustment in long-term studies. Patient care is also a concern. For instance is one treatment target of diabetic woman during pregnancy to achieve a HbA_{1c} in the lower limit of the normal range. Using our normal range, this was supposed to be below 5.2% but found to be below 5.6%. On the other hand, the range for near normal glycemic control of patients using the DCCT as a model (equal or below 1.4 times of the normal mean of the local method) is either below 7.3% taking 5.2% as normal mean, or 7.8% using 5.6% instead. Until now no statement referring to the shift could be obtained by the manufacturer. To date, comparability of HbA_{1c} measurements during long term follow-up remains a problem.

986

Development of new ways of measuring diabetes health in the Swedish National Diabetes Registry (NDR) taking a capability approachB. Palaszewski¹, F. Odegaard², S. Borg³, U. Lövgren¹, P. Roos⁴,S. Gudbjornsdottir¹;¹NDR, Gothenburg, Sweden, ²UWO, London, Canada, ³Swedish Institute for Health Econ (IHE), Lund, Sweden, ⁴RR Institute of Appl Econ, Lund, Sweden.

Background and aims: The aim of this project is to develop a method, as part of NDR, for measuring diabetes related health using biomedical and patient reported outcome measurements. In a health related capability approach (CA) the focus is on the individual well-being. We think of capability to perform functionings as a quality of life indicator, which can be improved from better understanding of how medical decisions affect living conditions.

Materials and methods: Using a newly developed questionnaire 4743 (801 type 1 and 3072 type 2) Swedish diabetes patients at 23 care centres were

asked to report their perceived diabetes related functioning for: health knowledge (self-care management, quality in communication with health care personnel); social life/working conditions (ability to overcome problems in daily life activities); confidence (anxiety for complications, access to health care). The response rate was 65%. The patients' clinical characteristics were representative for NDR and non responders did not differ in clinical characteristics from responders. All questions were measured on a 5 point Likert scale. Item Response Theory was used to translate ordinal data into scales. The resulting scales had good reliability, and scalability properties, as evaluated by Mokken Analysis were strong. Scores were calculated from the observed response pattern for each individual and each indicator. Scores were linked to indicators of the individuals' clinical characteristics. Indices reflecting various functioning a person potentially can achieve were obtained by using the 'ratio' between actual and potential functioning. In the construction of indices modern optimization methods, such as data envelopment analysis and Malmquist indices, were used. The constructed index was adjusted for differences in age, sex, onset age, and duration. An overall health index and two sub components (I Intermediate outcome of health services & II Health related daily life activities) were created.

Results: The results show variation among diabetes patients in all functioning indicators and the variation is much larger for sub index II compared to sub index I. Patients with Type 1 diabetes had more problems overcoming obstacles in social life and at work and more anxiety than those with type 2 diabetes (mean sub index II was 0.79 vs 0.84). Patients with type 2 diabetes on insulin had more problems in social life and at work and more anxiety compared to patients on diet or oral treatment (mean sub index II was 0.81 vs. 0.90). Results also show a non linear relationship between medical health variables and a person's potential functioning, i.e. non-proportional effects are observed for changes in medical variables. Furthermore, for some patients increased knowledge on how to live with diabetes has a greater positive impact on quality of life than improvements in some biomedical variables.

Conclusion: CA is very useful since it incorporates not only medical data on patients' health but also information on individuals functionings and capabilities. The method can also be used on an individual level, e.g. to evaluate the meeting between doctor/nurse and patient, as well as to identify patients with suboptimal health. Future work could result in an overall model for assessment of the provision of diabetes health care services, that can handle the complexity of provided services.

A systematic review of the impact of culturally-competent diabetes care interventions for improving diabetes-related outcomes in ethnic minority groups

P. Zeh^{1,2}, J.A. Sturt¹, H.K. Sandhu¹, A.M. Cannaby²;

¹Warwick Medical School, University of Warwick, Coventry, ²Research & Development, UHCW NHS Trust, Coventry, UK.

Background and aims: The provision of culturally-appropriate interventions to ethnic minority groups (EMGs) can confer important benefits, to the person with diabetes, their families and also bring about cost savings in every nation's healthcare system. However, recent systematic reviews on EMGs with diabetes have found limited evidence involving culturally-competent interventions. Because of this paucity and uncertainty regarding effective culturally-competent interventions, a systematic review with narrative analysis was undertaken, aimed to examine the effectiveness of culturally-competent interventions and innovations tailored to the needs of EMGs with diabetes globally.

Materials and methods: Four databases (Medline (NHS Evidence), CINAHL, Cochrane, DARE) and reference lists of retrieved papers were searched from inception to April 2010, including two NHS specialist libraries for diabetes, and ethnicity and health. In addition, we searched the Warwick Medical School Research Publications from 2006 to 2010. Paper selection and appraisal were conducted independently by two reviewers. The criteria for inclusion in the analysis were all effectiveness studies of any specified diabetes health-related intervention to any EMG within a majority population with diabetes. Data were collected on all reported outcome measures.

Results: Ten out of 271 studies were included. The heterogeneity of the studies required narrative analysis. Participants were recruited from 3 settings (primary care, hospital or community) and varied greatly such as South Asians, Russians, Hispanics, Turkish, etc. Study designs were varied and involved delivery by diverse range of health workers, e.g. certified diabetes edu-

cators, registered dieticians, podiatrist, multilingual link workers, bilingual health advocates, etc. Various outcomes were reported which included 7 self reported outcomes (e.g. satisfaction with diabetes education programmes), 9 assessed by staff (eye checks) and 4 objective validation (HbA1C). No study formally set out to systematically assess the cost effectiveness of their culturally-competent interventions or the quality of life. Although there were methodological limitations within the studies, findings suggest that interventions tailored to EMGs by integrating the element of culture into that intervention, (cultural and religious beliefs including linguistic and literacy skills), produced a positive effect. This was consistent in most of the ten studies.

Conclusion: We identified benefits in using culturally-competent interventions with EMGs with diabetes. Due to the mixed methodologies and outcome measures in the review, the data did not allow for convincing comparisons across countries, EMGs, or the type of interventions. However, further culturally-competent interventions are required and should include the cost-effectiveness evaluation which can easily influence diabetes service commissioners to decide on its implementation. Furthermore, there is need for culturally-competent structured education programmes which should include community leaders/companions of specific EMGs.

Age related quality of care; are younger, socially deprived patients disadvantaged?

B. Young^{1,2}, A. Uddin², J. Barrett², J. Henderson²;

¹Salford Royal Hospital, Salford, ²NHS Information Centre, Leeds, UK.

Background and aims: The 'epidemic' of diabetes is thought to be predominantly a problem of later life. Faced with the volume of demand services may struggle to deliver optimal care and there is the possibility that age related gaps in service quality may emerge. The English National Diabetes Audit (NDA) includes the majority of people with diagnosed diabetes. It assesses key annual processes of diabetes care, treatment target achievement rates and disease outcomes. Its comprehensiveness and scale enables general issues of deficient service delivery to be identified reliably. The 2009-10 data was examined for evidence of age related differences in care and/or outcomes.

Materials and methods: The NDA uses Primary Care, Specialist Care and Hospital Admission data collected electronically with an approved dataset. It is linked securely, confidentially and centrally in the NHS Information Centre. This annual national audit is now in its seventh year.

Results: In 2009-10 the English National Diabetes Audit included 1.9 million people, 83% of those with diagnosed diabetes in England. Between ages 10 years and 80 years Type 1 diabetes prevalence varies little (0.34-0.55 per cent). By contrast, Type 2 diabetes prevalence rises from 0.05% for ages 16-24 years and peaks at 14.44% for ages 70-84 years. In consequence those age <55yr are in the minority (24%). Also among those age <55yr Type2 diabetes is more than twice as common in the most deprived (3.0%) quintile of socioeconomic deprivation as in the least deprived quintile (1.3%); whereas above age 55yr there is no deprivation effect. Younger people less frequently received the nine core processes of care (all care processes were completed in only 20% age 16-24 years, 38% age 25-54 years but 55% age 55-84 years). Achieving the HbA1c ≤7.5% (58mmol/mol) treatment target was similarly less likely in younger people: thus for Type1 diabetes age <25yr it was <15% but in those age ≥55yr it was >30%; and for Type2 diabetes age <55yr it was <50% but in those age >70yr it was 70%. Appreciable numbers of complications start appearing in the 25-55 year age group after 10-20 years of diagnosed diabetes: 91% of DKA; 62% of End Stage Kidney Disease (ESKD) in Type1 and 15% of ESKD in Type2; 15% of Major amputations; and 12% of Myocardial Infarctions occur under age 55yr. All complications are 1.5-2.2 times more common in the more severe social deprivation quintiles.

Conclusion: The NDA confirms that the diabetes 'epidemic' is heavily weighted to older people. However, measures of care quality in younger people with both Type1 and Type2 diabetes are poorer than in older people. Furthermore social deprivation is associated with younger onset Type2 diabetes and complications risk. There should be a focus of effort on improving the effectiveness of services for younger people with diabetes who seem to be disadvantaged by comparison with their older counterparts.

Quality of care from the perspective of patients with type 2 diabetes: a comparison between integrated and usual diabetes careG. Nijpels¹, A.A.W. van der Heijden¹, L.D. René¹, M.C. de Bruijne¹, C.A. Baan^{1,2}, S.D.M. Bot¹, T.L. Feenstra^{2,3}, G.A. Donker⁴, J.M. Dekker¹;¹The EMGO Institute for Health and Care Research, VU University Medical Center, Amsterdam, ²National Institute for Public Health and the Environment (RIVM), Bilthoven, ³University Medical Center Groningen, ⁴Netherlands Institute for Health Services (NIVEL), Utrecht, Netherlands.

Background and aims: Integrated care using a patient-centred approach, can improve the interaction between the patient and health care professional, resulting in high-quality, satisfying consultations. We aimed to compare the perceived quality and continuity of diabetes care between patients receiving integrated diabetes care and usual care.

Materials and methods: 307 type 2 diabetes patients receiving integrated diabetes care by the Diabetes Care System and 463 type 2 diabetes patients receiving usual care participated in our study in the Netherlands. The Diabetes Care System coordinates the diabetes care between primary and secondary care. Patients have a central role in their care and are stimulated to make their own choices regarding treatment options and lifestyle behaviour. Self-management is stimulated and individual care plans are discussed with the patient. General practitioners receive feedback about their performance. Patients in the usual care group received care according to the current guidelines for type 2 diabetes by general practitioners only. A validated questionnaire, the QUality Of care Through the patients' Eyes questionnaire (QUOTE) for diabetes, was used to obtain information on patients' opinion about the quality and continuity of the diabetes care. Quality scores were calculated by combining the importance of aspects of care rated by the patient, with patients' experience with these aspects. We specified aspects of care that needed improvement and differentiated between patients' opinion on diabetes care by the general practitioner, the diabetes nurse and the dietician.

Results: In both groups, the discussion of aims and trajectory of treatment with the patient received good quality scores. With respect to the quality of care, most differences between the two diabetes care groups were seen in the care by the dietician, which was in favour of the Diabetes Care System. Regarding the continuity of care, many aspects were rated more favourable by patients treated by the Diabetes Care System compared to patients receiving usual diabetes care (Table).

Conclusion: Patients receiving integrated diabetes care experienced overall better quality of diabetes care and better continuity of care than patients receiving usual diabetes care.

Continuity of care scored by patients receiving integrated care and patients receiving usual care					
	Importance	Negative experience (%)		Quality score	
		integrated care	usual care	integrated care	usual care
It is important that... / It is my experience that...					
I received intensive support after diagnosis of diabetes	7.8 (2.1)	17.8	17.3	1.38	1.35
it is possible to consult a specialist in ophthalmology within 2 months	7.4 (2.2)	20.6	14.1*	1.58	1.01
I receive good education about self-control feet	7.2 (5.9)	5.9	20.5*	0.43	1.47
I receive a screening of the foot each year	7.4 (7.7)	2.3	19.7*	0.17	1.44
I receive a screening of the eyes each year	7.7 (1.9)	8.4	14.6*	0.65	1.12
I receive a screening of kidney function each year	7.6 (2.1)	31.4	41.5*	2.45	3.10
my blood pressure is assessed during each check-up	7.6 (1.9)	1.3	6.1*	0.10	0.46

Negative experience: proportion of patients that answered 'no' or 'not really' regarding the aspect of care.

* Indicates a significant difference ($p < 0.05$) in experience between the two groups.

A quality score between 0 and 1 indicates good quality. A quality score higher than 1 indicates low quality.

Glycaemic and risk factors control in type 1 diabetes: results from DIACAM 1 StudyJ. Sastre¹, P. Pines², J. Moreno³, B. Blanco⁴, S. Herranz⁵, R. Chamorro⁶, D. Calderon⁷, A. Marco¹, J. Lopez¹, DIACAM 1 study group;¹Endocrinology, Complejo Hospitalario de Toledo, ²Endocrinology, C H de Albacete, ³Endocrinology, CH Mancha Centro, Alcazar de San Juan, ⁴Endocrinology, H. Nra Señora del Prado, Talavera de la Reina, ⁵Endocrinology, H. U. Guadalajara ⁶Endocrinology, H. G. Ciudad Real, ⁷Endocrinology, H. Virgen de la Luz, Cuenca, Spain.

Background and aims: DIACAM 1 study was designed to investigate the clinical characteristics of a representative group of type 1 diabetic (T1D) population in Castilla La Mancha, a region in central Spain. The aim of this report is to evaluate metabolic control and to describe the prevalence of cardiovascular risk factors and the degree of control achieved.

Materials and Methods: This is an observational, cross-sectional, prospective and multicentre study of 1465 patients who received assistance in endocrinology clinics during 2010 as hospital outpatients. This cohort represents about 33% of the adult T1D patients in Castilla La Mancha. All reported patients were aged > 16 years at the time of the study and duration of diabetes was > 5 years. Diabetic patients underwent clinical and laboratory evaluation. Type of treatment was registered (insulin regimen, antihypertensive drugs and lipid lowering drugs). We consider intensive insulin regimen (IIR) when patients deliver insulin via multiple daily injections (MDI) or continuous subcutaneous insulin infusion (CSII) with SMBG ≥ 3 day and self adjusting. Measurement of HbA1c was standardized to DCCT in all the laboratories. A multivariate logistic regression analysis was used to assess variables independently associated with good glycemic control ($\text{HbA1c} \leq 7\%$). P value less than 0,05 was considered statistically significant. Statistical analysis was done by SPSS 15.0

Results: Among 1465 patients, there were 48,5% women, mean age $39,4 \pm 13,5$ years and mean diabetes duration $19,4 \pm 10,6$ years. Mean HbA1c was: $7,8 \pm 1,2\%$. 26% of the patients reached $\text{HbA1c} \leq 7\%$, 62% had $\text{HbA1c} \leq 8\%$ and only 15% of the group had $\text{HbA1c} > 9\%$. 45% was treated with IIR (35% MDI and 9% CSII). In multivariate regression analysis: IIR (OR 2,56; 95% CI 1,97-3,34, $p < 0,01$), higher educational level (OR1,33; 95% CI 1,06-1,74 $p < 0,05$) and absence of smoking (OR 1,66 ; 95% CI 1,22-2,26 $p < 0,01$) were independently associated with $\text{HbA1c} \leq 7\%$. The prevalence of cardiovascular risk factors was (% CI95%): BMI > 30 15% (13,1-16,9), central obesity 26% (23,3-28,7), dyslipidemia 35%(32,5-37,5), hypertension 23% (20,8-25,2) and smoking 26% (23,7-28,3). 38% of the group was treated with lipid lowering drugs and 28% were receiving antihypertensive drugs. Lipids and blood pressure levels and degree of control are shown in table 1.

Conclusions: In this cohort of T1D patients glycemic control is still unsatisfactory, implementation of healthy attitudes (smoking cessation) and intensifying insulin treatment will improve glycemic control. Prevalence of cardiovascular risk factors is high in T1D although treatment goals are satisfactory.

Table 1	mean \pm sd	Targets (ADA 2010)	% (95%CI)
LDL-c (mg/dl)	102 ± 26	≤ 100	49 (46,3-51,7)
HDL-c (mg/dl)	58 ± 15	≥ 50	69 (66,5-71,5)
Triglycerides (mg/dl)	89 ± 106	≤ 150	91 (89,5-92,5)
Systolic BP (mmHg)	126 ± 16	≤ 130	71 (68,6-73,4)
Diastolic BP (mmHg)	73 ± 10	≤ 80	81 (78,9-83,1)

Evaluation of the benefits of a regional pre-pregnancy care program in women with type 1 and type 2 diabetes: a prospective study

E. Mustafa, B. Kirwan, S. Khalil, L. Carmody, T. Gallacher, Y. Mitchell, M. Todd, M. Durkan, F. Dunne; Department of Medicine, College of Medicine, Nursing and Health Sciences, Galway, Ireland.

Background and aims: Diabetes is the commonest medical problem in pregnancy with increased risks for both mother and infant. To decrease perinatal morbidity and mortality to that of the background population and improve maternal morbidity women need to attend pre pregnancy care (PPC) to optimize their glycaemic control, use folic acid, review medications and screen

for diabetic complications. As part of our ATLANTIC DIP program we are undertaking a single arm prospective study to compare pregnancy outcomes in women who attend (attendees) PPC to those who decline an invitation to attend (Non-attendees).

Materials and methods: Through ATLANTIC DIP and DIAMOND databases, hospital and primary care registers, 541 women of child bearing age with Type 1, Type 2 Diabetes or IFG/IGT following GDM were identified. Patients were contacted by invitation letter and followed by a phone call to confirm their interest in attending one of 4 PPC clinics established in the region. Consent was obtained at their first visit. The PPC intervention centers around pregnancy specific education, dietary advice, glycaemic targets, review of medications, review of complications, rubella status and commencement of folic acid. Data on maternal and infant outcomes of pregnancy and glycaemic control are collected real time on DIAMOND.

Results: To date 131 women (24.2%) have consented and attended for PPC 71 Type 1 and 60 Type 2+IGT/IFG). Of these 131 women there are 67 confirmed pregnancies. All received folic acid (100%) and mean HbA1c was 6.6% (5.2–8.5) prior to conception with >80% attendees with HbA1c 7%) and uptake of folic acid in only 43% (1). 15 invited but declined PPC patients had 15 confirmed pregnancies with a mean pre pregnancy HbA1c of 8.1% (5.2–11.7) and folic acid uptake of 27%. 52 pregnancies have now delivered. The miscarriage rate was 7.0% and admission to neonatal unit (NNU) 19% in attendees compared to 13% and 40% respectively in non-attendees. The background population rates are 15% and 11% respectively. The figures for miscarriage and NNU admission in women receiving PPC is significantly better than our previous reported rates of 22% and 48% respectively (1). The caesarean section rate was lower in attendees (48%) compared to non-attendees (60%). There were no differences in stillbirth rates between groups. No congenital anomalies reported.

Conclusion: The increased uptake of folic acid and improvement in glycated haemoglobin levels are encouraging. This is translated into a decrease in miscarriage and an increase in take home baby rates. In addition caesarean sections and admissions to NNU care are less in attendees resulting in financial savings. The low rate of uptake is of concern and requires further investigation through focus groups.

The impact of the UKPDS Risk Engine on cardiovascular risk management in patients with type 2 diabetes mellitus in general practice

M. Van den Donk, A.E. Wind, K.J. Gorter, G.E.H. Rutten;
Julius Center for Health Sciences and General Practice, University Medical Center Utrecht, Netherlands.

Background and aims: It is not clear whether prediction rules, like the UKPDS risk engine, have added value to cardiovascular risk management of type 2 diabetes mellitus (T2DM) patients in general practice. In this study, we want to investigate this by answering the following research questions: Which patient characteristics are associated with under- or overestimation by the general practitioner (GP) of the cardiovascular risk of T2DM patients? What is the impact of the UKPDS risk engine on prescription of medication by the GP and on cardiovascular risk factors?

Materials and methods: A 12-months observational study in 993 patients on the list of 117 GPs. Risk factors for cardiovascular disease were collected at baseline and after 12 months. GPs had to estimate the cardiovascular disease risk themselves and by using the UKPDS risk engine, and subsequently had to state if they had adjusted the patient's medication. Generalised Estimating Equation (GEE) modelling was used to identify independent predictors of under- and overestimating patient's cardiovascular risk, taking into account clustering of patients within GPs. The impact of the UKPDS risk engine was assessed by measuring the differences in medication adjustments and changes in metabolic variables between the over- and underestimated group during 12 months.

Results: The mean difference between the cardiovascular disease risk estimated by the GP and calculated with the UKPDS engine was -0.36 (95% CI -1.24;0.52), ranging from 52% underestimation to 72% overestimation. Age (year), male gender, HbA1c (%), total cholesterol (mmol/l), HDL-cholesterol (mmol/l) and current smoking were associated with underestimation of cardiovascular risk by the GP (respective ORs (95% CI): 1.14 (1.11;1.18), 7.45 (4.61;12.04), 1.54 (1.18;2.00), 2.16 (1.70;2.74), 0.05 (0.02;0.11), 2.19 (1.28;3.75)). HbA1c was associated with overestimation of cardiovascular risk by the GP (OR 1.33, 95% CI 1.07;1.65). Patients with an underestimated cardiovascular risk received significantly more medication adjustments com-

pared with overestimated and accurately estimated patients. More improvements in cardiovascular risk factors after 12 months were seen in the underestimated group.

Conclusion: Age, gender, HbA1c, total cholesterol, HDL-cholesterol and smoking were associated with underestimation, and HbA1c was associated with overestimation of cardiovascular risk by the GP. The UKPDS risk engine is of added value for cardiovascular risk management in T2DM patients in general practice and can improve medication prescription and cardiovascular risk factors in this high-risk target group.

Pursuing perfection in the diabetes review clinic

P. Grant;

Diabetes & Endocrinology, Kings College Hospital, London, UK.

Background and aims: Timely, thorough and holistic evaluation of the patient with diabetes, screening for complications and strategies to prevent future problems is the mainstays of the diabetes review clinic. However, these types of clinics have varying formats and content depending on their organisation, efficiency and locale. We wished to prospectively assess how successful we were being at asking about and accurately recording data relating to two important aspects of ongoing diabetes; neuropathy symptoms such as erectile dysfunction (in men) and pregnancy plans (in women of child bearing age). Both are stressed as significant in the latest NICE guidelines for diabetes care.

Materials and methods: We collected anonymised information about the content of the diabetes review consultation through two main processes. Firstly, a post-consultation neuropathy screening questionnaire which was given to patients in the manner of an exit poll to collect information about whether the patient has been asked about various neuropathy symptoms including erectile dysfunction (the clinician being blinded to this occurrence). Secondly, data from the diabetes database DIABETA 3 was mined to reveal whether young females had their pregnancy intentions discussed (there being a forced choice checkbox within the computer programme) and subsequent pre-conception counselling arranged for those who were actively planning to become pregnant.

Results: With regards to erectile dysfunction we discovered that only 21% of men with diabetes attending the annual review clinic were asked about this particular symptom and overall that diabetologists fared poorly in enquiring about all the different potential signs and symptoms of neuropathy. With regards to pregnancy intentions and arranging follow up pre-conception planning, only 12% of female patients (of child bearing age, 16–45 yrs) were asked about this.

Conclusion: It would appear as though the diabetes review clinic is sub-optimal in its ability to explore and screen for signs and symptoms of neuropathy, such as ED in men, as well as crucially finding out about pregnancy plans in young females. The former is significant because of its impact on quality of life and the second is potentially devastating because of the consequences of poorly controlled diabetes in the ante-natal period. Given that 'prevention is better than cure' it would seem germane to look at better ways of information gathering in the context of the diabetes review clinic. To this end we have designed a pre-consultation neuropathy screening tool which is in the process of being validated and a more rigorous approach to enquiring about pregnancy plans in women of child bearing age with diabetes. New modalities such as 'Care Planning' may well be the way forward.

Hypoglycaemia in a hospital setting: a survey on nursing practices from a tertiary care hospital in India with a case for the role of diabetes nurse educator

N.M. Thomas, A. James, S. Jha, S. Waghdhare, M. Sahu;
Endocrinology, Max Super Speciality Hospital, New Delhi, India.

Background and aims: Hypoglycemia is a known complication of insulin therapy. Patient related factors as causes of hypoglycemia have been widely studied with relative paucity of studies on nursing practices contributing to hypoglycemia and its management. We conducted a survey at a single tertiary care hospital on the ongoing practices for hypoglycemia management our corrective measures based on the observations and a repeat survey.

Materials and methods: A survey was done on hospital records from Dec 2008 to March 2009 for cases of hypoglycemia (BG < 70 mg/dL) on insulin

therapy. Reaction time was noted, defined as time between the first documentation of hypoglycemia and any oral or parenteral intervention. A questionnaire survey was done on nursing staff to check on understanding of hypoglycemia management. Based on initial assessment, corrective intervention was done. A repeat audit was done in the year 2010 on case records over four months duration for a pilot comparison.

Results: There was lack of uniformity of hypoglycemia management across wards with long reaction time (6–12 minutes) for managing 41 instances of hypoglycemia. Possible sources of overdosing included misinterpretation of prescription notes, and surprisingly a lack of appropriate understanding of U40 and U100 insulin's specific syringes. Corrective measures were put in place by introducing hypoglycemia protocol, glucose insulin chart, hypoglycemia tool kit for all wards, availability of single strength insulin (U100) and regular education to nursing staff on hypoglycemia management. In the second audit, there were 25 episodes of hypoglycemia with reaction time of 2–4 minutes with no discrepancy between physicians' prescription and nursing administrations.

Conclusion: Although not a controlled study to assess outcome measures of intervention, the pilot study revealed key observations of lack of uniform practices of hypoglycemia management, prolonged reaction time, and some of the old errors of insulin IU and syringe mismatch. All these factors are readily avoidable by continuous education to nursing staff providing a case for the role of diabetes educator nurse at all hospitals in India and abroad.

PS 087 Health care delivery 2

995

Impact of medication treatment on mortality and readmission in patients with hyperglycaemia prior to and during hospitalisation

R. Juneja¹, G. Kongable², S. Thompson³, T. Germanson²;

¹Endocrinology, Indiana University School of Medicine, Indianapolis,

²The Epsilon Group, Charlottesville, ³sanofi aventis, Bridgewater, USA.

Background and aims: Little is known about the impact of medical management of diabetes before hospitalization on in-hospital mortality and readmissions.

Materials and methods: Using a hospital database linked to outpatient data with 73,977 admissions between July 1, 2003 and December 31, 2009, we identified 18,078 patients with a clinical encounter 12 months before and after an "index" admission (IA). To gain understanding of impact of pre-admission medical treatment on hospitalization outcomes, we evaluated diabetes (DM) status and use of antidiabetic medication pre-admission (PA) and during IA and further examined the association of mortality with anti-diabetes, antihypertensive and antilipidemia medication treatment.

Results: At IA mean age was 50 ± 16 years and 52% were female. At IA 25% had pre-existing DM (Group A), 7% were newly diagnosed (Group B), 27% were not DM but with hyperglycemia (any BG > 140 mg/dl) (Group C) and 41% were not DM with no hyperglycemia (Group D). During IA, nearly 60% had hyperglycemia or DM diagnosis and 349/18,078 (1.9%) died. Group C had the highest mortality during IA, 216/349 (62%), a 2.8 fold increase compared to Group A and B DM patients ($p < .0001$). Patients receiving insulin or oral hyperglycemic medication (OHM) either PA or during IA experienced lower mortality than those not receiving insulin or OHM, ($p < .0001$, $p < .007$). Less than half of Group A patients were receiving antihypertensive and antilipidemia medication treatments PA. In Group A and B patients, patients who were not taking these therapies PA had a 2- and 3-fold higher mortality risk than those patients who were. Mortality in patients in Group C and D was not affected by these medications.

Conclusion: This study showed that mortality risk was lower in patients receiving Insulin and or OHM either PA or during IA across all groups, suggesting that hyperglycemia treatment offers a mortality benefit. The presence of drugs commonly associated with CV protection in the outpatient setting might also offer some protection for hospitalized patients. Further analysis of mortality risk adjusting for comorbidity at IA will be required to confirm this relationship.

996

Impact of providing people with type 2 diabetes with their actual risk for five diabetes complications: a pilot study

T.C. Skinner¹, M. Barrett², C. Greenfield³;

¹Rural Clinical School, Flinders University, Mount Gambier, ²School Nursing and Midwifery, Curtin University of Technology, Perth, ³Rural Clinical School, University of Western Australia, Geraldton, Australia.

Background and aims: Many individuals feel hopeless and helpless to manage their diabetes. These individuals vastly overestimate their risk of developing complications, and underestimate their ability to reduce their risks. Previous research suggests that providing people with their actual risk of complications, reduced their distress and increased their engagement in risk reduction information. Therefore, this feasibility study sought to determine whether providing people with poorly controlled type 2 diabetes with their actual risk for the complications of diabetes (heart attack, stroke, blindness, amputation, kidney disease), would lead to improved control and reduced psychological distress.

Materials and methods: Individuals with poor control of their diabetes (HbA1c > 8.0; plus one of BP > 140/80, smoker, Total Cholesterol > 4.0) were recruited from GP practices in three rural communities in Western Australia. Baseline assessment of lipids, HbA1c, BP, depression (CESD) and diabetes distress (PAID) were completed, and individuals were randomized to receive personalized complication specific risk information alone, provided by the Mellibase risk engine, or risk information with a 3 monthly structure goal setting and telephone support program. At 9 months after baseline assessment, individuals completed a second assessment of all outcome measures.

Results: 54 individuals were randomized across the two groups. There were no significant differences between control and intervention groups at baseline or completion of the study, for HbA1c, lipids, BP, depression or diabetes distress. However, both groups evidenced significant reductions in HbA1c (Baseline HbA1c= 8.8; SD=0.9; Post HbA1c=8.2; Sd =1.4; $p<.001$), and for those who had cholesterol above target at baseline (Baseline Total Chol=5.3 SD=1.0; Post = 4.5; SD=1.2; $p<.01$). Participants also reported less distress (Baseline PAID= 16.6 SD=14.4; Post PAID=13.8;SD 11.8; $p<.05$), but there was no effect on depression.

Conclusion: Providing people diabetes with personalised complication specific information about their risk of microvascular and macrovascular complication may facilitate more pro-active management of diabetes and reduced diabetes related emotional distress.

Does a PDA improve knowledge about treatment choices for patients with type 2 diabetes mellitus when making decisions about starting insulin? Quantitative analysis from the PANDAs study

B. Colwell¹, N. Mathers¹, A. Bradley¹, C.-J. Ng²;

¹Academic Unit of Primary Medical Care, University of Sheffield, UK,

²Department of Primary Care Medicine, University of Malaya, Kuala Lumpur, Malaysia.

Background and aims: Type 2 diabetes (T2DM) is a common illness, affecting about 2.8 million people in England in 2010. Despite lifestyle changes and glucose lowering drugs, a significant number of these people continue to have poorly controlled blood sugar due to disease progression. As poor glucose control leads to an increased risk of developing complications (eg stroke, coronary heart disease, renal problems), doctors will eventually recommend insulin therapy. However, uncertainty about the treatment choices may lead to patients delaying their decision about starting insulin. Using quantitative data from the PANDAs study we will explore how knowledgeable patients are about their treatment choices.

Materials and methods: PANDAs (Patients ANd Decision Aids) is a cluster randomised controlled trial (RCT) that was conducted across South Yorkshire. Its aim was to establish whether the use of a patient decision aid improves the decision quality and health outcomes of patients with T2DM who are considering insulin therapy. The decision aid provides the patients with key facts about their T2DM as well as clarifying their own values on management of their diabetes, in order to help them make a decision about their treatment. Patients recruited into the both arms of the study were asked to complete a questionnaire before and after their consultation with their usual Health Care Professional, part of which explored their knowledge about treatment choices whilst patients in the intervention arm also completed a decision aid prior to their consultation.

Results: A total of 175 patients were recruited into the study; 95 intervention and 80 control. The mean age was 65 years (\pm 10 SD). 96 participants were male, and the mean duration since diagnosis of diabetes was 8 years (\pm 4 SD). When asked if they knew which treatment choice has the greatest chance of lowering their blood sugar, 23/80 control and 49/95 intervention chose the correct answer ($p=.002$ chi square). When asked about number of 'hypo's they might experience in a year, if taking insulin, 4/76 control and 77/95 intervention chose the correct answer, ($p=.000$ chi square), and when asked how much weight they might gain in a year, if taking insulin, 4/75 control and 67/95 intervention chose the correct answer ($p=.000$ chi square). When asked about their risk of getting complications in 5 years if they were to go onto insulin, 4/80 control and 25/95 intervention chose the correct answer, ($p=.000$ chi square). There was no significant difference between the two groups when asked about which treatment would lower their complications.

Conclusion: Patients in the intervention group are more knowledgeable about their treatment choices after using the decision aid compared to the patients in the control arm. Decision Aids, such as the PANDAs decision aid can help to improve the knowledge of patients about their illness and treatment options which can help them make an informed decision about their future treatment.

DiabetesE: an innovative and effective alternative to peer review for assessing and benchmarking the quality of diabetes service provision

H. Seymour, B. Wright, K. Moore;

Innove, Manchester, UK.

Background and aims: DiabetesE is an online self assessment tool which measures and benchmarks the quality of diabetes service provision and drives continuous quality improvement. Users can update their answers whenever they wish and data is analysed instantly. DiabetesE was launched in 2003, in England, to support the implementation of the Diabetes National Service Framework and is one of a suite of complementary tools which operate under the auspices of the National Diabetes Information Service. The aim of DiabetesE is to provide a methodology for undertaking a comprehensive assessment of the quality of diabetes services in England to inform local commissioning and national priority setting and to encourage service improvement.

Materials and methods: Two new questionnaires were developed, one focusing on diabetes services commissioning and another on specialist diabetes service provision. A review of national diabetes related policy and clinical literature was undertaken and an expert reference group of service users, clinicians and managers advised on the draft questions. These were grouped into 3 commissioning and 12 specialist diabetes provider modules. An interactive process was used to refine and agree the final set of questions and for each question a supporting rationale, based on current evidence, was built into DiabetesE via electronic links. The expert reference group ranked the modules and questions so that a scoring and weighting system could be devised and applied, enabling the automatic generation of scores and of prioritised recommendations for encouraging service improvement. Users can compare their results locally, regionally and nationally and view National Diabetes Audit outcome data. The questionnaires were piloted in summer 2010 and launched in November 2011.

Results: By 31st January 2011, 107 commissioning organisations and 124 specialist diabetes providers had assessed their services. Modules are scored as a percentage (100% = best possible score). The Diabetes in Pregnancy module had the highest mean score (82%). Although the Children and Young People with Diabetes module was the next highest scoring (72%), 4% of services scored under 25%. The majority of services scored over 50% in all the modules, with the exception of Inpatient Management of Active Diabetic Foot Disease, which had the lowest mean score (45%) and for which only 37% of specialist diabetes providers scored over 50%, with 17% scoring under 25%. Kidney Screening and Management was the second lowest scoring module (59%), with 34% of providers scoring under 50% and 5% scoring below 25%. In one of the commissioning and four of the specialist diabetes provider modules, a few services scored 100%, notably for Staff Development, where 8% of specialist diabetes providers achieved this score.

Conclusion: DiabetesE data captured at the end of January 2011 provides a detailed snapshot of the quality of diabetes care in England. The variation between module scores indicates that some aspects of diabetes service provision are better than others, but significant work remains to bring all services up to national standards. Whereas peer reviews capture information about service provision at a specific time, DiabetesE data is updated instantly and on an ongoing basis. Progress in improving all aspects of diabetes care can therefore be quickly and easily monitored through implementation of the DiabetesE recommendations and use of the integral benchmarking functionality, making DiabetesE an effective alternative to peer review.

999

Optimal type 2 diabetes management including benchmarking and standard treatment: Portuguese data for the OPTIMISE study

J.S. Duarte¹, R. Cernadas², F. Ribeiro³;

¹Endocrinology Department, Centro Hospitalar de Lisboa Ocidental,

²Agrupamento de Centros de Saúde Espinho/Gaia, Espinho, ³Astrazeneca, Lisboa, Portugal.

Background and aims: Current medical practice is not always successful in achieving therapeutic goals for glycemia, blood pressure and cholesterol. The benchmarking technique can improve diabetes treatment by giving feedback to physicians on the achievement of pre-set targets according to current guidelines. The OPTIMISE study, carried out in 6 European countries, aims at demonstrating that the use of benchmarking improves quality of care for patients with type 2 diabetes. This abstract describes Portuguese results.

Materials and methods: Participating investigators were randomly assigned to a benchmarking or to a control group in a ratio of 3:1. All investigators received feedback on each patient's risk factors. The benchmark group also received an anonymous comparison with their colleagues. The primary end-point was the percentage of patients achieving pre-set targets according to European guidelines (2007) for HbA_{1c} (7%), low-density lipoprotein cholesterol (LDL-C (<100 mg/dl) and Systolic Blood Pressure (SBP <130 mmHg), after 12 months.

Results: A total of 15 investigators recruited 185 patients, 134 for the benchmark group and 51 for the control group. Patients' baseline characteristics were not significantly different. Patients had a median age of 61.4 years (minimum 37.1 and maximum 92.3) and 50.8% were women. At the time of study inclusion, a mean 11.7 years had elapsed since diagnosed with diabetes. The most commonly used diabetes medication was biguanides (78.4%), with biguanide-sulfonamide being the most frequent combination (22.8%). Statins were the most commonly used class of lipid lowering medication (89.9%) and sartans (61.6%) and diuretics (57.2%) were the most frequent hypertensive therapies. In general, the number of patients who reached each clinical target increased between baseline and 12 months. The target for SBP was achieved by 23.2% (benchmarking 23.2%; control 23.3%) of patients at baseline and by 25.9% (benchmarking 22.1%; control 33.3%) after 12 months. At baseline 27.7% of patients were on target for HbA_{1c} (benchmarking 28.1%; control 26.9%) and after 12 months this increased to 32.2% (benchmarking 30.9%; control 34.8%). The number of patients reaching LDL-C target levels increased from 41.6% (benchmarking 40.3%; control 45.5%) at baseline to 45.8% (benchmarking 46.7%; control 43.6%) after 12 months. All three targets were achieved by 3.4% of patients (benchmarking 3.79%; control 2.38%) after 4 months and by 3.6% after 8 months (benchmarking 3.91%; control 2.44%). After 4 and 8 months the amount of patients achieving all three targets was higher for the benchmarking group. At the 12 month point this decreased to 1.5% (benchmarking 1.04%; control 2.56%).

Conclusion: Despite the small differences between groups, the amount of patients achieving each of the evaluated targets increased between baseline and 12 months. Between the benchmarking and the control groups, more patients in the benchmarking group achieved the three targets after 4 and 8 months of follow-up. However the opposite was shown after the 12 month period. The achievement of therapeutic goals for type 2 diabetes in Portugal is still suboptimal and may be influenced by numerous factors. In order to improve quality of care for Portuguese diabetes patients, the implementation of interventions such as benchmarking is still necessary.

Clinical Trial Registration Number: NCT00681850

Perioperative diabetes care: gap between recommended care and current practice

I. Hommel¹, P.J. van Gurp², C.J. Tack², H.W. Wollersheim¹, M.E. Hulscher¹;

¹IQ Healthcare, ²Internal Medicine, UMC St. Radboud, Nijmegen, Netherlands.

Background and aims: Optimal perioperative diabetes care reduces mortality, infection rates and length of hospital stay. Daily practice however, shows that optimal perioperative diabetes care is very often not achieved. To identify key problems in the delivery of optimal perioperative diabetes care, we first defined optimal perioperative diabetes care by developing quality indicators, and subsequently measured current quality of care.

Materials and methods: To define optimal perioperative diabetes care, a systematic RAND-modified Delphi method was used to derive a set of key recommendations from international literature and guidelines on perioperative diabetes care. The resulting set of key recommendations was systematically transformed into 17 indicators on professional performance, 9 indicators on organizational structure, and 4 indicators on patient outcome. A focus group interview in diabetic patients on their experiences with previously received perioperative diabetes care, yielded 12 complementary indicators on patient-oriented quality. To measure current quality of care, indicator performance was assessed in 400 diabetic surgical patients from six Dutch hospitals. Diabetic patients were included if they had abdominal surgery during general anesthesia, heart surgery or large joint orthopedic surgery with a minimum operative time of one hour in the period march 2009-march 2010. Professional performance was assessed by medical record search. Organizational structure was assessed by questionnaire. Selected patients received a questionnaire on patient-oriented quality.

Results: Regarding professional performance, medical records revealed information on preoperative glycaemic control in only 55% (24-87%) of patients. Preoperative information on macrovascular complications was retrieved in 92% (82-96%) of patients, whereas preoperative information on microvascular complications was recorded in only 28% (6-78%) of patients. Recordings of intraoperative blood glucose values could be retrieved in merely 27% (2-54%) of patients. Regarding organizational quality, protocols concerning perioperative diabetes care were present in all six hospitals. A multidisciplinary team in which all professionals involved in perioperative diabetes care were represented was absent in all six hospitals. Regarding patient outcome, 44% (41-52%) of postoperatively measured blood glucose values on the surgery ward were between 6-10 mmol/l. Regarding patient-oriented quality, only 41% (35-47%) of patients received information on diabetes medication regime in the perioperative period.

Conclusion: This study identified multiple opportunities for improvement of perioperative diabetes care. To improve perioperative diabetes care, we performed in-depth interviews with professionals involved in the perioperative diabetes care process. These revealed a lack of knowledge, lack of agreement on responsibilities of the various involved care takers, lack of insight into own performance and the perception that perioperative diabetes care has low priority. To improve perioperative diabetes care, a multifaceted strategy to address these key problems including education, multiprofessional establishment of a perioperative diabetes care protocol, feedback on performance, and patient oriented interventions is needed.

Approaches to insulin intensification in the A_{1c}chieve observational study

A.V. Zilov¹, I.M. Hajjaji², G. Gonzalez-Galvez³, P. Soewondo⁴, C. Jianwen⁵, M.I. Hasan⁶;

¹Dept. of Endocrinology, First Moscow State Medical University, Moscow, Russian Federation, ²National Centre for Diabetes and Endocrinology, Tripoli, Libyan Arab Jamahiriya, ³Instituto Jalisciense de Investigacion en Diabetes y Obesidad, SC, Guadalajara, Mexico, ⁴Department of Internal Medicine, Division of Endocrinology and Metabolism, University of Indonesia, Faculty of Medicine, Jakarta, Indonesia, ⁵Medical & Science Department, Novo Nordisk Pharmaceuticals, Beijing, China, ⁶Miracles (Diabetic Institute Pakistan), Lahore, Pakistan.

Background and aims: Current evidence substantiates various strategies for intensifying an insulin regimen as type 2 diabetes progresses. Patient characteristics, HbA_{1c}, previous therapy and regional differences may strongly influence physicians when intensifying an insulin regimen.

Materials and methods: Data from A_{1c}chieve - a large, global, observational study conducted across seven regions (China; South Asia; East Asia; North Africa; Middle East/Gulf; Latin American and Russia) - were used to explore the relationship between therapy before the study start and choice of subsequent insulin regimen intensification under routine clinical conditions throughout.

Results: Three main groups (total n=4237) were identified: basal±oral glucose-lowering drugs (OGLDs) switched to mealtime+basal insulin (MB) [n=470]; premix±OGLDs switched to MB [n=979]; and basal±OGLDs switched to premix±OGLDs [n=2788]. Demographic characteristics were similar between the basal-to-MB, premix-to-MB and basal-to-premix groups: mean age 54.2 (SD 11.9), 52.7 (14.0) and 57.4 (11.2) yr; duration of diabetes was 12.4 (7.4), 12.8 (7.9) and 12.6 (8.0) yr; and HbA_{1c} 9.7 (1.8), 9.5 (1.7) and 9.6 (1.8)%, none of which predicted regimen choice. Likewise, morning fasting plasma glucose (FPG) was similar before intensification across all groups (range 10.3-10.8 mmol/l), as was postprandial glucose (PPG) (post-breakfast) 14.3-15.1 mmol/l. Overall hypoglycaemia was most frequent in the premix-to-MB group compared with the basal-to-MB and basal-to-premix groups (28.4, 24.5 and 14.1%), as was major hypoglycaemia (7.4, 4.8 and 2.1%). Insulin dose increment was highest in the basal-to-MB group compared with the basal-to-premix and premix-to-MB groups (31.6 to 51.4 vs 29.9 to 36.9 and 53.6 to 57.8 U/day). There were strong regional differences in choice of insulin regimen, with difference in choice of starting regimen affecting subsequent approaches to intensification (Table). Generally, people treated with basal insulin were more likely to be intensified to a premix insulin regimen than to a mealtime+basal regimen. In China, premixed insulin is more commonly used than basal or prandial, the reverse being true in Russia and Latin America.

Conclusion: Mean HbA_{1c} at baseline, irrespective of insulin regimen choice, predicted that treatment intensification was overdue. Regional dif-

ferences rather than patient characteristics or disease duration are predictors both of regimen when beginning insulin and subsequent pathway of intensification.

Regional distribution of people starting insulin and those intensifying within 6 months

Baseline characteristics of the First Basal Insulin Evaluation in Asia (FINE Asia) study population

K. Suastika¹, S.-T. Tsai², J. Wang³, K. Tan Eng Kiat⁴, E. Wang⁵, J. Lin⁶, L. Ji⁷, FINE Asia Study Group;

¹Udayana University / Sanglah Hospital, Bali, Indonesia, ²Taipei Veterans General Hospital, Taipei, Taiwan, ³Jinling Hospital, Nanjing, Jiangsu, China, ⁴Mount Elizabeth Medical Centre, Singapore, Singapore, ⁵sanofi-aventis, Bridgewater, NJ, USA, ⁶Novosys Health, Flemington, USA, ⁷Peking University People's Hospital, Beijing, China.

Background and aims: First Basal Insulin Evaluation in Asia (FINE Asia), a multinational, 6-month, prospective observational study, assessed the use of basal insulin in insulin-naïve Asian patients (aged ≥ 20 years) with type 2 diabetes mellitus, uncontrolled ($A1C \geq 8\%$) on oral antihyperglycemic drugs (OADs). Here we compare baseline characteristics across 11 Asian countries.

Materials and methods: Basal insulin was initiated with or without concomitant OADs; all treatment choices were at the physician's discretion. A total of 2921 patients were enrolled at baseline; 2679 patients with both baseline and 6-month HbA_{1c} values were included in the analysis.

Results: Demographic characteristics and insulin regimen at baseline are shown in the table. Most patients initiated insulin therapy with insulin glargine. Across the countries/region, mean duration of diabetes ranged from 6.3 to 11.5 years and mean baseline HbA_{1c} ranged from 9.4% to 10.5%. The prevalence of microvascular disease ranged from 14% to 39%, coronary artery disease from 9% to 21%, and dyslipidemia from 49% to 84%.

Conclusion: The results indicate that treatment intensification and the initiation of insulin are delayed in patients in these countries, irrespective of international, regional, and local treatment guidelines, and that management of other metabolic risk factors is delayed as well.

Initiation of basal insulin in patients with type 2 diabetes: national differences in glycaemic control after 6 months in a subanalysis of the FINE Asia database

J. Wang¹, L. Ji², K. Suastika³, K. Tan Eng Kiat⁴, E. Wang⁵, J. Lin⁶, S.-T. Tsai⁷; ¹Jinling Hospital, Nanjing, Jiangsu, China, ²Peking University People's Hospital, Beijing, China, ³Udayana University / Sanglah Hospital, Bali, Indonesia, ⁴Mount Elizabeth Medical Centre, Singapore, ⁵sanofi-aventis, Bridgewater, USA, ⁶Novosys Health, Flemington, USA, ⁷Taipei Veterans General Hospital, Taipei, Taiwan.

Background and aims: FINE Asia is a prospective, observational registry undertaken to evaluate basal insulin initiation in patients in Asia with type 2 diabetes mellitus who were inadequately controlled by oral antihyperglycemic agents. This subanalysis compared findings by individual participating countries.

Materials and methods: The primary efficacy end point was change in HbA_{1c} from baseline to Month 6 after basal insulin initiation. Secondary end points included change in fasting blood glucose (FBG) from baseline to Month 6, HbA_{1c} and FBG responses rates, change in insulin dose, and hypoglycemic events.

Results: The study enrolled 2921 patients from 11 Asian countries (countries with small patient numbers are pooled as Southeast Asia); 2679 patients with both baseline and 6-month HbA_{1c} values were included in the analysis. Overall, HbA_{1c} decreased from $9.8 \pm 1.6\%$ to $7.7 \pm 1.4\%$ at Month 6 after starting basal insulin (NPH insulin, insulin glargine, or insulin detemir); 33.7% of patients reached $HbA_{1c} < 7\%$. Glycemic control at Month 6 varied greatly by country (Table), with a low of 10.6% and a high of 75.4% of patients in Taiwan and China, respectively, reaching the HbA_{1c} target. The increase in insulin dose ranged from 0.5 U in Pakistan to 6.0 U in Thailand. Rates of hypoglycemia also varied from 2.2% of patients in India to 15.9% of patients in China experiencing at least 1 event.

Conclusion: National data from the FINE Asia study show widely varying degrees of glycemic control in patients depending on their country, with China having the highest percentage of patients achieving $HbA_{1c} < 7\%$ but also having the highest rate of hypoglycemia.

Country	n	Baseline HbA _{1c} % (SD)	Δ HbA _{1c} % (SD)	Patients With HbA _{1c} < 7, %	Patients Reaching FBG < 110 mg/dl, % (SD)	Δ Total Daily Insulin Dose, U (SD)	Patients With Hypoglycemia, %
China	491	9.4 (1.6)	-2.6 (1.5)	75.4	54.8	1.2 (4.6)	15.9

Self-rated health predicts overall mortality in patients with type 2 diabetes

P. Wennberg¹, L. Jerdén^{1,2}, U. Nöthlings^{3,4}, O. Rolandsson¹;

¹Public Health and Clinical Medicine, Umeå University, Sweden, ²Center for Clinical Research Dalarna, Falun, Sweden, ³Department of Epidemiology, German Institute for Human Nutrition (DIfE), Potsdam, Germany, ⁴Section for Epidemiology, Institute for Experimental Medicine, Christian-Albrechts-University Kiel, Germany.

Background and aims: Self-rated health scores have shown to be predictors of vascular events and major complications in diabetes patients. We aimed to investigate whether low self-rated health is associated with increased mortality in patients with type 2 diabetes (T2D).

Materials and methods: Self-rated health was assessed with four answering alternatives in self-administered questionnaires in 3257 patients (mean ± SD age was 55.8 ± 7.6 years and 41.6% women) with confirmed diagnosis of T2D. Enrolment took place between 1992 and 2000 in four centers (Bilthoven, Heidelberg, Potsdam, Umeå) in a sub-cohort nested in the European Prospective Investigation into Cancer and Nutrition. Causes and dates of deaths were ascertained using record linkages with boards of health, death indexes and cancer registries or by follow-up mailings and subsequent inquiries to municipal registries, regional health departments, physicians, or hospitals. We used Cox proportional hazards modeling to estimate hazard ratios (HRs) with 95% confidence intervals (95% CIs) associated with self-rated health controlling for age, sex, BMI, physical inactivity, hypertension, hyperlipidemia treatment, smoking, previous myocardial infarction and cancer diagnosis.

Results: During follow-up (mean follow-up ± SD was 8.6 ± 2.3 years), 344 deaths (241 men/103 women) occurred including 40.4% cardiovascular deaths. In a multivariate model, patients rating their health as “moderate” or “poor” were associated with increased mortality (HR 1.45, 95% CI 1.16–1.81, Figure 1) compared to patients rating their health as “excellent” or “good”. As a comparison, the HR for smoking was 1.58 (95% CI 1.23–2.03) in the same model. We found no indication of heterogeneity between centers (see Figure 1).

Conclusion: Low self-rated health is associated with increased mortality in patients with T2D after controlling for established risk factors. Whether this association can be extended to a more specified mortality outcome such as cardiovascular deaths, needs to be investigated in larger studies.

Figure 1. Forest plot showing adjusted hazard ratios and 95% CIs for the centres included in the study investigating the association between low self-rated health and mortality in patients with type 2 diabetes.

How accurate are blood glucose meters used for patient self testing

M.J. O’Kane, M. McCloskey, C. Diver-Hall;

Clinical Translational Research and Innovation Centre, Londonderry, UK.

Background and aims: There is increasing concern being expressed about the accuracy of glucose meters used both in hospitals and for self-testing. A number of endogenous and exogenous substances can influence the accuracy of results and as such several bodies (ISO, IFCC, FDA) are looking at revised performance criteria for glucose meter performance. The purpose of this study was to challenge the analytical performance of commonly used SMBG meters and to compare the clinical performance of the best and worst performing meters.

Materials and methods: Seven SBGM meters (NovaMax plus, Glucofix Mio plus, Glucomen Lx plus, AccuCheck Aviva, Ascencia Breeze 2, Optium Xceed, and OneTouch Ultra 2) were tested. The meters were challenged with differing hematocrit levels and differing levels of non-glucose sugars (maltose, galactose, xylose) and at five different glucose concentrations (1.1–3.3, 5.5–8.3, 11.1–16.7, 18.1–22.2 and 23.6–27.8 mmol/L). Each individual sample was tested 6 times with each meter. Results were compared to the YSI reference method and the mean bias deviation calculated for each meter. The imprecision of each meter was determined at three different levels and this was used in conjunction with the bias deviation to calculate mean total error (%bias + 1.65 CV(%)). A method correlation was performed using a spiked sample panel. The meters showing the best and poorest total errors were selected for a study performed on capillary samples collected from self-testing diabetic outpatients.

Results: An example of the mean total error rates for all glucose meters at a glucose range of 11.1–16.7 mmol/L is presented in the Table. The Nova Max plus, Glucofix mio and Glucomen Lx were unaffected by the interferences assessed and demonstrated low and acceptable total error rates. The other meters were affected to varying levels by the interfering substances. The Nova Max plus, Glucofix mio and Glucomen Lx and One Touch Ultra were selected for diabetic patient testing. Initial data shows that the varying levels of haematocrit seen in diabetic outpatients, also affect the accuracy of One Touch Ultra.

Conclusion: The accuracy of SMBG meters can be affected by haematocrit as well as non-glucose sugars. The results pattern seen in the analytical assessment for haematocrit also occurs with real patient samples. In accurate meters increase the risk of mis-management of diabetes and new performance criteria for SMBG meters need to take this into account.

Meter	Method correlation	Hct (22%)	HCT (62%)	Maltose (5.6 mmol/L)	Galactose (5.6 mmol/L)	Xylose (5.6 mmol/L)
NovaMax Plus	8.5%	9.3%	5.8%	6.8%	6.7%	7.8%
Glucofix mio Plus	7.8%	3.8%	5.8%	11.5%	9.1%	6.4%
Glucomen Lx Plus	7.2%	7.1%	4.1%	8.3%	10.4%	4.7%
AccuCheck Aviva	9.5%	20.2%	13.4%	20.2%	68.0%	15.4%
Ascencia Breeze 2	9.5%	31.6%	32.7%	19.8%	13.0%	9.3%
Optium Xceed	15.5%	28.9%	46.8%	14.7%	11.5%	13.6%
One Touch Ultra	16.6%	42.9%	43.0%	17.0%	21.9%	16.3%

First clinical assessment of a blood glucose predictor and therapy advisor in type 1 diabetes: The DIAdvisor-1 Trial

E.M. Renard^{1,2}, A. Farret¹, J. Place³, S. Costa⁴, A. Maran⁴, A. Avogaro⁴, M. Mindlova⁵, E. Vavrova⁵, F. Saudek⁵, DIAdvisor Consortium;

¹Endocrinology, Diabetes, Nutrition, CHU Montpellier, Montpellier Cedex 5, France, ²Cic 1001, INSERM, Montpellier, France, ³UMR CNRS FRE 3400, University of Montpellier I, Montpellier, France, ⁴Metabolic Medicine, University of Padova, Italy, ⁵Centrum Diabetologie, IKEM, Prague, Czech Republic.

Background and aims: Timely adjustments of insulin doses in type 1 diabetes (T1D) according to variable insulin needs remain a heavy burden for patients in everyday life. In spite of specific education, the common failure in achieving this task results in frequent out-of-target blood glucose control. The

DIAdvisor device has been designed in view of predicting blood glucose at a close time horizon and delivering advice on correction measures in order to maintain blood glucose in a near-normal target range in T1D patients using a basal-bolus insulin regimen by multiple daily insulin injections or insulin pumps. Inputs include patient information on carbohydrate intakes, insulin dose administration and continuous glucose monitoring (CGM) data. In a pilot study, we investigated the ability of collecting inputs by the system, the accuracy of blood glucose prediction at a 20-min horizon and the coherence of treatment advices.

Materials and methods: Sixteen T1D patients volunteered to assess DIAdvisor device in a Clinical Research Centre setting in three successive steps. Blocks of 4 patients were included successively, allowing for system refinement, until success criteria were reached at each step. The primary endpoints and success criteria were: in step A, a percentage of data collection from CGM for 48 hours > 80%; in step B, an accuracy of blood glucose prediction at a 20-min horizon assessed by using Clarke error grid analysis of paired predicted glucose values and YSI glucose measurements for 48 hours with > 80% of paired points in A+B zones and <5% in E zone; in step C, a coherence of advices given by the system on glucose and insulin corrections compared to clinician's advices for 48 hours > 80%. The DIAdvisor device includes an Ultra Mobile (UM) PC with a patient interface and a USB connection to a CGM DexCom Seven-Plus receiver. Algorithms for glucose prediction and treatment advice are uploaded on the UMPC. Predictions and advices were blinded to the patient but wirelessly transmitted to a nearby clinician monitoring station.

Results: In step A, the success criteria were reached after the inclusion of 8 patients with 85.7% of CGM data collected for 48 hours. In step B, the accuracy of glucose prediction at 20 min was validated after the inclusion of 8 patients as shown by 90.9–100% of paired points in A+B zones and 0% in E zone in the second block of 4 patients. In step C, the coherence of system advices reached 96.5% in a series of 11 consecutive patients with 85.7% full coherence in terms of suggested insulin or glucose correction amounts.

Conclusion: This pilot study shows that the DIAdvisor system is able to provide successful prediction of blood glucose at a 20-min horizon and coherent advices for treatment correction in T1D patients in a standardized hospital environment. Further trials will assess the DIAdvisor system in less controlled conditions.

Use of an automated bolus calculator reduces fear of hypoglycaemia and improves confidence in dosage accuracy in type 1 diabetes mellitus patients treated with multiple daily insulin injections

K. Barnard¹, C. Parkin², M. Ashraf²

¹University of Southampton, Chilworth, UK, ²CGParkin Communications, Inc., Las Vegas, USA, ³Roche Diagnostics Limited, Burgess Hill, UK.

Background and aims: Intensive management of glycemia can significantly reduce the development/progression of diabetic complications. Achieving optimal glucose control often requires intensive insulin therapy. Many patients, however, are reluctant to intensify (or even follow) their prescribed insulin regimen because of fear of hypoglycemia; patients with type 1 diabetes (T1DM) experience an average of two episodes of symptomatic hypoglycemia each week and at least one episode of severe, disabling hypoglycemia, annually. We hypothesized that utilization of an automated bolus calculator (ABC) might reduce fear of hypoglycemia and encourage patients to achieve improved glycaemic control.

Methods and materials: We sent a 45-item questionnaire to 1,412 T1DM patients treated with multiple daily insulin injection therapy (MDI) at 270 hospitals and clinics throughout the United Kingdom and Republic of Ireland. The questionnaire was designed to assess their attitudes and behaviors regarding insulin therapy after use of an ABC (Accu-Chek[®] Expert system, Roche, Diagnostics, Indianapolis, USA). The hand-held device allows patients to test their blood glucose and obtain meal and correction bolus recommendations based upon their current blood glucose value, planned carbohydrate intake, and patient-specific therapy parameters stored in the device.

Results: 588 T1DM patients responded to the survey. Respondents were predominantly female (57.5%), age 0 to 70 years (31.0% age less than 18, 56.8% age 18–50, 12.2% age 51–70), with diabetes duration ranging from 0–2 years (18.5%) to greater than 15 years (39.6%). Patients had 4–12 weeks experience using the ABC prior to receiving the questionnaire. More than 95% of respondents indicated that they used multiple daily insulin injection (MDI) therapy with a long-acting analog. 76.7% of 562 respondents indicated

that they use the ABC to calculate insulin boluses for meals/snacks always (53.6%) or quite often (23.1%); 232 (41.5%) of 559 respondents stated that they used the ABC to calculate correction boluses always (15.0%) or quite often (26.5%). 478 (89.3%) of 535 responders indicated that the ABC made bolus calculation easy or very easy compared with manual calculation: 44.9% vs. 26.0% and 44.5% vs. 8.4%, respectively. 292 (52.0%) of 561 respondents indicated that their fear of hypoglycemia was improved (39.0%) or significantly improved (13.0%); 442 (78.8%) indicated that their confidence in the insulin dose calculation either improved (50.8%) or significantly improved (28.0%).

Conclusion: Although most patients indicated consistent use of mealtime boluses based on carbohydrate counting prior to using the ABC, the majority of patients surveyed felt that using the ABC was easier than manual bolus calculation, improved their confidence in the accuracy of their bolus dosage, and reduced their fear of hypoglycemia. Randomized trials are needed to confirm these perceptions, and to determine whether ABC use improves clinical outcomes.

Clinical evaluation of a new technology for blood glucose monitoring: accuracy at hypoglycaemic glucose levels

J. Ellison¹, M. Malecha², K. Koria², H. Cameron², K. MacLeod², S. Bellary³, P. Raja¹

¹LifeScan, Inc., Milpitas, USA, ²LifeScan Scotland Ltd., Inverness, UK, ³Heart of England NHS Trust, Birmingham, UK.

Background and aims: Monitoring for hypoglycemia is an essential component of glucose testing at home; however, most of the data found in published accuracy evaluations fall in the normoglycemic or hyperglycemic ranges. We studied the accuracy of OneTouch[®] Verio[™] Pro test strips, a new blood glucose monitoring technology, at hypoglycemic glucose levels (<70 mg/dL) using data collected in four clinical studies conducted at two clinical sites.

Materials and methods: In each clinical study, testing was performed by clinic staff using fingertip blood samples from subjects with diabetes. The study population included 414 subjects, and testing was conducted using nine different lots of test strips. With each subject, duplicate tests with each test-strip lot were performed with the monitoring system using blood from a single fingertip lancing. The blood glucose concentrations of samples were targeted to achieve the distribution specified in standard testing guidelines (ISO 15197:2003 standard). Plasma glucose reference values were obtained before and after testing with the blood monitoring system by using the YSI 2300 STAT Plus[™] Glucose Analyzer system. The number and percentage of results within ± 15 mg/dL and ± 10 mg/dL were calculated at blood glucose levels <70 mg/dL and <60 mg/dL.

Results: In total, 366 blood glucose results were evaluated at concentrations <70 mg/dL (range 32–69 mg/dL). In this glucose range, 100% (366 of 366) of OneTouch VerioPro results were within ± 15 mg/dL and 99.5% (364 of 366) were within ± 10 mg/dL of YSI reference values. At glucose concentrations of <60 mg/dL, 100% (174 of 174) of OneTouch VerioPro results were within ± 15 mg/dL and 100% (174 of 174) were within ± 10 mg/dL of YSI reference values.

Conclusions: Reliable detection of hypoglycemia requires accurate blood glucose monitoring. In this preliminary evaluation, the data from four clinical studies suggest that the new monitoring technology utilized in the OneTouch VerioPro test strips is capable of providing highly accurate results at hypoglycemic blood glucose levels. Further studies are needed to confirm the long-term performance of the system.

1009

Evaluation of a non-invasive method to determine blood glucose levels based on near-infrared spectroscopy coupled to a neural network system

A. Ciudin, C. Hernández, R. Simó; Endocrinology and Nutrition, Diabetes and Metabolism Research Unit (Vall d'Hebron Research Institute), Barcelona, Spain.

Background and aims: Tight control of blood glucose levels is essential for preventing or arresting diabetic complications. In those patients under insulin treatment, self-monitoring of blood glucose levels will be crucial for achieving the therapeutic objectives. The currently used devices use capillary blood obtained by pricking the fingers tips. Obviously, this procedure is annoying and for this reason a lot of diabetic patients reduce the number of auto-analyses to a minimum. Therefore, it is reasonable to postulate that

a non-invasive method that took the same time as the classic glucometers would improve the quality of life of diabetic patients and permit them to optimize their glycemic control, thus reducing both acute and late diabetic complications. The aim of this study was to assess whether a noninvasive method based on near-infrared spectroscopy to determine blood glucose levels had the same reliability as the meters currently used for blood glucose self-analysis.

Materials and methods: We prospectively evaluated 253 consecutive diabetic patients by comparing the estimated value of blood glucose using the new digital device with the venous glucose level determined simultaneously by the gold standard method (glucose-oxidase). The digital device is similar to a pulse oximeter, emits near-infrared (NIR) light and is coupled with a neural network system. In order to infer the blood glucose value, the prediction model included the following variables: age, sex, body mass index (BMI), saturation of oxygen (SaO₂), heart rate and blood pressure (the three last variables were determined at the time of blood collection). Data were analyzed by logistic regression analysis and the results were represented in the Clarke Error Grid.

Results: As can be seen in the figure, 95.5% of the blood glucose values estimated by the noninvasive method were located in areas with high accuracy of the Clarke's error grid (A and B zones). Only in patients with morbid obesity and severe hypertension we detected errors that are not acceptable for the current clinical practice (C, D, and E zones of the Clarke Error Grid).

Conclusion: The proposed noninvasive test is reliable for measuring blood glucose levels and could replace current blood glucose meters. The main consequences for the health care systems would be the following: 1) Improvement of the quality of life of diabetic patients. 2) Increase of self-monitoring, thus resulting in better metabolic control. 3) Reduction in the economic burden related to diabetes due to the dramatic decrease in glucose test strips consumption.

1010

Progressing towards a truly non-invasive glucose monitor for home use
Y. Mayzel¹, A. Gal¹, I. Harman-Boehm², E. Naidis¹, L. Trieman¹;

¹Integrity Applications, Ltd., Ashkelon, ²Internal Medicine and the Diabetes Unit, Soroka University Medical Center, Beer-Sheva, Israel.

Background and aims: Non-Invasive (NI) tracking of physiological phenomena correlated with Blood Glucose (BG), using a single method encountered obstacles of non-specificity, since factors, other than glucose, influence tissue parameters as well and cause inaccuracies in the reading. In order to minimize the impact of those disturbances, a methodology combining multi-technology and multi-sensors was previously introduced. Each technology measures different tissue parameters that are affected by the same change in glucose, but is confined by the impact of interfering factors, due to lack of specificity. Therefore, a simultaneous evaluation of the above mentioned

physiological changes through measurement of different sets of tissue perturbations, induced by changes in glucose concentration, is expected to increase the validity of the end result. GlucoTrack[®] glucose monitor combines 3 NI technologies: Ultrasonic, Electromagnetic and Thermal. These technologies, together with the adjunct sensors, are located at the tip of a Personal Ear Clip (PEC), which is clipped externally (non-invasively) to the earlobe for the duration of less than a minute, to conduct a spot measurement and is removed afterwards. The weighted average reading reflects the BG value with smaller impact of interferences, leading to more accurate real-time, spot readings.

Materials and methods: The device performances were evaluated in Clinical trials, initially launched in a clinic and sequentially followed by home trials. In the Clinic group, 91 subjects were evaluated (1772 data pairs): 12 T1DM and 79 T2DM, 41 F and 50 M, age 51.0 ± 30.0 years and BMI of 30.0 ± 10.0 Kg/m². The trial was performed in two different days per each individual. The time intervals between calibration and measurement days were 11.5 ± 10.5 days. In the Clinic group, GlucoTrack and the invasive reference device related actions (calibration and measurements) were performed in the clinic by a proficient medical staff. For evaluation of the upgraded device performances and ease of use in home environment, 12 subjects were tested (800 data pairs): 2 T1DM and 10 T2DM, 4 F and 8 M, age 47 ± 22 years with BMI of 31.7 ± 5.0 Kg/m². The calibration was individually performed by the medical team. Post-calibration measurement procedure was performed by the subjects themselves in their home/work environment for 2-37 days, with a median of 16 days.

Results: Clarke Error Grid (CEG) analysis for the in-clinic group shows 97% of the points in the clinically accepted zones A+B, of which 60% in zone A. MARD_{mean} is 22.4 % and MARD_{median} is 16.3 %. CEG analysis for the Home group shows 94% of the points in the clinically accepted A and B zones, of which 54% in zone A. MARD_{mean} is 25.3 % and MARD_{median} is 18.3%.

Conclusion: The presented methodology shows promising results in both, Clinic and Home groups. The initial home trials show no significant degradation relative to the results obtained in the clinic, including relatively long time after calibration. However, when comparing between home and clinic groups' results, small variation is observed. The small deviations observed might be attributed to user related issues, e.g. disobeying the rules of correct invasive measurement. The key benefits of GlucoTrack include long intervals between re-calibrations and the ability to perform frequent spot measurements with acceptable accuracy, present high likelihood for a solution to improve BG monitoring adherence.

Clinical Trial Registration Number: 4823

1011

Evaluation of performances and efficacy of GlucoTrack[®], a truly non-invasive glucose monitor for home and home-alike use

A. Gal¹, Y. Mayzel¹, I. Harman-Boehm², E. Naidis¹, L. Trieman¹;

¹Integrity Applications, Ltd., Ashkelon, ²Internal Medicine and the Diabetes Unit, Soroka University Medical Center, Beer-Sheva, Israel.

Background and aims: Inconvenience, expenses, pain and complexity involved in conventional SMBG, lead to under-utilization. Availability of an accurate, painless, easy to operate and non-expansive device will encourage more frequent testing. Previous publications indicate that GlucoTrack[®], a Non-Invasive (NI) glucose monitor, is able to measure glucose by using a combination of three technologies: Ultrasonic, Electromagnetic and Thermal. GlucoTrack comprises a Main Unit and 3 different sensor pairs, assembled at the tip of a Personal Ear Clip (PEC). The measured tissue parameters reflect physiological changes occurring in the tissue, correlated with blood glucose variation. Interpretation of these parameters into a glucose value is done based on individual calibration process. The calibration minimizes the affect of the individual quasi-stable factors such as tissue thickness and structure, sets a baseline for physiological change detection and allows finding optimal glucose behavior model parameters to be suited for each user. The multi-technologies combination is essential to reduce inaccuracies in the glucose readings, since factors, other than glucose, influence the measured tissue parameters as well. Thus, the weighted average reading of the three technologies reflects blood glucose value with smaller impact of interferences, leading to more accurate, real-time spot glucose readings.

Materials and methods: GlucoTrack performance was evaluated in Home use environment for 12 subjects: 2 T1DM and 10 T2DM, age 47 ± 22 years with BMI of 31.7 ± 5.0 Kg/m². The calibration was individually performed by a medical team, using invasive blood glucose references. This easy procedure takes about 1.5-2 hours and is valid for at least over a month. Post-calibration spot glucose measurements were performed by clipping the PEC externally

to the earlobe. Each subject performed the measurement procedure by him/herself at home/work environment for 2–37 days, with a median of 16 days. Data records were collected according to participants' own routine of glucose monitoring (timing and number of readings per day), but no less than 5 measurements per day. During each measurement, simultaneous pairs of GlucoTrack and invasive reference readings were collected. GlucoTrack readings were compared with the participants' own (invasive) glucose monitoring devices, which served as the reference for calibration, as well as for comparison of measurements. In addition, users' feedbacks regarding operation were analyzed.

Results: Clarke Error Grid analysis of 800 data points shows 95% of the readings within the clinically accepted A and B zones, of which 54% in zone A. $MARD_{mean}$ is 25.3% and $MARD_{median}$ is 18.3%. 97% of the users found the device to be comfortable for use and 87% of the users declared they'll use the device more frequently than the invasive one. Home trials are still currently ongoing.

Conclusion: Initial readings under real home conditions suggest that GlucoTrack gives good results. The users' feedbacks indicate that the device is user friendly and easy to operate under normal home environment and conditions, as well as willingness to use it more frequently. Such a device can be beneficial for diabetics in improving monitoring adherence and allow diabetics a frequent and painless way to monitor and track their BG, leading to tighter glucose control.

Evaluating glucose area under the curve (AUC) measurements by minimally invasive interstitial fluid extraction technology: comparison to AUC measured by continuous glucose monitor

S. Ugi¹, Y. Nishio¹, K. Morino¹, S. Yoshimoto¹, C. Kusunoki¹, T. Sato², S. Okada², K. Hagino², Y. Kikkawa², J. Kojima², T. Watanabe², H. Nakajima³, A. Kashiwagi¹, H. Maegawa¹

¹Department of Medicine, Shiga University of Medical Science, Otsu,

²Sysmex Corporation, Kobe, Japan, ³Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka, Japan.

Background and aims: Controlling postprandial glycemic excursions is important. However, monitoring blood glucose 2 hours after a meal by self-monitoring of blood glucose is not always appropriate since the glycemic excursions depend on several factors such as dietary content and patient's condition. We have newly developed the monitoring system for glucose area under the curve (AUC) using minimally invasive interstitial fluid extraction technology (MIET), which enables us to perceive the complete glucose excursion as the area measured. We have confirmed that glucose AUC measured using MIET correlated well with that calculated with plasma glucose during OGTTs in diabetic patients. In this study, we compared glucose AUCs measured using MIET with those measured by continuous glucose monitoring (CGM).

Materials and methods: Thirteen diabetic patients underwent CGM (CGMS-Gold, Medtronic) and were simultaneously measured glucose AUC using MIET. MIET consists of the following two steps. First, a plastic micro-needle array is applied to the skin of the forearm as the pretreatment to enhance transdermal interstitial fluid glucose (IG) extraction. It does not cause any pain or bleeding, since the length of each microneedle is only 0.3 mm. Second, a hydrogel patch is placed on the pretreated area to accumulate IG for a predefined period. Hydrogel patches were attached at two sites pretreated with microneedle arrays, and replaced by new patches every 2 hours for 6–8 hours. Patients had breakfast and lunch during this period. After the extraction of IG, accumulated glucose levels in the hydrogel patches were measured to predict IG-AUC. Extracted sodium ion levels were simultaneously measured for the calibration.

Results: Predicted AUC using MIET correlated well with that using CGM ($r = 0.84$) over a wide AUC range (170–548 mg·h/dl). Correlation level was independent of the IG level, IG variation rate, IG variation range, or extraction period. The mean CV of the two simultaneous measurements at different sites was 6.3%. The patient questionnaire confirmed that this method can be done without any pain.

Conclusion: We confirmed that extracted IG using MIET correlated well with the IG measured by CGM. Our convenient and painless monitoring system without blood sampling could be an excellent tool for a better understanding and management of postprandial glycemic control.

The clinical and economic burden of type 1 diabetes in children, adolescents and adults

S. Goring¹, L. Cochrane², P. Donnan², A. Bell², D. Heather², S. Lane¹, A. Levy¹, S. Greene²

¹Oxford Outcomes Ltd., Vancouver, Canada, ²University of Dundee, UK.

Background and aims: Type 1 diabetes (T1D) represents approximately 10% of the global prevalence of diabetes and imposes a substantial burden on the health care system. We measured the clinical and economic burden of T1D as a necessary platform from which to plan effective health care strategies. The objectives were to estimate: 1) the direct medical costs of T1D; and 2) the proportion of subjects achieving glycaemic control, among children (8 to 12 years), adolescents (13 to 18 years) and adults (19 to 35 years).

Materials and methods: We designed a retrospective population-based cohort study of insulin-dependent subjects using clinical and administrative data held in the Health Informatics Centre, Tayside, Scotland (2000–2008). Subjects who received insulin for less than nine months or an oral antidiabetic prior to initiating insulin were excluded. We estimated the mean annual direct medical cost of T1D-related resource utilization (diabetes clinic visits, eye and foot screening, hospitalizations, laboratory tests, insulin, and glucose testing strips). Sub-optimal glycaemic control was defined as HbA1c > 7.5% for children and adolescents and HbA1c > 7% for adults. Poor glycaemic control was defined as HbA1c > 9.5%. Descriptive statistics were calculated by year and stratified by age.

Results: We identified a mean of 527 subjects per year with prevalent or incident T1D. The mean period prevalence per 1,000 person years was: 2.56 (children); 3.77 (adolescents); and 3.86 (adults). The mean incidence rate per 100,000 person years was: 49.6 (children); 44.5 (adolescents); and 27.0 (adults). Between 87% (adults) and 95% (adolescents) of subjects had at least one annual visit to a diabetes clinic. Most adults received annual eye and foot screening (78% and 79%, respectively); however, fewer than 5% of children used these services. The mean length of stay per hospitalization was 6.7 days for children (SD 2.2), 19.0 days (SD 8.6) for adolescents and 25.6 days (SD 16.5) for adults. Ketoacidosis was the most common reason for hospitalization, with 5.5% (adults) to 9.3% (adolescents) of individuals hospitalized annually. Between 52% (children) and 76% (adults) of subjects received annual micro-albuminuria tests, and 38% (adults) to 42% (children) of subjects received thyroid tests. The mean annual direct medical cost per person (in 2009 Great Britain Pounds) was: £2,747 (95% CI: £2,154 to £2,668) among children; £6,655 (95% CI: £5,660 to £7,170) among adolescents; and £4,023 (95% CI: £3,828 to £4,155) among adults. The largest cost driver was hospitalizations. Costs for blood glucose testing strips appeared to increase over the period. Most subjects had at least one HbA1c test per year (87% (adults) to 95% (adolescents)); however, few achieved target levels (between 10% (adolescents) and 32% (adults)) and many had poor glycaemic control (between 23% (children) and 46% (adolescents)).

Conclusion: This study provides a unique assessment of the burden of T1D among children, adolescents and adults. In the last decade, a more intensive approach to T1D management has been adopted, reflected in the rising use of blood glucose strips; however, hospital admissions remain a problem, and glycaemic control is not optimal in the majority of these subjects, particularly adolescents. Despite the current costs, newer technological therapies must be considered to achieve long-term improvement in the health of young people with T1D.

Burden of disease, cost and management of diabetes in EU5 countries

P.G. Kanavos, S. van den Aardweg, W.G. Schurer;

LSE Health and Social Policy, London School of Economics, UK.

Background and aims: Diabetes mellitus is associated with high risk of developing complications & severe comorbidities. In recent years the prevalence of Type I & II diabetes and its associated costs (esp. those related to treatment of complications and management of the disease) have risen. However, EU5 (France, Germany, Italy Spain and the UK) governments are not fully aware of the economic, health and societal implications of diabetes. The aims of this research are to identify and compare the evidence on the burden of disease,

costs (both direct and indirect), outcomes of diabetes across EU5 countries and to link costs and outcomes to the extent this is possible. It also aims to provide recommendations to policymakers.

Materials and methods: Primary data were collected through a questionnaire survey completed by researchers and clinicians, combined with structured interviews with clinicians and decision makers in the study countries; secondary data were collected from international databases, the international peer review literature and national statistics.

Results: The diabetes burden of disease is high and growing with an estimated country prevalence of between 3.6% (UK) and 8.9% (Germany). The direct costs of diabetes treatment are substantial, ranging from €5.1bn (Spain) to €42bn (Germany) per year, in total. Per patient direct costs are more comparable across countries, with some variation (€1,660 (Spain) to €5,726 (Germany)), indicating that the key driver behind total diabetes expenditure is prevalence. The total direct cost burden in the 5 study countries stands at €80 billion. In-patient care costs represent the highest component of direct costs (33–49%), followed by out-patient care (18–36%) and pharmaceuticals (including diabetes and non-diabetes drugs (20–32%). The cost of diabetes-related drugs (insulins and oral anti-diabetics) are a fraction of total costs and do not exceed 7% of the total. A significant majority of the in-patient direct costs accounts for treatment of diabetes-related complications, affecting approximately 18.3 million diabetic patients each year across the five study countries. Indirect costs, quantified in EU5 for the first time, relating to reduced productivity, absenteeism, early retirement and disability, are significant and can exceed direct costs by a factor of 2 to 1. Significant variations exist in the availability of outcomes data between countries and the quality of the relevant indicators. In some cases improvements in quality of care for diabetic patients are shown over time (Italy), whereas in others substantial discrepancies exist between the quality of care in metropolitan areas compared to rural settings (France).

Conclusion: Rising prevalence and costs of diabetes are growing concerns. Also of concern is the lack of adequate and accurate prevalence, cost estimates, particularly the indirect, and outcomes data. Therefore the true extent of the problem that diabetes poses is likely highly underestimated. Monitoring and evaluation of diabetic patients are also areas requiring attention. Diabetes poses a serious problem to all study countries in terms of its economic costs; the burden on individuals, families, national health systems, labour markets and national economies is considerable and will only increase in the future. Policymakers need to act urgently and improve funding and prioritisation of this disease and to drive enhanced preventative initiatives and co-ordinated disease management if we are ever to manage its total cost and societal impact.

Cost-effectiveness analysis of medical intervention in patients with early detection of diabetic neuropathy in a tertiary care hospital in Bangladesh

S.H. Habib;

Health Economics Unit, BADAS, Dhaka, Bangladesh.

Background and aims: The economic burden resulting from diabetic neuropathy (DN) consumes a major portion of resources allocated for health-care services. Cost-effectiveness of various interventions on DN and its complications has relatively been well explored in developed countries, but these are almost absent in developing countries. The present study was undertaken to assess the cost-effectiveness of medical intervention in patients with DN.

Materials and methods: Two hundred patients with DN, at least 1 year of follow-up, were purposively selected from Out-Patient Department of BIRDEM (tertiary diabetes care hospital), Bangladesh. Of them 100 were late in detection of DN (LDN) and 100 were detected early (EDN). The degree and extent of complications like cardiopathy, retinopathy, nephropathy and vasculopathy, treatment outcome, clinical effectiveness of interventions and direct, indirect & incremental cost of complications were calculated. Comparison was made between the groups.

Results: A total of 200 patients were considered for an average of 365 days, amounting to 656 person-years of observation in total. In LDN group, 22% had Diabetic Peripheral Neuropathy (DPN), 17% had Diabetic Autonomic Neuropathy (DAN), 11% had Diabetic Proximal Neuropathy (DPXN) & 9% had Diabetic Focal Neuropathy (DFN). In EDN group, 16% had DPN and 7% had DAN. The mean±SD fasting serum glucose of the groups (LDN & EDN respectively) was 10.1±0.4 & 6.1±0.3 mmol/l, TG was 163.7±99.4 & 155.6±94.8 mg/dl, total cholesterol was 205.5±41.6 & 103.2±34.5 mg/dl, HDL cholesterol was 56.2±20.3 & 39.0±14.1 mg/dl, HbA_{1c} was 9.2±1.5% &

6.5±1.3%, SBP was 172.5 ± 20.9 & 109.5±11.9 mmHg and DBP was 97.7±10.0 & 70.7±9.3 mmHg. About 19% patients in LDN & 36% in EDN were free of diabetic complications other than DN. In LDN & EDN, 32% and 48% had one complication, 29% and 10% had two and 20% and 6% had more than two complications respectively. The most frequent complication was cardiopathy, which affected 33% patients in LDN and 27% in EDN, followed by retinopathy 21% and 18%, nephropathy 17% and 13%, and vasculopathy 10% and 6% respectively. The average annual cost of care was US\$ 26846 (direct US\$ 17893 & indirect US\$ 8953), with an average US\$ 134 per patient. Among the average annual cost LDN consumed US\$ 18918 (US\$ 189 per patient) & EDN US\$ 7928 (US\$ 79 per patient). US\$ 13473 (50%) of costs was attributable to Drugs for both groups of which US\$ 10419 (77%) was for LDN & US\$ 3054 (23%) for EDN, US\$ 7653 (29%) to hospitalizations of which US\$ 4914 (64%) for LDN & 2739 (36%) for EDN. In case of diagnostics and visits the corresponding values were US\$ 1953 (55%) and 1580 (45%) and US\$ 1631 (75%) and 556 (25%) for LDN and EDN respectively. The annual medical costs increased with the increased number of complications from US\$ 1320 to 2296 to 3989 and to 6520 in LDN with one, two, three and more than three complications (other than DN) which is increasing at a rapid rate and US\$ 917 to 1556 to 1872 and to 2073 in EDN respectively, increasing at a diminishing marginal rate. The regression equation showed that medical cost is significantly related to complications tested in both univariate ($P < 0.0001$) & multiple linear regression analyses ($R^2 = 0.69$; $F = 81.5$, $P < 0.0001$).

Conclusion: Proper management with regular screening substantially reduces the expenditure related to care and complications of patients with DN even in a developing country. Strategies aimed at preventing DN and early detection of the onset of neuropathy will reduce medical costs in a substantial way.

1016

Direct medical cost of diabetes mellitus in Albania: a first study in hospitalised and out-patients polyclinic

B. Bezhani¹, F. Toti², K. Rrjepaj³, G. Bejtja⁴, R. Tafa¹;

¹Pharmaceutics Department, University Hospital Center "Mother Theresa",

²Service of Endocrinology & Metabolic diseases, University Hospital Center "Mother Theresa", ³Ministry of Health, ⁴Institute of Public Health, Tirana, Albania.

Background and aims: The burden of Diabetes Mellitus is increasing rapidly worldwide. The continuous prevalence raise of Diabetes is another factor influencing the share of diabetes cost in the health expenses of developed and developing countries. The aim of our study is to determine the direct cost per patient and the overall cost of diabetes mellitus in a group of Albanian diabetic adults.

Materials and methods: A retrospective, observational study, based on clinical audit through the analysis of the direct cost for hospitalized patients and a group of out-patients, followed in a polyclinic in Tirana. Cost was expressed only as direct means (drugs, laboratory tests, doctors, hospitals, health care). Data used for these calculations come from two sources: 1). From the individual medical records of the diabetic patients of out-patient polyclinic Nr.8 in Tirana (total of 92 patients), covering the period from January to November 2010. 2) The medical records of admitted patients at the Service of Endocrinology, in our hospital in Tirana, for the period May-June 2010 (total of 190 patients).

Results: The direct recovery cost for a patient was 146.54€, for an average hospitalization of 7.11 days (20.61€/day). As for indirect costs or social point of view there is no data or studies available in Albania. For the out-patients, the cost of diabetes treatment and follow-up was 13.43€ per month, while the cost for diabetes complications was 34.8€ per month.

Conclusion: Our study is the first one trying to estimate the direct annual cost of diabetes in Albania. We estimated the direct cost for hospitalized and out-patients with diabetes. Diabetes complications (acute and chronic) increase two to three fold the cost of Diabetes treatment. The diabetes' economic burden is significant and it's comparable to results from other countries. For indirect costs or social point of view there is no data or studies available.

1017

Costs and clinical outcomes after 24 months of insulin therapy in patients with type 2 diabetes: results from the TREAT study

M. Benroubi¹, H. Schmitt², S. Cleall³, K. Aloumanis⁴, L.J. Lee⁵, TREAT Study Investigators;

¹Polyclinic General Hospital, Athens, Greece, ²Eli Lilly and Company, Brussels, Belgium, ³Eli Lilly and Company, Windlesham, UK, ⁴Eli Lilly and Company, Athens, Greece, ⁵Eli Lilly and Company, Indianapolis, USA.

Background and aims: Insulin treatment remains a challenge in daily clinical practice. TREAT was a prospective 24-month observational study in patients (pts) with type 2 diabetes (T2D) initiating insulin, in a routine clinical setting, in 5 countries. The objectives of the study were to assess the costs associated with insulin treatment, describe starter insulin regimens and changes over 2 years as well as metabolic outcomes.

Materials and methods: Data on disease, patient characteristics, and medications were collected at baseline, and medications, clinical, and economic outcomes at 3, 6, 12, 18 and 24 months after insulin initiation. The association of patient and disease characteristics with change of therapy was assessed using logistic regression.

Results: A total of 985 pts were enrolled: Greece (GR, 205), Portugal (PT, 165), Romania (RO, 207), Sweden (SE, 178), and Turkey (TR, 230). Retention was good, with data available for 766 pts at baseline and 755, 725, 696, 658, 629 at 3, 6, 12, 18 and 24 months, respectively. Mean age at baseline was 60.6 years and time since diagnosis, 10.2 years. Mean (SD) total cost of T2D care over 24 months was: 2642€ (1054) for GR, 2630€ (1664) for PT, 1169€ (446) for RO, 3142€ (2284) for SE and 1230€ (499) for TR. At baseline, 49% of pts started with a long/intermediate acting (Long) insulin, 41% with mixtures (Mix), 7% with basal-bolus (Bas-Bol), and 2% short-acting only. The percentages for each respective regimen by country were GR (65%, 29%, 4%, 1%), PT (56%, 43%, 1%, 0%), RO (44%, 42%, 7%, 6%), SE (59%, 35%, 5%, 1%), TR (28%, 53%, 16%, 2%). There were few changes in insulin regimens over 24 months, with 81% of patients having no other insulin prescribed. Initial treatment with Long insulin was positively associated with prescription of additional insulins ($p=0.004$). Blood glucose monitoring was performed in 78% of pts at baseline and 94% at 24 months. The percentage of pts reporting hypoglycemic episodes was approximately 20% at all visits with about 90% resolved without assistance. Evolution of HbA1c is described in Table 1. At 24 months, 33.9% of pts achieved an HbA1c $\leq 7.0\%$ and 54.0% $\leq 7.5\%$. Mean total daily insulin dose was 26.0 U (0.32 U/kg) at baseline and increased to 38.9 U (0.46 U/kg) at 24 months. Mean weight was 82.4 kg at baseline and 85.6 kg at 24 months. Similarly, BMI increased from 29.9 to 31.1 kg/m².

Conclusion: The total mean cost varied among countries, ranging from 1169€ for RO to 3141€ for SE. HbA1c at baseline was relatively high, indicating late initiation of insulin. Different insulin regimens were used at initiation and varied across countries. There was a significant lowering of mean HbA1c over time observed in all initiation regimens.

Table 1: Evolution of HbA1c.

Mean HbA1c	All patients	Long	Mix	Bas-Bol	GR	PT	RO	SE	TR
Baseline	9.5%	9.0%	10.1%	10.2%	8.9%	9.6%	9.8%	7.9%	10.7%
24 months	7.5%	7.5%	7.5%	7.3%	7.2%	7.9%	8.0%	6.6%	7.6%

Direct costs of care and clinical outcomes in patients with type 2 diabetes switching between short-acting human insulin and rapid-acting insulin analogues

S. Cleall¹, M. Reaney¹, N. Tentolouris², K. Cypryk³, U. Petzinger⁴, V. Koivisto⁵, M. Jecht⁶;

¹Eli Lilly and Co, Windlesham, UK, ²Laiko General Hospital, Athens, Greece, ³Medical University, Lodz, Poland, ⁴Accovion GmbH, Eschborn, Germany, ⁵Lilly Deutschland GmbH, Bad Homburg, Germany,

⁶Gemeinschaftskrankenhaus Havelhöhe, Berlin, Germany.

Background and aims: As compared to human insulin, rapid acting insulin analogues reduce postprandial hyperglycemia, reduce the injection-mealtime interval, reduce severe hypoglycemia and may decrease HbA1c to a greater extent. However, insulin analogues are more expensive than human insulins.

The SWING study assessed direct treatment costs, glucose control, satisfaction and quality of life in patients following switches from short-acting human insulins to rapid-acting insulin analogues (H-A) or vice versa (A-H).

Materials and methods: SWING was an observational, prospective, multicentre, 12-month study performed in 9 European countries (Austria, Czech Republic, Germany, Greece, Poland, Romania, Slovakia and Turkey). Adults with type 2 diabetes (T2D) were invited to participate when they were switching insulin type (H-A or A-H) in the course of normal clinical care. Data were collected at a baseline visit (switch) and at approximately 3, 6 and 12 months post-switch. Analysis was mainly descriptive.

Results: 2389 patients switched H-A (n=2203) or A-H (n=186) insulins (another 603 enrolled but without eligible switch). Mean (SD) baseline data (H-A/A-H): age 60.9(11.1)/59.5(11.0) yrs, T2D duration 12.7(8.3)/11.4(7.2) yrs, HbA1c 8.6(1.6)/8.9(1.6)%, BMI 30.6(5.2)/30.9(5.5) kg/m². Overall, 2103 (88%) of the patients were taking at least 1 concomitant medication. The most frequently cited reason for the switch was 'lack of effect' (74.8% H-A, 62.9% A-H). Mean (SD) direct diabetes-related costs (standardised to account to variable visit schedules) were €548.7 (865.8) 6 months prior to switch, €625.6 (1474.9) at 0-6 months and €568.6 (590.7) 6-12 months following switch for H-A, and €544.5 (421.0), €481.0 (301.5) and €461.6 (335.0) for A-H, respectively. Mean direct cost increases were observed in H-A cohorts at 0-6 months while decreases were observed in A-H cohorts in most countries. Absolute standardised values differed between countries (eg mean [SD] 0-6 months highest in Germany [n=200] €1605.6 [4455.0], and lowest in Turkey [n=81] €343.7 [145.6]). Mean (SD) HbA1c decreased over 12 months: -1.08% unit (1.53% unit) H-A, -1.17% unit (1.45% unit) A-H. Proportion with an HbA1c of $\leq 7\%$ at 12 months was 34.8% H-A, and 30.4% A-H. No clinically important changes in mean BMI, blood pressure or triglycerides. The reported incidence of hypoglycaemia (recalled over the preceding 6 months) decreased from baseline (40.1% H-A, 39.8% A-H) to 12 months post-switch (28.5% H-A, 28.6% A-H), as did the mean (SD) number of episodes among those who did have hypoglycaemia (7.7[8.7]-3.6[4.1] H-A, 7.6[7.5]-5.5[4.3] A-H). There were no clinically meaningful changes from baseline in mean quality of life or treatment satisfaction questionnaire scores.

Conclusion: There were only small changes in mean direct diabetes-related costs (following adjustment for time interval) or patient-reported outcomes in patients switching in either direction between rapid-acting insulin analogues and short-acting human insulin. However, mean HbA1c and incidence of hypoglycaemia did improve following switch. The extent to which this observation can be attributed to therapeutic switch is unclear.

Clinical and economic outcomes in patients with type 2 diabetes initiating insulin glargine using disposable pen vs exenatide

O. Baser¹, W. Wei², E. Baser¹;

¹STATinMED Research, Ann Arbor, USA, ²sanofi-aventis US, Bridgewater, USA.

Background and aims: Initiation and acceptance of insulin therapy for type 2 diabetes mellitus (T2DM) is limited, partly due to perceived complexity that may reduce adherence and increase risk of hypoglycemia. Insulin pens may help enhance patient acceptance of insulin therapy and facilitate diabetes management. Evaluate the clinical and economic outcomes in patients with T2DM who failed oral antidiabetic drug (OAD) therapy and initiated either insulin glargine with disposable pen (GLAR Pen) or exenatide (EXE Pen).

Materials and methods: This retrospective study used data from a large US managed care claims database and included T2DM patients initiating treatment with the GLAR Pen or EXE Pen between 2006 and 2009 who were aged ≥ 18 , treated with an OAD only with hemoglobin A1c (HbA_{1c}) $> 7\%$ and continuously enrolled in the health plan ≥ 6 months before and 12 months after initiation. Propensity score matching with baseline sex, age, region, health plan, comorbidity, HbA_{1c}, treatment, health care utilization and cost removed observed baseline treatment-group differences. Primary study endpoints included treatment persistence, HbA_{1c}, health care utilization, and cost during the 1-year follow-up period and were compared between treatment groups.

Results: A total of 2339 patients were included in the study (GLAR Pen: 381; EXE Pen: 1958); 626 patients were in the 1:1 matched cohort with no significant differences in baseline characteristics between groups (54% male; mean age 54 years; HbA_{1c} 9.2%). At the end of 1-year follow-up, patients in the GLAR Pen group were significantly more persistent in treatment compared with the EXE Pen group (48% vs 15% in persistence rate and 252 vs 144 days in persistent days, both $p<0.001$, respectively). They also had sig-

nificantly lower HbA_{1c} at the end of follow-up (8.02% vs 8.32%, $p=0.042$) and higher HbA_{1c} reduction from baseline (-1.23% vs -0.92%, $P=0.038$). There were no significant differences in hypoglycemia rates and overall diabetes-related health care utilization and cost. Compared with the EXE Pen group, patients using the GLAR Pen had significantly higher diabetes-related outpatient (\$1673 vs \$1473, $P=0.033$) and diabetes supply (\$282 vs \$161, $P<0.001$) costs, although these were offset by significantly lower diabetes pharmacy cost (\$2106 vs \$2438, $p=0.001$).

Conclusion: This study suggests that in the real world setting among T2DM patients who failed OADs, initiation of GLAR Pen instead of EXE Pen may be associated with greater persistence and improved clinical outcomes without increased hypoglycemia or cost. These findings need to be confirmed in further clinical studies.

1020

Real-world clinical and economic outcomes in patients with type 2 diabetes initiating glargine disposable pen vs. insulin detemir disposable pen in a US managed care setting

L. Xie¹, W. Wei², C. Pan³, J. Du¹, O. Baser¹;

¹STATinMED Research, Ann Arbor, ²sanofi-aventis US, Bridgewater, ³PRO Unlimited, Boca Raton, USA.

Background and aims: Real-world data comparing outcomes of patients with type 2 diabetes mellitus (T2DM) initiating different insulin regimens would assist with treatment decisions and help optimize the management of T2DM. We compared clinical outcomes and healthcare costs following initiation of insulin glargine disposable pen (GLA-P) or insulin detemir disposable pen (DET-P) in T2DM patients.

Materials and methods: A retrospective cohort study was conducted using IMPACT, a US national managed care claims database (Jul 2006-Sep 2010). Patients were included if they were diagnosed with T2DM, aged 18-79 yrs, had HbA_{1c} data at baseline and end of 1-yr follow-up, were on ≥ 1 oral antidiabetics (OAD) or glucagon-like peptide-1 (GLP-1) medication but no insulin before initiation of GLA-P or DET-P. Patients had to be continuously enrolled in a health plan for 6-month pre- (baseline) and 12-month post GLA-P or DET-P initiation (follow-up). 1:1 propensity score matching was applied to patients in each cohort using their baseline demographic, comorbidity, HbA_{1c}, OAD or GLP-1 medication use, healthcare utilization and cost data (table). Treatment persistence and adherence, HbA_{1c} at the end of 1-yr follow-up, hypoglycemia events, and healthcare costs during the 1-yr follow-up were compared between the cohorts.

Results: A total of 1,682 patients were identified, 1016 (60.4%) initiating GLA-P and 666 (39.6%) initiating DET-P. After propensity score matching, each cohort contained 640 patients and they were well balanced (mean age 55.0 vs. 54.8 yrs; male 55.9 vs. 58.0%; CCI 0.6 vs. 0.6, HbA_{1c} 9.4 vs. 9.4%; all $P>0.4$). During follow-up, patients initiating GLA-P were significantly more likely to be persistent and adherent with treatment vs. those initiating DET-P (table). The average daily consumption (DAICON) dose was lower in the GLA-P group. Over the last quarter of the 1-yr follow-up, fewer GLA-P patients switched to DET-P vs. those switching from DET-P to GLA-P (1.4 vs. 5.9%). At the end of 1-yr follow-up, initiation of GLA-P was associated with lower HbA_{1c} and higher reduction of HbA_{1c} from baseline, without a significant difference in the number of patients having hypoglycemia events during follow-up (table). Patients in the GLA-P and DET-P cohorts had similar total and DM-related healthcare costs (table). Population-wise, for each 1% reduction in HbA_{1c} from baseline to the end of follow-up, the mean DAICON and healthcare costs were lower in the GLA-P vs. the DET-P group (DAICON: 23.6 vs. 31.8 units, diabetes-related cost: \$5,732 vs. \$6,287, total cost: \$13,059 vs. \$15,350, respectively).

Conclusion: This real-world study demonstrated that patients initiating GLA-P were more likely to persist and adhere with treatment, with better glycemic control. Furthermore, the initiation of GLA-P was more cost effective compared with DET-P.

Follow-up of the matched cohorts	GLA-P (n=640)	DET-P (n=640)	P-value
Persistence, n (%)	263 (41.1)	200 (31.3)	0.0002
Persistence days, days \pm SD	236.3 \pm 118.8	212.8 \pm 114.9	0.0003
Adherence measured by Adjusted MPR, mean \pm SD	0.7 \pm 0.3	0.6 \pm 0.3	0.0001
Adherence measured by Adjusted MPR ≥ 0.8 , n (%)	309 (48.3)	266 (41.6)	0.0157
DAICON, mean \pm SD	29.0 \pm 19.1	31.8 \pm 23.3	0.0342
HbA _{1c} at the end of 1-year follow-up, mean \pm SD	8.1 \pm 1.6	8.4 \pm 1.8	0.0260
Change in HbA _{1c} from Baseline, mean \pm SD	-1.23 \pm 2.09	-1.00 \pm 2.03	0.0467
Patients with Hypoglycaemia events, n (%)	49 (7.66)	36 (5.63)	0.1445
Total healthcare costs (US\$), mean \pm SD	16,063 \pm 20,270	15,350 \pm 20,291	0.5293
Diabetes-related costs (US\$), mean \pm SD	7,050 \pm 12,076	6,287 \pm 6,910	0.1656

Medication persistence was defined as the % of patients remaining on therapy without discontinuation or switching during the 1-yr follow-up.

Medication adherence was measured using the medication possession ratio (MPR) adjusted for differences in insulin device package size during the 1-yr follow-up.

Hypoglycemia was defined as a health care encounter with a diagnosis code for hypoglycemia (ICD-9 code 250.8; 251.0; 251.1; or 251.2) during the 12-month follow-up period.

GLA-P, insulin glargine disposable pen; DET-P, insulin detemir disposable pen, MPR, medication possession ratio, DAICON, daily average consumption.

In the US-setting, blood glucose testing represents 20% of total pharmacy diabetes-related costs in patients with diabetes on an insulin regimen

T.E. Christensen¹, J. Yeaw², W. Lee³, M. Aagren⁴;

¹Novo Nordisk A/S, Søborg, Denmark, ²IMS Consulting, Redwood City, USA, ³IMS Health, Falls Church, USA, ⁴Novo Nordisk Inc, Princeton, USA.

Background and aims: For patients with insulin-requiring diabetes, Self-Measured Blood Glucose (SMBG) is an essential part of titrating and monitoring an insulin-based treatment regimen. However, little is known about the real-life frequency and costs associated with SMBG in relation to the specific regimen, and what SMBG expenditure is compared to other treatment costs.

Materials and methods: The present study used the IMS LifeLink Health Plan Claims Database, which have medical and pharmacy claims for more than 71 million unique patients from 102 health plans across the US. Patients were included in the analysis if they: had 2+ prescriptions for insulin (any type) during the period from January 1, 2007 through June 30, 2009; had 18+ months of data (6 months for baseline data + 12 months for outcomes data); had a diagnosis for type 1 or type 2 diabetes; were persistent with insulin therapy throughout the 12-month follow-up period. Patients were excluded if: they were <4 years old; they had incomplete claims data; their insulin type could not be adequately categorised.

Results: A total of 74,936 patients met the inclusion and exclusion criteria. All analyses were stratified by gender, age group, type of diabetes, insulin regimen (basal only, premixed, basal-bolus), type of health plan/payer, geographic region, total healthcare costs for all conditions during the patient's 6-month baseline period, Charlson Comorbidity Index, daily average consumption of insulin. The analysis demonstrated that SMBG (strips, lancets etc.) constitutes 20.2% (\$602 of \$2,975) of the total annual diabetes-related pharmacy costs (strips, insulin, needles, oral antidiabetic drugs etc.). Relative cost of SMBG was 15.3% (\$399 of \$2607) for basal only, compared with 22.2% for basal/bolus (\$812 of \$3666) and 15.1% for pre-mixed insulin (\$395 of \$2617).

Conclusion: This study shows that SMBG constitutes a large part of the treatment costs for insulin users. New generations of insulin used in regimens with simpler titration are warranted in order to enable relevant cost savings.

Estimating the impact of different methods of utility assessment on the value of interventions in type 2 diabetes

A. Lloyd¹, V. Foos², C. Donatti¹, D. Grant¹, W. Herman³;¹IMS Health, London, UK, ²IMS Health, Basel, Switzerland, ³University of Michigan, Ann Arbor, USA.

Background and aims: Methodological approaches to estimating utility in the presence of multiple co-morbidities include the 'minimum' approach, which employs the value of the condition with the lowest individual utility score and the 'multiplicative' approach, which employs the arithmetic product of utility scores as a proportion of full health. Health Technology Assessment (HTA) guidelines do not clearly recommend which method is preferred. This is of particular concern in the measurement of utility in diabetes as patients often experience multiple simultaneous complications. This investigation compares the estimated benefit of interventions using the multiplicative and minimum approaches to calculate patient utility.

Materials and methods: The IMS CORE Diabetes Model (CDM) is a well documented and validated computer simulation model for types 1 and 2 diabetes. The CDM was used to replicate two well known studies in type 2 diabetes, one investigating intensive glucose lowering therapy in newly diagnosed patients, average age 52 years (UKPDS cohort) and another in patients with more advanced disease, average age 62 years (ACCORD cohort). Expected quality adjusted life years (QALYs) in each arm and the benefit of therapy were calculated for each study using minimum and multiplicative utility calculation. To explore the possible impact on HTA we hypothesised an intervention that increased treatment cost by an arbitrary €5,000 over the patient's lifetime, and tested how much the incremental cost per QALY gained (CPQ) would be affected by the choice of utility calculation method. The model was run over a lifelong time horizon without discounting.

Results: Table: Expected outcomes in QALYs per patient treated

	UKPDS cohort			ACCORD cohort		
	Conven-tional therapy	Intensive therapy	Benefit	Conven-tional therapy	Intensive therapy	Benefit
QALYs per patient (minimum approach)	14.13	14.55	+0.42	8.09	8.34	0.25
QALYs per patient (multiplicative approach)	13.62	14.11	+0.49	7.35	7.68	0.33
Difference (multiplicative vs minimum, %)	-3.6%	-3.0%	+16.7%	-9.1%	-7.8%	+32.0%

The estimated CPQ for the hypothetical intervention in the UKPDS cohort was €11,900 using the minimum approach and €10,200 using the multiplicative approach and in the ACCORD cohort was €20,000 using the minimum approach and €15,150 using the multiplicative approach.

Conclusion: Compared with the minimum approach, the multiplicative approach generated lower estimates of total lifetime QALYs but larger estimated benefits from therapy. These effects are most pronounced in patients with more advanced disease at baseline. These differences are large enough to alter cost-effectiveness ratios appreciably and hence potentially impact the outcomes of HTA.

Effects of basal bolus vs basal plus insulin regimens on weight in patients with type 2 diabetes

D. Raccach¹, L. Gao², R. Berria²;¹Hôpital Sainte Marguerite, Marseille, France, ²sanofi-aventis US, Bridgewater, USA.

Background and aims: Patients with type 2 diabetes (T2D) may require prandial insulin injections in addition to basal insulin, but optimal regimens for individual patients are difficult to determine.

Materials and methods: This sub-analysis of a randomized controlled study compared the 1-year efficacy and safety of insulin glargine (GLAR) plus 1, 2, or 3 daily injections of insulin glulisine (GLU) in patients with or without weight gain. Patients were grouped according to those who received 1 (n=114), 2 (n=128), or 3 (n=209) GLU injections in addition to GLAR and oral medications; results within each injection category were stratified by patients who gained weight vs those with no weight gain (or weight loss). Baseline demographics and clinical characteristics were similar among the 3 groups, except for a higher percentage of males and lower mean HbA_{1c} in the 1 GLU group vs groups 2 or 3.

Results: Baseline demographics were similar among groups, except for more males (49% vs 38% and 36%) and lower mean A1C (8.22% vs 8.47% and 8.53%) in group 1-GLU vs groups 2 or 3. Overall, at week 52, 3-GLU patients were more likely to reach A1C goal ($\leq 7.0\%$) vs 1-GLU patients, (26% vs 17%, $P=0.02$) but were not more likely to gain weight (1.9 kg vs. 1.3 kg, $P=NS$). At week 52, 38/114 (33.3%) and 66/209 (31.6%) patients in 1-GLU and 3-GLU, respectively, maintained or lost weight (mean[SD] 2.0[2.2] kg and 1.9[1.9] kg, respectively); 26.3% and 25.8% of these patients achieved A1C $\leq 7.0\%$ (Table). Patients receiving 1-GLU who maintained or lost weight had 3X-greater odds of achieving A1C $< 7.0\%$ vs patients who gained weight (26.3% vs 10.5%, $P=0.04$). Incidence and event rates of hypoglycemia with SMBG < 50 mg/dL were similar among the 3 groups (1-GLU, 2-GLU and 3-GLU incidence [%]: 21.9, 22.7, 15.3 and event rate [events/pt year]: 0.58, 1.04, 0.60, $P=NS$).

Conclusion: The results of this analysis suggest that patients with a basal plus insulin regimen can achieve glycemic goals while also maintaining or losing weight. Increasing the number of daily GLU injections from 1 to 3 does not significantly increase weight gain or risk of hypoglycemia.

Short term impact of insulin therapy on cardiac function and lipid metabolism in patients with type 2 diabetes mellitus: a magnetic resonance imaging and spectroscopy study

D. Jankovic¹, Y. Winhofer¹, M. Krssak², M. Promintzer-Schifferl¹, E. Wohlschlaeger-Krenn¹, C.-H. Anderwald¹, A. Luger¹, M. Krebs¹;
¹Department of Internal Medicine III, ²Department of Radiodiagnostics, Medical University of Vienna, Austria.

Background and aims: Patients with diabetes are at risk for specific myocardial disease (diabetic cardiomyopathy), which is causally related to increased myocardial lipid (MYCL) accumulation. In type 2 diabetes mellitus (DM2) intensive glucose lowering therapy has been associated with increased mortality of unknown cause. Thus, the aim of the present study was to assess whether induction of insulin therapy in patients with DM2 and insufficient metabolic control under oral anti-diabetic therapy affects cardiac lipid content and function.

Materials and methods: Magnetic resonance imaging and spectroscopy (MRI/MRS) measurements were performed twice in 9 patients with DM2 (4 female; age: 59 ± 10 years; BMI: 29.9 ± 5.1 kg/m²; HbA_{1c}: 11.2 ± 1.4 %) before and after 10 days of standardized insulin treatment. MYCL content and function were measured by ECG-triggered and breath movement navigated localized ¹H single voxel MRS and dynamic MRI, respectively. Intra-hepatic lipids were determined by ¹H MRS.

Results: Insulin therapy was associated with a 1,6-fold increase of MYCL (0.43 ± 0.46 vs. 0.69 ± 0.37 % of water signal; $p = 0.038$), while intra-hepatic lipid content did not change. In the short-term cardiac lipid accumulation was not associated with changes in left-ventricular systolic (ejection fraction [$p = 0.767$]; end-systolic volume [$p = 0.859$]) or diastolic (end-diastolic volume [$p = 0.953$]) function.

Conclusion: The induction of insulin therapy in patients with DM2 and bad metabolic control is associated with significant myocardial lipid accumulation but not with acute changes in left ventricular function. However, long term adverse effects of myocardial steatosis cannot be excluded.

Mechanism of action of inhaled insulin Exubera[®] to normalise the fasting plasma glucose concentration in type 2 diabetic patients

R.J. Mehta^{1,2}, A. Ricotti², B. Balas², A. Gastaldelli², R.A. De Fronzo², D. Tripathy²;

¹Western University of Health Sciences, Pomona, ²The University of Texas Health Sciences Center at San Antonio, San Antonio, USA.

Aim: To examine the mechanism(s) via which Exubera, a “short acting” inhaled insulin administered three times daily, reduces the fasting plasma glucose (FPG) concentration which is primarily determined by the rate of endogenous (primarily hepatic) glucose production throughout the sleeping hours.

Methods: Ten T2DM subjects (age= 55 ± 3 yrs; BMI= 33 ± 1.4 , FPG= 211 ± 15 mg/dl; HbA_{1c}= 10.0 ± 1.2 %) completed 16 weeks of treatment with Exubera. At baseline and after 16 weeks subjects received: (i) an Oral Glucose tolerance test (OGTT) with plasma glucose, C-peptide and free fatty acid concentrations measured every 15 minutes, (ii) 24 hour plasma glucose profile using continuous glucose monitoring device (Medtronic, USA) (iii) hepatic glucose production ($3\text{-}^3\text{H-glucose}$).

Results: Following 16 weeks of Exubera therapy, body weight increased from 99 ± 5 to 101 ± 4 kg ($p < 0.05$). Fasting (211 ± 15 to 140 ± 11 mg/dl, $p < 0.005$) and 2-hour OGTT glucose (309 ± 9 to 264 ± 11 mg/dl, $p < 0.05$), the glucose AUC during OGTT, all decreased significantly ($34,847 \pm 1039$ to $28,586 \pm 1628$, $p < 0.05$). HbA_{1c} decreased from 10.0 ± 0.8 to 7.3 ± 0.7 , $p < 0.05$). The 24-hour plasma glucose profile was markedly decreased ($p < 0.001$) following Exubera treatment with a greater decline in the postprandial compared to fasting glucose. Fasting (0.662 ± 0.09 vs. 0.594 ± 0.08 mM) and post OGTT plasma free fatty acid concentration (0.319 ± 0.08 to 0.242 ± 0.08 mM) decreased significantly following treatment with Exubera. Plasma triglyceride (193 ± 47 to 103 ± 20) decreased, while plasma HDL concentration increased (33 ± 3.1 to 52 ± 5.3 , $p < 0.05$) following Exubera. LDL and total cholesterol did not change significantly. The basal rate of hepatic glucose production ($3\text{-}^3\text{H-glucose}$) decreased significantly (9.2 ± 0.9 vs. 6.9 ± 0.9 $\mu\text{mol/kg/min}$, $p = 0.03$) after 16 weeks of Exubera therapy. No significant difference was observed in measures of insulin secretion following 16 weeks of Exubera. There were no serious episodes of hypoglycemia and there was no change in FEV1 following treatment with Exubera (100 ± 4.7 vs. 96 ± 7 % of predicted).

Conclusion: Sixteen weeks of Exubera treatment caused a marked improvement in glycemic control, as evidenced by decreases in fasting glucose, 2-h glucose (OGTT), HbA_{1c}, and mean 24 hr glucose profile. The improvement in glycemic control is likely secondary to Exubera's effect in decreasing hepatic glucose production.

The BeAM factor: an easy-to-determine, objective, clinical indicator for when to add prandial insulin vs continued basal insulin titration

A. Zisman¹, A. Vlainic², R. Zhou³;

¹Endocrine Center of Aventura, Miami, ²sanofi-aventis US, Bridgewater, USA, ³Medpace, Cincinnati, USA.

Background and aims: In treating type 2 diabetes (T2D), it is often unclear when titration of basal insulin is maximized and prandial insulin should be added. We propose the adoption of an easily obtained measure to assist with such treatment decisions. Ideally, basal insulin therapy should match hepatic glucose production and maintain a narrow blood glucose range, including overnight. Large differences between Bedtime and AM (“BeAM” factor) blood glucose during treatment suggests that basal insulin may have reached maximal titration and that prandial insulin should be introduced to correct for PPG excursions to help achieve target HbA_{1c}.

Materials and methods: BeAM was examined using data pooled from 6 randomized controlled trials of insulin glargine vs a comparator added to oral antidiabetic drug (OAD) therapy in adults with T2D. Insulin was titrated to achieve FG ≤ 100 mg/dL. 1699 patients were included; 42% female, 95% white, mean age 59 (9) years, HbA_{1c} 8.7%, and duration of diabetes 9 (6) years.

Results: BeAM increased over 24 weeks of treatment (overall, BeAM increased from 25 mg/dL at baseline to 41 mg/dL at week 24, change of 16 mg/dL). Mean change in BeAM was greater in patients receiving basal insulin (Glargine or NPH, $n=1261$) vs other treatments (OADs or other insulin, $n=438$, mean change of 27 mg/dL vs -15 mg/dL, respectively, LS mean difference 36.5 mg/dL, $P < 0.0001$). Regardless of treatment, patients nearing target FG ≤ 100 mg/dL had an even greater increase in BeAM; of patients achieving pre-breakfast FG > 80 and < 120 mg/dL after 24 weeks ($n=431$), BeAM increased from 30 mg/dL at baseline to 58 mg/dL at week 24 (mean change of 32 mg/dL). The proportion of patients with BeAM > 50 mg/dL increased from 27% at baseline to 47% at week 24. In all 1699 patients and in those on basal insulin, a larger BeAM at week 24 was associated with reduced likelihood of attaining HbA_{1c} $\leq 7.0\%$ ($r^2=0.160$ all; $r^2=0.187$ BI; $P < 0.0001$ for both, Table) and increased risk of nocturnal ($r^2=0.152$, $P < 0.0001$), but not overall, hypoglycemia. Patients on basal insulin with a BeAM > 55 mg/dL were less likely to approach HbA_{1c} $\leq 7.0\%$. (Table)

Conclusion: This analysis suggests that patients on basal insulin with a BeAM factor > 55 mg/dL may not benefit from continued basal insulin titration and addition of prandial insulin should be considered to correct glucose excursions and achieve glycemic goals.

Relationship of BeAM and HbA_{1c} at 24 weeks

	HbA _{1c}	BeAM Least squares mean (SE)	P value difference from < 6.5

Achievement of glycaemic control by patients initiating basal insulinM. Aagren¹, N. Wu², P. Rao², L. Boulanger²;¹Novo Nordisk, Princeton, USA, ²United BioSource Corporation, Lexington, USA.

Background and aims: While many patients with type 2 diabetes mellitus (T2DM) achieve glycaemic goals with lifestyle modifications and the use of oral antidiabetic drugs (OADs), most patients will eventually require the inclusion of insulin in their treatment regimen to reach adequate control. This study identified T2DM patients initiating basal insulin and assessed the proportion of patients treated to goal and the time to reach goal.

Materials and methods: Electronic medical records (EMR) dated January 2005 through August 2010 were assessed from the General Electric EMR Database. Patients with T2DM who initiated basal insulin between July 2005 and August 2009 were selected, with initiation defined as no prescription record of insulin in the prior 15 months. Patients were grouped into five cohorts (glycated hemoglobin [A1C] $\leq 6.5\%$, $6.5\% < A1C \leq 7\%$, $7\% < A1C \leq 8\%$, $8\% < A1C \leq 9\%$, and $A1C > 9\%$) based on A1C measured within 90 days prior or up to 14 days following insulin initiation. Demographic characteristics, comorbidities and OAD use were assessed based on data from the 15 months prior to insulin initiation. The proportion of patients achieving A1C $\leq 7\%$ ("goal") within one year after initiation were estimated; the average time to achieve goal was estimated using the Kaplan-Meier method. Changes of A1C levels pre- and post- insulin initiation were calculated; statistical significance of difference from 0 was detected by pair-wise t-tests. Differences in means between cohorts were detected by analysis of variance tests, and trends in the proportions across A1C cohorts were detected by Mantel-Haenszel tests.

Results: Of the 13,494 T2DM patients who initiated basal insulin, 52.0% were 60+ years old and 50.6% were female. At baseline, more than half of the patients had A1C $> 8\%$, and 60% were obese. Sulfonylureas were the most commonly used OADs (53.4%), followed by metformin (52.6%). Usage increased significantly ($p < 0.01$) with increasing baseline A1C. Most patients (88.3%) initiated basal analogs (insulin detemir or insulin glargine), 11.0% initiated NPH, and 0.7% received prescriptions for both. The proportion of patients initiating NPH decreased from 19.0% to 8.1% across the A1C cohorts ($p < 0.01$). During the 12 months post insulin initiation, the proportion reaching goal decreased from 88.4% for the A1C ≤ 6.5 cohort to 29.0% for the A1C > 9 cohort, while average time to achieve goal increased from 199 days (95% confidence interval [CI]: 194–204) to 313 days (95% CI: 310–315) (Log-rank test: $p < 0.01$). After basal insulin initiation, mean A1C decreased significantly, by 0.41% (standard deviation [SD]: 0.96, $p < 0.01$) to 2.8% (SD: 2.3, $p < 0.01$) in cohorts with baseline A1C $> 7\%$.

Conclusion: After initiating basal insulin, a higher proportion of patients with T2DM with a lower baseline A1C reached the target of A1C $\leq 7\%$, and took fewer days to do so. Among patients whose baseline A1C were below target, the natural drift in A1C may offset the treatment effect of basal insulin, and thus result in a follow-up A1C above the 7% goal in some cases.

	Cohorts by baseline A1C value					p value
	All patients (n=13,494)	A1C ≤ 6.5 (n=1,228)	6.5 < A1C ≤ 7 (n=1,049)	7 < A1C ≤ 8 (n=3,178)	8 < A1C ≤ 9 (n=2,737)	A1C > 9 (n=5,302)

Outcomes associated with insulin therapy discontinuation after hospital discharge in patients with type 2 diabetes initiated on insulin during hospitalisationS. Zhou¹, E. Wu², A. Peng Yu², M. Lu³, H. Sharma², T. Graf³;¹sanofi-aventis US, Bridgewater, ²Analysis Group, Boston, ³Geisinger Health System, Danville, USA.

Background and aims: In the real world, regardless of HbA_{1c} levels during hospitalization, patients may discontinue insulin therapy (INS) after hospital discharge. However, there is a lack of understanding on the clinical outcomes

associated with insulin discontinuation post hospital discharge. This study investigated the clinical outcomes and risk of hospital re-admission associated with discontinuation of INS after hospital discharge among patients with type 2 diabetes (T2DM) who initiated INS during hospitalization.

Materials and methods: Adult T2DM patients newly initiated on INS during a hospitalization were identified in MedMining Electronic Health Record data (from 01/2004 to 04/2010). Patients with a last recorded HbA_{1c} $\geq 8\%$ within 3 months of (or during) the hospital stay were included. Outcomes were compared between patients with INS continuation after the hospitalization (defined as an outpatient INS order within 60 days post-discharge) vs. patients with INS discontinuation. During the 12-month post-discharge, changes in HbA_{1c} were compared using t-tests and regression models. HbA_{1c} goal achievement ($< 7\%$) and hypoglycemia were evaluated using chi-square tests and logistic regression models. Time to re-admission was compared using Cox proportional hazard models. All regression models controlled for patient characteristics prior to and during hospitalization and concurrent medications received within 60 days of discharge. A subgroup analysis was performed in patients with baseline HbA_{1c} $\geq 9\%$.

Results: 180 patients with INS continuation and 552 patients with INS discontinuation were included (baseline HbA_{1c} 11.1% vs. 9.5%, respectively). During the 12-months post-discharge, patients continuing INS had greater HbA_{1c} reduction (3.4% vs. 1.5%, $P < 0.01$), higher HbA_{1c} goal achievement (41% vs. 31%, $P = 0.02$), and comparable hypoglycemia (8% vs. 5%, $P = 0.25$) vs. those with INS discontinuation. In the HbA_{1c} $\geq 9\%$ subgroup similar patterns were observed for INS continuation ($N = 146$) vs. discontinuation ($N = 277$) (baseline HbA_{1c}: 11.7% vs. 10.6%; HbA_{1c} reduction: 4.1% vs. 2.3%, $P < 0.01$; HbA_{1c} goal achievement: 44% vs. 30%, $P = 0.02$; hypoglycemia: 6% vs. 5%, $P = 0.75$). Multivariate analysis were generally consistent with descriptive findings for both the HbA_{1c} $\geq 8\%$ and $\geq 9\%$ groups (HbA_{1c} reduction: adjusted difference = 1.67% and 1.53%, both $P < 0.01$; HbA_{1c} goal achievement: odds ratio [OR] = 1.66 and 2.15, $P = 0.06$ and $P = 0.03$; hypoglycemia: OR = 1.02 and 0.91, $P = 0.97$ and 0.90; respectively). Among the HbA_{1c} $\geq 9\%$ subgroup, INS continuation was associated with lower risks of all-cause and diabetes-related hospitalizations (hazard ratio: 0.58 and 0.46 respectively; both $P < 0.05$).

Conclusion: T2DM patients who continued INS after hospital discharge had a greater HbA_{1c} reduction, a greater HbA_{1c} goal achievement, and a lower risk of hospital re-admission compared with patients with discontinued INS. Supported by: sanofi-aventis US

Outcomes following insulin therapy disruption after hospital discharge in patients with type 2 diabetesE. Wu¹, S. Zhou², A. Peng Yu¹, M. Lu¹, H. Sharma¹, T. Graf²;¹Analysis Group, Boston, ²sanofi-aventis US, Bridgewater, ³Geisinger Health System, Danville, USA.

Background and aims: In the real world setting, hospitalization may disrupt insulin therapy (INS) and lead to suboptimal care. However, there is a lack of understanding on the clinical outcomes associated with insulin disruption post hospital discharge. This study investigated clinical outcomes and urgent care use following disruption of INS after hospital discharge among patients with type 2 diabetes mellitus (T2DM) who had used INS before and during the hospital stay.

Materials and methods: 2,160 adult T2DM patients were identified with INS use within 30 days before and during a hospital stay from electronic medical records in a coordinated health care system (01/2004 to 04/2010). Outcomes were compared between 851 patients with vs. 1,309 patients without INS continuation over the first 60 days post-discharge.

Results: Compared with patients with INS disruption, patients who continued INS were younger (63 vs. 65 years, $P < 0.01$), had more frequent baseline ophthalmic complications (36% vs. 29%, $P < 0.01$), and higher blood glucose on admission (11.7 mmol/L vs. 10.4 mmol/L, $P < 0.01$). Kaplan-Meier analysis showed that patients who continued INS had significantly lower risks of all-cause re-admission compared with patients with INS disruption, which was confirmed using Cox models (see figure). INS continuation was associated with significantly lower risk of diabetes-related re-admissions (hazard ratio [HR]: 0.88; 95%CI: 0.77, 0.99) and ER visits (HR: 0.88; 95%CI: 0.78, 0.99). Patients who continued INS had greater HbA_{1c} reduction within 1 year after discharge vs. those with INS disruption (0.51% vs. 0.17%, $P < 0.01$). A similar trend was observed among patients with HbA_{1c} $\geq 7\%$ before discharge (0.75% vs. 0.42%, $P < 0.01$) which consists of 71% of the population with HbA_{1c} values. Multivariate regression analysis showed that patients with INS continuation

had a significantly higher HbA_{1c} reduction, both in the overall population (diff=0.31%, $P<0.01$) and in those patients with HbA_{1c} $\geq 7\%$ (diff=0.29%, $P<0.05$).

Conclusion: T2DM patients who continued INS after hospital discharge had greater HbA_{1c} reduction and lower risk of urgent care visits vs. patients who disrupted INS.

Kaplan-Meier curves for time to the first all-cause hospital re-admission among T2DM patients continuing vs. those disrupting insulin

Interpretation: Insulin continuers have a significantly lower risk of all-cause hospital re-admission compared with insulin discontinuers after discharge (adjusted hazard ratio: 0.82 [95%CI: 0.73, 0.93]).

Clinical characteristics and outcomes in patients with type 2 diabetes adding insulin glargine to exenatide or exenatide to insulin glargine in a US managed care setting

P. Levin¹, W. Wei², L. Wang³, O. Baser³;

¹Model Clinical Research, Baltimore, ²sanofi-aventis US, Bridgewater,

³STATinMED Research, Ann Arbor, USA.

Background and aims: Few studies have addressed the real-world efficacy or treatment persistence of insulin glargine (GLA) and exenatide (EX) in combination. This study evaluated the clinical characteristics and outcomes in patients with type 2 diabetes mellitus (T2DM) when these medications were used in combination.

Materials and methods: Using a national US insurance claims database, a retrospective study was conducted in T2DM patients aged ≥ 18 years old, who added EX to GLA (EX+GLA) or GLA to EX (GLA+EX) from 2006 to 2009 and had continuous health plan coverage 6-month pre- (baseline) and 1-year post-index (follow-up).

Results: 422 patients were included, with the majority (67%, $n=281$) in the EX+GLA cohort (mean age 53.9 yrs; 52.3% male) and 33% ($n=141$) in the GLA+EX cohort (mean age 54.2 years; 58.2% male). The EX+GLA cohort had lower HbA_{1c} than the GLA+EX cohort at baseline (see table). A significant reduction in HbA_{1c} was observed in both cohorts at follow-up. Average daily dose of glargine was 36.1 units in the GLA+EX and 43.4 units in the EX+GLA group. The mean number of hypoglycemic events increased slightly from baseline but remained low in the EX+GLA and GLA+EX cohorts (0.25 to 0.75 and 0.17 to 0.57 events per patient per year, respectively). Improved lipid profiles were observed at follow-up in both cohorts. Only small proportions of patients stayed on both drugs at the end of 1-year follow-up (EX+GLA: 11% and GLA+EX: 9.9%) but more patients stayed on GLA than EX in both cohorts (EX+GLA: 43.6% vs. 21.0%; GLA+EX cohorts: 44.0% and 23.6%, respectively).

Conclusion: This real-world study demonstrated that combination use of GLA and EX in T2DM patients with poor glycemic control was associated with significant reductions in HbA_{1c} with no significant increase in the frequency of hypoglycemia.

Baseline characteristics from 11 prospective randomised trials that predict an effective approach to starting and adjusting insulin glargine

R. Cuddihy¹, R. Bergenstal², A. Vlainic¹, M. Rimler³;

¹sanofi-aventis, US, Bridgewater, ²International Diabetes Center,

Minneapolis, ³Medpace, Cincinnati, USA.

Background and aims: Insulin glargine (GLAR) can be added to patients with type 2 diabetes (T2DM) inadequately controlled by oral agents, yet the most effective and safe starting dose or the maximum dose to reach endpoint glucose targets in a given patient is unclear. This analysis examined whether baseline characteristics can predict appropriate GLAR starting and final dosages in T2DM patients.

Materials and methods: Data were pooled from 11 prospective, 24-week, randomized, controlled trials ($N=2311$) using basal GLAR as the only insulin. Strict, predefined insulin titration algorithms were followed to achieve FPG ≤ 100 mg/dL (5.6 mmol/L).

Results: Mean age was 58.6 years, 55.8% were male, and 81.6% were white. The Table shows Week 24 weight-adjusted insulin doses, % of patients achieving HbA_{1c} $\leq 7\%$, and yearly rates of severe hypoglycemia. GLAR requirements increased in obese ($BMI > 30$) vs non-obese patients and in patients with greater baseline HbA_{1c}. GLAR requirements decreased in elderly (≥ 65 yrs) vs non-elderly (< 65 yrs) patients. Week 24 target HbA_{1c} ($\leq 7\%$) was reached by $\sim 65\%$ with baseline HbA_{1c} $< 9\%$; $\sim 40\%$ with HbA_{1c} $\geq 9\%$. Yearly event rates of severe hypoglycemia were generally low in all groups; rates were slightly higher with higher baseline HbA_{1c}. In the elderly, a 0.1 U/kg starting dose can be safely titrated to 0.3-0.4 U/kg to reach target endpoints. In the nonelderly, if HbA_{1c} is $< 9\%$ start with 0.1 U/kg and adjust to 0.4 U/kg; if HbA_{1c} is $\geq 9\%$ start with 0.2 U/kg and adjust to 0.5-0.6 U/kg.

Conclusion: While GLAR dosages should be determined by the physician based on individual patient characteristics, these baseline predictor data from a large patient pool provide clinically relevant guidelines for starting and adjusting GLAR dosages that allow patients to reach glycemic targets safely (minimizing severe hypoglycemia).

Table.				
	<65 years		≥ 65 years	
Baseline HbA _{1c}	Non-obese	Obese	Non-obese	Obese
Week 24 weight-adjusted insulin dose (U/kg) (Mean [SD])				
<9%	0.38 (0.22)	0.45 (0.25)	0.33 (0.19)	0.34 (0.17)
$\geq 9\%$	0.49 (0.25)	0.58 (0.29)	0.41 (0.21)	0.39 (0.20)
Week 24 HbA _{1c} $\leq 7\%$ (n/N, %)				
<9%	260/388 (67.0)	357/516 (69.2)	149/235 (63.4)	106/158 (67.1)
$\geq 9\%$	109/286 (38.1)	146/365 (40.0)	53/129 (41.1)	36/93 (38.7)
Severe hypoglycemia (events/year) (Mean [SD])

Proportion of patients with type 2 diabetes achieving HbA_{1c} targets without weight gain or hypoglycaemia in PREDICTIVE™: the value of earlier initiation or intensification of insulin therapy

A. Dornhorst¹, S. Sreenan², A. Liebl³;

¹Department of Metabolic Medicine, Imperial College, London, UK,

²Department of Endocrinology, Connolly Hospital, Dublin, Ireland, ³Center for Diabetes and Metabolism, Bad Heilbrunn, Germany.

Background and aims: Hypoglycaemia and weight gain frequently act as barriers to modification of regimen in type 2 diabetes (T2D), and may more than offset the benefits of HbA_{1c} reduction. Yet early action before blood glucose levels rise substantially above target levels may reduce the risk of these unwanted side effects.

Materials and methods: PREDICTIVE was a multi-national observational study evaluation of insulin detemir (IDet) use in routine clinical practice. Data from 11 European countries sub-divided by starting and subsequent regimen were used in an exploratory logistic regression analysis to identify predictors for a composite endpoint of HbA_{1c} <7% (53 mmol/mol), without weight gain or hypoglycaemia after 3 months of treatment with IDet. Logistic regression using a multivariate analysis was made using the baseline characteristics: diabetes duration; age; BMI; frequency of hypoglycaemia 4 weeks prior to study start; HbA_{1c}; and fasting blood glucose (FBG).

Results: Observations from patients with efficacy data (n=6979, missing data=255) were included in the analysis; of these patients, 1408 (21%) achieved the composite endpoint. The Table illustrates that indicators of glycaemic control (baseline HbA_{1c} and FPG) were significant predictors for patients <7% (53 mmol/mol) without side-effects when using IDet. Similarly, although to a lesser extent, BMI and experience of hypoglycaemia at baseline were also predictors, as was the duration of diabetes. Directionally, patients with lower HbA_{1c} on entering the study who then received regimen modification (either initiation or switch of insulin to IDet) benefitted more than those for whom HbA_{1c} was higher. Similarly, diabetes duration correlated with this trend, with early intervention again bringing greater benefits - lower BMI and less frequent hypoglycaemia were similarly predictors of greater benefits.

Conclusion: These data support the earlier initiation of IDet or modification of a regimen which is failing to control blood glucose levels; more timely intervention by physicians (defined here as intervention before HbA_{1c} levels rise beyond recommended target levels) may enable their patients to achieve or maintain HbA_{1c} <7% (53 mmol/mol) without weight gain or hypoglycaemia.

Table. Predictors of tight glycaemic control without hypoglycaemia or weight gain

Factor	Mean (SD)	Logistic regression p-value
Gender (female:male)	4149:3732 (53% female)	0.80
Age (years)	61.0 (10.7)	0.65
Duration of diabetes (years)	10.8 (7.2)	<0.0001
BMI (kg/m ²)	30.9 (5.7)	0.0005
HbA _{1c} (%; mmol/mol)	8.46 (1.58)% 69 (6)	<0.0001
FBG (mmol/l)	10.33 (3.13)	<0.0001
Total number of hypoglycaemic events	0.66	0.0021

Key: hypoglycaemic events were recorded as 'n' based on patient recall from the four weeks prior to baseline. All p-values refer to multivariate model logistic analysis data

Biphasic insulin aspart 30 and insulin glargine administered with oral anti-diabetic drugs in type 2 diabetes mellitus: a systematic review and meta-analysis

A. Schubert¹, M. Ziola², S. Siejka², P. Rys², I. Skrzekowska-Baran¹, M.T. Malecki³;

¹Novo Nordisk Pharma Sp. z o.o., Warsaw, Poland, ²HTA Consulting,

Krakow, Poland, ³Department of Metabolic Diseases, Jagiellonian University, Krakow, Poland.

Background and aims: There is an on-going debate whether the addition of biphasic insulin analog to oral anti-diabetic drugs (OADs) provides any clinical advantages over basal insulin added to OADs in patients with type 2 diabetes mellitus (T2DM). A systematic review-based study was performed to compare the clinical outcomes of treatment with biphasic insulin aspart 30 (BIAsp 30) and insulin glargine (IGlar) in T2DM patients inadequately controlled with OADs.

Materials and methods: The analysis was based on randomized controlled trials (RCTs) identified by a systematic literature search in medical databases (MEDLINE, EMBASE, The Cochrane Library and others) up to February 2011. Studies met the inclusion criteria if they compared BIAsp 30 vs. IGlar added to at least one OAD in T2DM patients. It should be noted that in some studies, patients in the BIAsp 30 group received different OADs than those from the IGlar group. Results were presented as the weighted mean difference (WMD) or odds ratio (OR) with a 95% confidence interval.

Results: We identified 6 trials including together 1422 patients followed from 24 to 28 weeks. A meta-analysis of these 6 RCTs demonstrated that BIAsp 30 reduced HbA_{1c} level more effectively than IGlar (WMD = -0.23 % [-0.40, -0.05]). In addition, statistically significant differences were observed in favour of BIAsp 30 for mean prandial glucose increment (3 RCTs; WMD = -14.70 mg/dl [-20.09, -9.31]); but not for fasting plasma glucose (4 RCTs; WMD = 6.83 mg/dl [-12.76, 26.43]). Pooled data of 4 RCTs showed that the percentage of patients with at least one hypoglycaemic episode was higher in the BIAsp 30 group than in the IGlar group (61% vs. 50%; OR = 1.59 [1.22, 2.07]). However, no significant differences were revealed in respect to severe hypoglycaemic episodes (6 RCTs; 1% vs. 1%; OR = 0.84 [0.33, 2.15]) and premature discontinuation (5 RCTs; 12% vs 11%; OR = 1.23 [0.68, 2.25]). There was no difference in weight gain between the groups (5 RCTs; WMD = 0.41 kg [-1.16, 1.98]).

Conclusion: When compared to IGlar, BIAsp 30 added to OAD treatment resulted in better glycaemic control in T2DM patients and did not increase risk of severe hypoglycaemia.

Insulin detemir versus insulin glargine for type 2 diabetes mellitus

A.C.R. Simon, S.G. Swinnen, F. Holleman, J.B.L. Hoekstra, J.H. DeVries; Internal medicine, Academic Medical Center, Amsterdam, Netherlands.

Background and aims: Chronically elevated blood glucose levels are associated with significant morbidity and mortality. Many diabetes patients will eventually require insulin treatment to maintain good glycaemic control. There are still uncertainties about the optimal insulin treatment regimens for type 2 diabetes, but the long-acting insulin analogues seem beneficial. Several reviews have compared either insulin detemir or insulin glargine to NPH insulin, but research directly comparing both insulin analogues is limited. The aim of the study is to assess the effects of insulin detemir and insulin glargine compared with each other in the treatment of type 2 diabetes mellitus.

Materials and methods: We searched MEDLINE, EMBASE, The Cochrane Library, online registries of ongoing trials and abstract books. All randomised controlled trials (RCTs) comparing insulin detemir with insulin glargine with a duration of 12 weeks or longer were included.

Results: This review examined 4 trials lasting 24 to 52 weeks involving 2250 people randomized to either insulin detemir or glargine. Insulin glargine was dosed once-daily in the evening. Insulin detemir was initiated once-daily in the evening with the option of an additional dose in the morning in three studies and initiated twice-daily in one study. 13.6 to 57.2% of patients were

injecting insulin detemir twice-daily at end of trial. Glycaemic control, measured by glycosylated haemoglobin A1c (HbA_{1c}), FPG (fasting plasma glucose) and HbA_{1c} ≤ 7% with/without hypoglycaemia, did not differ significantly between treatment groups, except for one outcome measure; insulin glargine was associated with lower FPG at study endpoint. The results showed no differences in overall, nocturnal and severe hypoglycaemia between treatment groups. Insulin detemir was associated with less weight gain. Treatment with insulin glargine resulted in a lower daily basal insulin dose and a lower number of injection site reactions. There was no difference in the variability of FPG or glucose values in 24-hour profiles between treatment groups. It was not possible to draw conclusions on quality of life, costs or mortality.

Conclusion: Our analyses suggest that there is no clinically relevant difference in efficacy or safety between insulin detemir and insulin glargine for targeting hyperglycaemia. However, to achieve the same glycaemic control insulin detemir was often injected twice-daily in a higher dose but with less weight gain, while insulin glargine was injected once-daily, with somewhat fewer injection site reactions.

1035

Basal-bolus therapy with insulin degludec improves long-term glycaemic control with fewer nocturnal hypoglycaemic events compared with insulin glargine in people with type 2 diabetes

P.A. Hollander¹, A.B. King², A.O. Francisco³, L. Endahl³, A. Garber⁴

¹Baylor Endocrine Center, Baylor University Medical Center, Dallas, USA,

²Diabetes Care Center, Salinas, USA, ³Novo Nordisk A/S, Søborg, Denmark,

⁴Baylor College of Medicine, Houston, USA.

Background and aims: Upon subcutaneous injection, insulin degludec (IDeg), a new-generation basal insulin, forms soluble multi-hexamers which dissociate slowly to produce an ultra-long and flat action profile. This 1-year, open-label, treat-to-target trial compared the efficacy and safety of IDeg with insulin glargine (IGlar), both administered once daily with mealtime insulin aspart (IAsp) ± metformin ± pioglitazone as part of a basal-bolus treatment regimen.

Materials and methods: 992 subjects (mean: age 58.9 years; diabetes duration 13.5 years; HbA_{1c} 8.3%; FPG 9.2 mmol/l) with type 2 diabetes and HbA_{1c} 7–10% after ≥ 3 months of any insulin regimen ± OAD(s), randomised (3:1) to IDeg or IGlar were analysed. Basal and bolus insulin were titrated weekly throughout the study using structured algorithms. The target glucose for basal insulin was an FPG < 5 mmol/l.

Results: A similar proportion of subjects completed the trial with IDeg (83%) and IGlar (85%). At the end of the study, IDeg and IGlar improved overall HbA_{1c} levels by 1.2 %-points and 1.3 %-points, respectively (estimated treatment difference (ETD) IDeg–IGlar: 0.08 %-points [95% CI: –0.05, 0.21]), and half of the subjects in both groups achieved HbA_{1c} < 7% (p=NS). FPG was reduced by 2.4 mmol/l with IDeg and by 2.1 mmol/l with IGlar (ETD: –0.29 mmol/l [95% CI: –0.65; 0.06], p=NS). The rates of overall confirmed hypoglycaemia (defined as episodes with PG < 3.1 mmol/l or considered severe according to ADA definition) were significantly lower with IDeg than IGlar (11.1 vs. 13.6 episodes/patient-year; estimated rate ratio (ERR) IDeg/IGlar: 0.82 [95% CI: 0.69; 0.99], p=0.0359). Similarly, the rate of nocturnal confirmed hypoglycaemia, (confirmed hypoglycaemia occurring between 00:01–05:59) was 25% lower in the IDeg group compared with the IGlar group (1.4 vs. 1.8 episodes/patient-year; ERR: 0.75 [95% CI: 0.58; 0.99] p=0.0399). IDeg was well tolerated; the rates of adverse events were similar between groups and there were no treatment-specific patterns. By the end of the study, total mean daily insulin doses were 1.46 U/kg and 1.42 U/kg in the IDeg and IGlar groups, respectively. In both groups, the relative contribution of the basal and bolus components was approximately 50:50.

Conclusion: Insulin degludec, given as basal-bolus treatment with insulin aspart in people with type 2 diabetes, improves long-term glycaemic control with a significantly lower risk of overall and nocturnal hypoglycaemia compared with insulin glargine.

Comparison of 3 intensified insulin regimens added to oral therapy for type 2 diabetes: twice-daily aspart premixed vs glargine plus 1 prandial glulisine or stepwise addition of glulisine to glargine

M.C. Riddle¹, A. Vlahovic², B. Jones³, J. Rosenstock⁴

¹Oregon Health & Science University, Portland, ²sanofi-aventis US,

Bridgewater, ³Smith Hanley Consulting Group, Lake Mary, ⁴Dallas Diabetes and Endocrine Center, Dallas, USA.

Background and aims: How to advance from unsuccessful oral antidiabetic therapy to intensified insulin therapy in type 2 diabetes is debated.

Materials and methods: A 60-week randomized, open-label study compared efficacy, hypoglycemia, and body-weight after adding BID premixed 70/30 protamine-aspart/aspart (PREMIX, n=192), glargine + 1 prandial glulisine dose (GLARG+1, n=189), or glargine plus stepwise glulisine (GLARG+0-3, n=191).

Results: Mean baseline HbA_{1c} was 9.4% after a 4-week run-in on 2-3 oral agents; age 54 years, diabetes duration 9 years, BMI 33.2 kg/m². Insulin was titrated seeking fasting and preprandial glucose < 100 mg/dL (5.6 mmol/L) with HbA_{1c} < 6.5%. Each regimen reduced HbA_{1c} (Figure) but more randomized patients had week 60 HbA_{1c} < 7% with GLARG+1 (49%, P<0.025) or GLARG+0-3 (45%, P<0.05) than with PREMIX (39%), and more did so without hypoglycemia with GLARG+1 (24%, P<0.05) or GLARG+0-3 (24%, P<0.01) than with PREMIX (14%). Mean ΔHbA_{1c} at endpoint (last observation carried forward [LOCF]) was –1.8±0.1% with PREMIX vs –2.1±0.1% (P=0.06) and –2.2±0.1% (P<0.01) with GLARG+1 and GLARG+0-3. Adjusted event-rates per patient-yr (ER) and incidences (%) for categories of hypoglycemia are reported below. Δ in body weight at week 60 was similar among regimens.

Conclusion: Significantly larger proportions of patients achieved target HbA_{1c} < 7% on both glargine-based regimens with less hypoglycemia than with premixed insulin.

	PREMIX		GLARG+1		GLARG+0-3

Randomised open-label trial of insulin lispro protamin suspension versus insulin glargine once daily in basal-bolus therapies with insulin lispro in type 2 diabetes patients

D. Giugliano¹, S. Cleall², A.E. Pontiroli³, V. Koivisto⁴

¹Division of Metabolic Diseases, Policlinico Seconda Università di Napoli,

Italy, ²Eli Lilly and Company, Windlesham, Surrey, UK, ³Dipartimento di

Medicina, Chirurgia e Odontoiatria, Università degli Studi di Milano, Italy,

⁴Eli Lilly and Company, Frankfurt, Germany.

Background and aims: This study compares the efficacy and safety of insulin lispro protamine suspension (ILPS) versus insulin glargine once daily in a basal-bolus regimen in patients with type 2 diabetes mellitus (T2DM) who no longer achieved glycemic control with combination treatment consisting of insulin and oral antidiabetic medication (OAM).

Materials and methods: In this 24-week, open-label, parallel group study, adult insulin-pretreated T2DM patients were randomized to receive a basal-bolus regimen of once daily ILPS or insulin glargine, plus insulin lispro before main meals 2 to 3 times a day. Main inclusion criteria were OAM treatment, HbA_{1c} 7.5% to 11.0%, BMI 25 to 45 kg/m². All OAMs except metformin were discontinued at randomization. Insulin doses were titrated to predefined blood glucose (BG) targets over 12 weeks. Non-inferiority of ILPS versus glargine was assessed by comparing the upper limit of the 95% confidence interval (CI) for the change of HbA_{1c} from baseline to Week 24 (adjusted for country and baseline HbA_{1c}) with a non-inferiority margin of 0.4%. Non-inferiority was assessed on the per-protocol population; other analyses were performed on the full analysis set. Secondary efficacy and safety variables included HbA_{1c} categories, BG profiles, insulin doses, hypoglycemic episodes, adverse events, and vital signs.

Results: 383 patients were randomized (age 33–86 years; 43% male) to receive ILPS (n=192) or insulin glargine (n=191). Non-inferiority of ILPS versus glargine in the change of HbA_{1c} from baseline to 24 weeks was shown (Table). HbA_{1c} targets of <7.0% were achieved by 21.7% (ILPS) versus 29.4% (glargine) of patients. No clinically relevant differences between treatments were observed in self-monitored BG profiles at 24 weeks. Mean basal/meal-time insulin doses at Week 24 were 29.6/36.2 IU/day (ILPS) versus 32.8/42.2 IU/day (glargine); the difference was not statistically significant for total dose at Week 24 (p=0.7). 56.1% (ILPS) versus 63.6% (glargine) of patients experienced any hypoglycemia (p=0.2), 25.7% (ILPS) versus 19.3% (glargine) experienced nocturnal hypoglycemia (p=0.2). No clinically relevant differences were noted in any other variables.

Conclusion: A basal-bolus regimen with ILPS once daily resulted in non-inferior glycemic control compared to a similar regimen with glargine, without statistically significant or clinically relevant differences in hypoglycemia. ILPS-based regimens can be considered an alternative to basal-bolus regimens with glargine for T2DM patients.

Change in HbA_{1c} from Baseline to Week 24 - Analysis of Covariance

	ILPS				Glargine				Difference ILPS minus Glargine

Efficacy and safety of a fixed dose combination of glimepiride and metformin versus glimepiride when added in to insulin glargine in patients with type 2 diabetes

J.-M. Lee¹, J.-H. Lee¹, S.-H. Park¹, S.-J. Kim², K.-Y. Park³, D.-M. Lim³, S.-W. Chun², J.-M. Lee⁴, K.-S. Park¹;

¹Endocrinology & Metabolism, Department of Internal Medicine, Eulji University Hospital, Daejeon, Republic of Korea, ²Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea, ³Konyang University Hospital, Daejeon, Republic of Korea, ⁴The Catholic University of Korea, Daejeon ST.Mary's Hospital, Daejeon, Republic of Korea.

Background and aims: Patients (pts) with type 2 diabetes mellitus (T2D) with non-controlled blood glucose level are recommended to be treated and initiated with aggressive oral combination therapy and early insulin therapy. The aim of this study was to evaluate if a fixed dose combination of glimepiride 1mg and metformin 500mg twice daily (GMet) is noninferior to glimepiride 4mg (G) once daily in change in HbA_{1c} when added to insulin glargine in adults with suboptimally controlled T2D.

Materials and methods: This open-label, multicenter, randomised, 16-week trial enrolled pts with T2D (BMI ≥ 21 kg/m² and ≤ 11 kg/m², HbA_{1c} > 7.0% and < 11% who had been treated ≥ 3 months with glimepiride and metformin. Pts were randomly assigned to receive either GMet (n=49) or G (n=48). Statistical analysis was performed based on intent-to-treat population using last observation carried forward method. The effectiveness of GMet (vs G) was assessed

hierarchically by a non-inferiority comparison, with a margin of 0.4%, and then by a superiority comparison.

Results: A total of 97 patients were randomized. Baseline demographics were similar across treatment groups. At 26-week endpoint, least squares mean difference in HbA_{1c} change between groups (GMet minus G) was -0.76% (95% CI: -1.10 to -0.42) demonstrating superiority of GMet to G, adjusted mean HbA_{1c} changes from baseline were -0.97% (-0.99 ± 0.94) and -0.22% (-0.20 ± 1.02) (Mean ± SD) in glimepiride/metformin and glimepiride groups, respectively; between-treatment difference -0.76% (95% CI -1.1 to -0.42; p<0.0001), showing statistical significance. Adjusted mean fasting plasma glucose level changes were -51.2mg/dl (-53.3 ± 53.9) and -39.8mg/dl (-37.6 ± 43.9) (Mean ± SD) from baseline, and the difference between two groups was -11.3mg/dl (95% CI -28.0 to 5.4; p=0.1807). 2 hr post prandial glucose levels changed by average -69.7 (-70.68 ± 88.8) for glimepiride/metformin group and -37.8 (-36.9 ± 86.6) mg/dl for glimepiride group with statistical difference of -31.9mg/dl (95% CI -61.6 to -2.3; p=0.0349). Differences of both HOMA-IR and β-cell changes between two groups were statistically non-significant (p=0.7409, 0.4835). The glimepiride/metformin group required lesser insulin amount than the glimepiride group (6.6 ± 9.9 and 12.5 ± 13.9 IU) (p=0.0204). Hypoglycemic events were experienced in 19 patients (39.6%) in glimepiride/metformin group and 20 patients (41.7%) in glimepiride group, and night time hypoglycemic events were experienced in 9 patients (18.8%) in both groups, but without any serious hypoglycemic adverse events.

Conclusion: In patients with type 2 diabetes poorly controlled on oral anti-diabetic therapy, insulin plus low-dose, fixed-combination therapy (glimepiride 1mg and metformin 500mg) or glimepiride 4mg therapy was effective in improving glycemic control, and both were well tolerated. The group with glimepiride/metformin was more effective in reducing HbA_{1c} and controlling after-meal hyperglycemic levels and this group required lesser insulin demand, without increasing hypoglycemic incidence.

Study of once-daily Levemir (SOLVE™) 3: safety of once-daily insulin detemir in patients with type 2 diabetes treated with oral antidiabetic therapy

S.A. Ross¹, G. Dzida², R.J. Ligthelm³, on behalf of the SOLVE Study Group;

¹Department of Medicine, University of Calgary, Canada, ²Department of Internal Diseases, Medical University of Lublin, Poland, ³EHM Clinic, Hoofddorp, Netherlands.

Background and aims: Concerns over the risks of hypoglycaemia, particularly major hypoglycaemia, remain an important barrier to diabetes treatment intensification and insulin initiation. The primary objective of the SOLVE study was to evaluate the incidence of serious adverse drug reactions, including major hypoglycaemic events during 24-weeks of treatment with once-daily insulin detemir in insulin naive patients with T2DM treated with one or more oral antidiabetic (OAD) drugs.

Materials and methods: This international cohort study was conducted in 10 countries. Data was collected at 3 routinely-scheduled clinic visits (baseline, 12-week, and 24-week visit). Hypoglycaemia episodes were defined as follows: major hypoglycaemia - event requiring third party assistance, minor hypoglycaemia - a daytime or nocturnal glucose measurement < 3.1 mmol/L +/- symptoms, and nocturnal hypoglycaemia - any minor episode occurring between bedtime and rising the next morning. Major hypoglycaemia was recorded as events recalled within the preceding 12 weeks (4 weeks in the UK), and minor hypoglycaemia as events recalled within the preceding 4 weeks (all countries).

Results: A total of 14,785 participants have been enrolled in the study. Of these, 10,786 participants have completed the 24 week study. Reasons for study withdrawal included loss to follow-up (n=17), discontinuation of OAD (n=20) or trial drug (n=38), incorrect trial drug regimen (n=50), addition of short acting insulin (n=81), adverse drug reaction (n=3) and other unspecified reasons (n=80). Participants included in the safety analysis were 53% male, age 62 ± 11 years, BMI 29.6 ± 5.3, and duration of diabetes of 10 ± 7 years, with a pre-insulin HbA_{1c} of 9.0 ± 1.6%. By the end of study, the HbA_{1c} had decreased to 7.7 ± 1.2%. The number of subjects experiencing major hypoglycaemia and/or a serious adverse drug reaction was n=21 (0.2%): comprising 15 patients with at least one episode of hypoglycaemia. The number of participants with any major hypoglycaemic event decreased from 44 (0.4%) pre-insulin to 11 (0.1%) by end of study (0.03 to <0.01 events per person year - see figure). The proportion with at least one episode of

minor hypoglycaemia increased from 3.6% pre-insulin to 6.2% by end of study (1.36 to 1.79 events per person year - see figure). The proportion with at least one episode of nocturnal hypoglycaemia also increased from 0.8% pre-insulin to 1.3% by end of study (0.20 to 0.28 events per person year).

Conclusion: The addition of once-daily insulin detemir to existing OAD regimens was safe and effective, and the severe adverse drug reactions were rare. The rates of hypoglycaemia, particularly major hypoglycaemia, were low despite clinically relevant reductions in HbA_{1c}. The distribution of hypoglycaemia with respect to OAD use are being analysed and will be presented at the meeting.

Pointe-à-Pitre, France, ⁸Novo Nordisk A/S, Søborg, Denmark, ⁹Department of Medicine, Kuopio University Hospital, Finland.

Background and aims: Insulin degludec (IDeg) is a new-generation basal insulin that forms soluble multi-hexamers upon subcutaneous (s.c.) injection, resulting in an ultra-long and flat action profile. Insulin degludec/insulin aspart (IDegAsp) is a soluble co-formulation of IDeg (70%) and insulin aspart (IAsp, 30%) designed to provide mealtime and basal insulin coverage. In this phase 2, 16-week, open-label, treat-to-target trial, the safety and efficacy of IDegAsp were evaluated in insulin-naïve people with type 2 diabetes inadequately controlled on oral anti-diabetic drugs.

Materials and methods: Participants (mean: 60 years old; HbA_{1c} 8.5%; FPG 11.6 mmol/l; BMI 31.4 kg/m²) were randomised to twice-daily IDegAsp (n=61), BIAsp 30 (n=62) or an alternative formulation of IDegAsp (development discontinued, results not shown; n=59), all in combination with metformin (1500 or 2000 mg/day). Insulin was injected s.c. before both breakfast and the evening meal and titrated to a pre-breakfast and pre-dinner PG target of 4.0–6.0 mmol/l.

Results: Mean HbA_{1c} after 16 weeks (primary endpoint) was comparable for IDegAsp (6.7%) and BIAsp 30 (6.7%) (estimated treatment difference [ETD] IDegAsp-BIAsp 30 = -0.02% [-0.27; 0.24]). With IDegAsp, more subjects achieved HbA_{1c} <7.0% without confirmed hypoglycaemia (PG <3.1 mmol/l) in the last 4 weeks of treatment compared with BIAsp 30 (67% vs. 40% of subjects). Mean FPG at Week 16 was significantly lower for IDegAsp than BIAsp 30 (6.4 vs. 7.5 mmol/l; ETD: -0.99 mmol/l [-1.68; -0.29]). No severe hypoglycaemia was reported. The rate of confirmed hypoglycaemia was 58% lower for IDegAsp than BIAsp 30 (2.9 vs. 7.3 episodes/patient-year; estimated rate ratio: 0.42 [0.23; 0.75]). Nocturnal confirmed hypoglycaemia was less frequent for IDegAsp (7 episodes) than BIAsp 30 (20 episodes). The overall rate of adverse events was similar between insulins, the majority (>99%) were

mild or moderate in severity, and there was no treatment-specific pattern or clustering.

Conclusion: In this proof-of-concept trial IDegAsp was safe, well tolerated and provided comparable overall glycaemic control to BIAsp 30. IDegAsp was associated with a significantly lower FPG and a significantly lower rate of confirmed hypoglycaemia than BIAsp 30.

Insulin degludec in a flexible daily dosing regimen provides similar glycaemic control without increasing rates of hypoglycaemia compared to dosing the same time daily in type 2 diabetes

K.I. Birkeland^{1,2}, I. Raz^{3,4}, S. Gough⁵, S.L. Atkin⁶, M.V. Shestakova⁷, L. Blonde⁸, L. Meneghini⁹, K. Begtrup¹⁰, T. Johansen¹⁰, S.C. Bain¹¹,

A/S, Søborg, Denmark, ¹¹Abertawe Bro Morgannwg University Health

Board, Singleton Hospital, Swansea, UK.

Background and aims: Current basal insulin preparations should be injected at a consistent time to ensure optimal biologic action. Patients have difficulty adhering to strict dosing schedules for many reasons. Insulin degludec (IDeg), which forms soluble multi-hexamers upon s.c. injection resulting in an ultra-long and consistent action profile, may enable more flexible dosing intervals as an alternative to the recommended strict dose timing of currently available insulins. In this registration trial for IDeg, we investigated whether once-daily administration of IDeg in a flexible dosing regimen (IDeg Flex) provides comparable glycaemic control as administration at the same time daily with the evening meal (IDeg OD).

Materials and methods: In this 26-week, open-label, treat-to-target trial, people with type 2 diabetes were randomised to IDeg Flex (n=229) and required to alternate the timing of insulin administration to morning and evening, in effect creating 8–40 h intervals between insulin doses, or to IDeg OD (n=228), where injections were given daily with the evening meal. Insulin was added to existing OAD therapy (if any) and titrated to FPG <5 mmol/l (90 mg/dl). Mean baseline characteristics such as age (56.2 vs. 56.5 yrs), HbA_{1c} (8.5 vs. 8.4%), diabetes duration (10.8 vs. 10.3 yrs) and BMI (29.3 vs. 29.4 kg/m²) were comparable between the IDeg Flex and IDeg OD groups, respectively.

Results: At 26 weeks, IDeg Flex and IDeg OD improved HbA_{1c} by 1.3 and 1.1 %-points, respectively (estimated treatment difference (ETD) IDeg Flex-IDeg OD: -0.13 %-points [95% CI: -0.29; 0.03]). Mean FPG was reduced from 9.0 to 5.8 mmol/l (IDeg Flex) and from 8.8 to 5.8 mmol/l (IDeg OD) (ETD: -0.05 mmol/l [-0.45; 0.35]). At Week 26, groups were similar in terms of fluctuations in 9-point self-measured plasma glucose (SMPG) (estimated treatment ratio (ETR) IDeg Flex/IDeg OD: 0.94 [0.86; 1.04]) and variation in pre-breakfast SMPG (ETR: 1.04 [0.94; 1.14]). Rates of confirmed hypoglycaemia (PG <3.1 mmol/l (56 mg/dl) or severe) were 3.6 episodes/patient-yr in both groups (estimated rate ratio (ERR) IDeg Flex/IDeg OD: 1.10 [0.79; 1.52]); the rate of nocturnal confirmed hypoglycaemia was 0.6 episodes/patient-yr in both groups (ERR: 1.18 [0.66; 2.12]). Severe hypoglycaemia was rare (2 episodes/group).

Conclusion: By using extreme dosing intervals of between 8 and 40 hours, the trial demonstrates that IDeg can be dosed flexibly at any time of the day and that changes in the injection time from day to day do not affect glycaemic control or risk of hypoglycaemia. The flexible dosing regimen made possible by IDeg will facilitate the integration of insulin therapy with daily activities and potentially improve adherence and acceptance of treatment.

Differences in glycaemic reductions between insulin therapies according to body mass index: pooled results from multinational clinical trialsE. Wang¹, J. Lin², M.-P. Dain³, G. Dailey⁴¹sanofi-aventis, Bridgewater, USA, ²Novosys Health, Flemington, USA,³sanofi-aventis, Paris, France, ⁴Scripps Clinic and Research Foundation Division of Diabetes and Endocrinology, La Jolla, USA.

Background and aims: Insulin glulisine is an analog of human insulin designed for use as a rapid-acting insulin. This study used pooled data from 2 previously reported trials to compare the efficacy of twice daily glulisine with twice daily regular human insulin (RHI) in obese and non-obese patients. Patients had >6 months of continuous insulin therapy prior to study entry. HbA_{1c} results of the 2 studies showed noninferiority of glulisine to RHI ($P = 0.573$) and a small difference in favor of glulisine ($P = 0.003$), respectively.

Materials and methods: In the parent studies, 1666 patients with type 2 diabetes (mean HbA_{1c} 7.6%) were randomised and treated with glulisine + NPH ($n = 833$) or RHI + NPH ($n = 833$) for up to 26 weeks. Subjects were allowed to continue on the same dose of pre-study regimens of oral antidiabetic drug therapy (unless hypoglycaemia necessitated a dose change). Data for both trials were pooled then compared in patients with body mass index (BMI) \geq and < 30 kg/m². Additional analysis tested the impact of factors on change in HbA_{1c} from baseline to Month 6 using multivariable generalized linear model regression. Independent covariates included insulin type, age, gender, BMI, and baseline HbA_{1c}.

Results: This pooled analysis included 1666 patients with a mean (SD) age of 59.0 ± 9.7 years. 587 (35.2%) patients had a BMI < 30 (mean 26.9 ± 2.3 kg/m²) and 1079 (64.8%) had a BMI ≥ 30 (mean 36.1 ± 5.2). Female patients made up 40.2% and 42.2% of the glulisine + NPH and RHI + NPH groups, respectively, in the BMI < 30 cohort. In the BMI ≥ 30 cohort, 51.5% and 53.7% were female, respectively. Baseline HbA_{1c} was similar in the overall glulisine + NPH and RHI + NPH groups: 7.6 ± 0.9 % and 7.5 ± 0.9 %, respectively. Initiating with glulisine + NPH was associated with a greater reduction in HbA_{1c} than initiating with RHI + NPH in obese patients (glulisine + NPH: Δ HbA_{1c} = -0.45%; RHI + NPH: Δ HbA_{1c} = -0.33%, $P = 0.0219$). Reductions in HbA_{1c} among patients with BMI < 30 kg/m² were similar for glulisine + NPH (-0.28%) and RHI + NPH (-0.25%; $P = 0.7$). Other factors associated with significant reductions in HbA_{1c} in the overall pooled analysis included BMI ($P = 0.02$), age ($P < 0.001$), insulin treatment ($P = 0.04$) and baseline HbA_{1c} ($P < 0.001$) (Table). Serious hypoglycaemic episodes were experienced by 2.4% and 2.3% of glulisine + RHI patients, respectively, with BMI ≥ 30 ($P = 0.932$); and by 2.5% and 3.6% of glulisine + RHI patients, respectively with BMI < 30 ($P = 0.439$).

Conclusion: These results suggest that glulisine + NPH treatment in obese patients may result in greater HbA_{1c} reductions than RHI + NPH with comparable risk of hypoglycaemia. Other factors that were significantly associated with greater HbA_{1c} reduction in this analysis were older age, higher BMI and higher baseline HbA_{1c}.

Factors That Impacted Reduction of HbA_{1c}

Parameters	Impact on HbA _{1c} Reduction ^a	Confidence Interval	P-value

PS 092 Insulin therapy in type 1 diabetes

1043

Accelerated absorption and reduced glycaemic variability in type 1 diabetes mellitus patients by human hyaluronidase-facilitated coinfusion of a prandial insulin analogueM. Hompesch¹, D.B. Muchmore², L. Morrow¹, D.E. Vaughn²¹Profil Institute for Clinical Research, Chula Vista, ²Halozyne Therapeutics, Inc., San Diego, USA.

Background and aims: To compare the pharmacokinetic (PK) and glucodynamic responses to insulin aspart delivered \pm human hyaluronidase by insulin pump for 72 hours in patients with type 1 diabetes mellitus (T1DM).

Materials and methods: An insulin aspart formulation (Aspart-PH20) with human hyaluronidase (rHuPH20) was compared to the commercial insulin aspart formulation (NovoLog[®]) for three days of diabetes treatment when delivered by continuous subcutaneous infusion in an inpatient setting. Data are available for 13 [9 male, 4 female; mean age $39.7 (\pm 9.7)$; mean BMI $26.2 (\pm 3.4)$] of planned 18 T1DM patients who regularly use insulin pumps. A euglycemic clamp experiment with a 0.15 U/kg bolus was conducted approximately $\frac{1}{2}$ day after infusion initiation; usual individual basal rate was continued during clamps and PK results are thus baseline-subtracted. Patients also received standardized solid evening meals (45-50% CHO, 18-22% protein, 30-34% fat) on each of three consecutive days and postprandial glycemic responses were measured by YSI.

Results: Aspart-PH20 was more rapidly absorbed than the commercial formulation leading to greater early exposure and action and reduced late exposure and action. Similar total exposure (63 ± 13 v. 55 ± 9 nM*min; 114%, $p = .096$) was shifted to earlier times post bolus infusion with a time to 50% exposure reduced from 119 ± 22 to 85 ± 20 minutes with rHuPH20 ($p = .0005$), resulting in 64% more insulin exposure in the 1st hour ($p < .0001$) and 58% less in beyond 4 hours ($p = .006$). Comparable insulin action, total glucose infused, (31.8 ± 13.5 v. 31.7 ± 11.0 mg/kg) was also accelerated with time to 50% glucose infused reduced from 154 ± 19 to 133 ± 19 minutes ($p = .007$), 20% more action in the first 2 hours ($p = .047$) and 37% less beyond 4 hours ($p = .008$). The accelerated insulin absorption and action led to reduced postprandial hyperglycemic excursion. The average two hour PPG for three consecutive dinners was reduced from 148 ± 34 to 118 ± 28 mg/dL for the formulation with rHuPH20 ($p = .009$) and total hyperglycaemic excursions ($AUC_{0-3hr} > 140$ mg/dL) was reduced 44% ($p = .02$). There were no significant differences in hypoglycemic risk, and the minimum PPG were similar with (83 ± 17) and without (88 ± 19 mg/dL) rHuPH20; $p = .46$. Both test articles were well tolerated.

Conclusion: Aspart-PH20 was absorbed more rapidly compared to the commercial aspart formulation, and this accelerated insulin exposure and action profile translated into superior control of postprandial blood glucose in patients with T1DM.

Clinical Trial Registration Number: NCT01275131

1044

Impact of the dawn phenomenon and the get-up phenomenon on insulin therapyG. Freckmann¹, A. Baumstark¹, S. Pleus¹, C. Haug¹, L.G. Krinkel², A. Buhr²¹Institute for Diabetes-Technology GmbH at the University of Ulm, Germany, ²Roche Diabetes Care AG, Burgdorf, Switzerland.

Background and aims: Many people with type 1 diabetes experience increased fasting blood glucose (BG) values after getting up. This increase is often caused by the dawn phenomenon but it may also be caused by another effect, the get-up phenomenon. During a study with closed-loop control we

observed the get-up phenomenon and compared it to the dawn phenomenon to analyze how this phenomenon should be considered in subcutaneous insulin infusion therapy.

Material and methods: 24 subjects with type 1 diabetes on continuous subcutaneous insulin infusion were enrolled for a study with overnight closed-loop control and visited the study site on three occasions. Each visit lasted three days. Blood sampling was performed once per hour between midnight and 06:00 A.M. and every 10 min after 06:30 A.M. The evaluation of the get-up phenomenon was performed on these BG values. Subjects were woken at 05:45 A.M. and had to get up until 06:00 A.M. The analysis was performed on all data gathered. A subgroup of patients who had at least three successful experiments was evaluated separately. An experiment was successful if there were no unusually high insulin delivery rates (more than 1.6 times the patient's basal rate), no hypo- or hyperglycemia interventions and no missing BG values and if no hourly basal rate was zero. We compared the BG difference before get-up (between 04:00 A.M. and 05:00 A.M. and between 05:00 A.M. and 06:00 A.M.) and after get-up (between 06:00 A.M. and 06:40 A.M.). **Results:** Results are given in the table.

Conclusion: The get-up phenomenon seemed to be more pronounced than the dawn phenomenon. Some patients may experience a significant BG increase after get-up. This phenomenon may be antagonized by increasing the basal rate in the morning or, if patients get up at different times of day, an additional bolus delivery. Further investigation is required to quantify the get-up phenomenon and to obtain information about patient groups most likely to be affected by this phenomenon.

BG difference in mg/dl/h (Mean \pm SD; [Range]) between:	All experiments (24 subjects, 140 nights)	Successful experiments (16 subjects, 70 nights)
- 04:00 A.M. and 05:00 A.M.	10.3 \pm 9.6; [-38.0 - 86.1]	6.6 \pm 6.5; [-15.5 - 30.0]
- 05:00 A.M. and 06:00 A.M.	8.1 \pm 10.3; [-29.2 - 65.0]	10.5 \pm 9.4; [-15.2 - 65.0]
- 06:00 A.M. and 06:40 A.M.	20.8 \pm 12.3 (*); [-38.6 - 84.0]	31.4 \pm 14.5 (*); [-15.0 - 84.0]

BG changes from 04:00 A.M. to 06:40 A.M. for all experiments and for successful experiments. The increase in BG after get-up is significantly larger than prior to get-up. (*) $p < 0.001$

Basal-bolus therapy with insulin degludec improves long-term glycaemic control with less nocturnal hypoglycaemia compared with insulin glargine in type 1 diabetes: results of a 1-year trial

D.L. Russell-Jones^{1,2}, A.O. Francisco³, H. Pei⁴, S.R. Heller⁵;

¹Diabetes and Endocrinology, Royal Surrey County Hospital, Guildford, UK,

²University of Surrey, Guildford, UK, ³Novo Nordisk A/S, Søborg, Denmark,

⁴Novo Nordisk Inc, Princeton, USA, ⁵School of Medicine and Biosciences, University of Sheffield, UK.

Background and aims: This 1-year, open-label, treat-to-target trial compared the efficacy and safety of insulin degludec (IDeg), a new-generation basal insulin with an ultra-long and flat action profile, with insulin glargine (IGlar), both administered once-daily in combination with mealtime insulin aspart in basal-bolus therapy for type 1 diabetes management.

Materials and methods: The trial comprised 629 adults with type 1 diabetes who had previously been treated with any basal-bolus insulin therapy for at least 1 year (mean: age 43.0 years; diabetes duration 18.9 years; HbA_{1c} 7.7%). Participants were randomised in a 3:1 ratio to receive either IDeg or IGlar, respectively, and the basal insulin was titrated aiming to meet an FPG target <5 mmol/l.

Results: A similar proportion of participants completed the trial in the IDeg (86%) and IGlar (87%) groups. By the end of the trial, overall glycaemic control improved by 0.4 %-points with both IDeg and IGlar (estimated treatment difference (ETD) IDeg-IGlar: -0.01 %-points [95% CI: -0.14; 0.11]); the proportion of participants who achieved a target HbA_{1c} <7% was also comparable between the IDeg and IGlar groups (40% vs. 43%, respectively, $p = \text{NS}$). The observed reductions in mean FPG after 1 year, 1.27 mmol/l with IDeg and 1.39 mmol/l with IGlar, were similar (ETD: -0.33 mmol/l [95% CI: -1.03; 0.36] $p = \text{NS}$). The time taken to reach the titration target was significantly shorter in the IDeg group, compared with the IGlar group (median of 5 vs. 10 weeks, estimated hazard ratio: 1.37 [95% CI: 1.12; 1.67] $p = 0.002$). At the end of the study, mean daily total insulin doses were 0.75 U/kg and 0.82 U/kg for the IDeg and IGlar groups respectively, divided ~50:50 between the basal and bolus components for both groups. Rates of overall confirmed hypoglycaemia (PG < 3.1 mmol/l or severe episodes as per ADA definition) were comparable between IDeg and IGlar (42.5 vs. 40.2 episodes/patient-year; estimated rate

ratio (ERR) IDeg /IGlar: 1.07 [95% CI: 0.89; 1.28], $p = \text{NS}$). However, the rates of nocturnal confirmed hypoglycaemia were 25% lower with IDeg (4.4 vs. 5.9 episodes/patient-year; ERR: 0.75 [95% CI: 0.59; 0.96] $p = 0.021$). Overall rates of adverse events were similar between IDeg and IGlar, with no treatment-specific pattern or clustering.

Conclusion: Insulin degludec, given as basal-bolus treatment with insulin aspart in people with type 1 diabetes, improves long-term glycaemic control with a significantly lower rate of nocturnal hypoglycaemia compared with insulin glargine.

Insulin degludec: two-fold longer half-life and a more consistent pharmacokinetic profile than insulin glargine

T. Heise¹, U. Hövelmann¹, L. Nosek¹, S.G. Böttcher², C. Granhall³, H. Haahr³;

¹Profil Institut für Stoffwechselforschung, Neuss, Germany, ²Novo Nordisk

A/S, Aalborg, Denmark, ³Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Insulin degludec (IDeg) is a new-generation basal insulin that forms soluble multi-hexamers upon subcutaneous injection, resulting in an ultra-long and flat action profile. We describe the pharmacokinetic (PK) properties of IDeg in comparison to those of insulin glargine (IGlar) under steady-state (SS) conditions in people with type 1 diabetes.

Materials and methods: This was a randomised, double-blind, two-period, crossover study. Sixty-six people with type 1 diabetes (55 males/11 females, mean age 37 years, BMI 24.9 kg/m², HbA_{1c} 8.1%) received one of three fixed doses (0.4, 0.6 or 0.8 U/kg) of IDeg and IGlar once daily for 8 days with 7-21 days wash-out between treatments. A euglycaemic glucose clamp was performed on treatment Day 8 and PK samples were taken throughout each treatment period and for 120 h after the last dose.

Results: IDeg showed stable PK concentrations under steady-state conditions that showed minimal fluctuations and that increased proportionally with increasing dose. The serum exposure to IDeg was equally distributed between the first and the second 12 hours post-dosing (indicated by a ratio between AUC_{0-12h,SS} and AUC_{total,SS} of 0.5) whereas IGlar showed a higher exposure during the first 12 hours (AUC_{0-12h,SS} / AUC_{total,SS} = 0.6). Likewise, the cumulated AUC below and above the average glucose infusion rate (AUC_{GIR,SS}) was considerably lower for all doses of IDeg (0.25, 0.37, 0.38 mg/kg/min) than with IGlar (0.39, 0.54 and 0.73 mg/kg/min). IDeg was detectable in the serum for at least 120 h following the final dose, whereas, for most subjects, IGlar fell below the lower limit of quantification after 36-48 h post dosing. Mean terminal half-life was twice as long for IDeg than IGlar (25.4 vs. 12.5 h). Both insulin preparations were well tolerated and no safety concerns were identified.

Conclusion: IDeg has a half-life that is twice as long as IGlar, resulting in a more evenly distributed and stable pharmacokinetic profile for IDeg at steady state in people with type 1 diabetes.

Ultra-long pharmacokinetic properties of insulin degludec in adults with type 1 diabetes is preserved in children and adolescents after single-dose administration

T. Danne¹, T. Biester¹, S. Blaesig¹, R. Kerstin¹, B. Aschemeier¹, O. Kordonouri¹, C. Granhall², F. Søndergaard³, A. Francisco², H. Haahr²;

¹Diabetes-Zentrum für Kinder und Jugendliche, Hannover, Germany, ²Novo Nordisk A/S, Søborg, Denmark, ³Novo Nordisk A/S, Aalborg, Denmark.

Background and aims: The incidence of type 1 diabetes in children/adolescents is growing with a predicted increase of 70% in prevalent cases ≤ 15 years in Europe. Management of type 1 diabetes in children and adolescents requires continuous monitoring and frequent adjustment of basal and bolus insulin. Insulin degludec (IDeg) is a neutral soluble ultra-long-acting new-generation basal insulin with duration of action of more than 42h in adults, allowing flexible dosing at any time of the day with the possibility to change injection time from dose to dose. The primary objective of this trial was to investigate how the pharmacokinetic (PK) properties of IDeg in children and adolescents compare with those in adults after a single dose.

Materials and methods: This was a randomised, single-centre, double-blind, single dose, cross-over trial with IDeg and insulin glargine. 12 children, 13

adolescents and 12 adults (mean age 10.3 ± 1.1 , 14.3 ± 1.6 , and 25.6 ± 1.9 y; BMI 18.6 ± 1.9 , 21.5 ± 2.0 , and 25.3 ± 2.9 kg/m²; mean duration of diabetes 5.1 ± 2.4 , 5.9 ± 4.1 , and 13.8 ± 8.3 y; HbA_{1c} 7.7 ± 0.8 , 7.7 ± 0.5 , and 7.6 ± 1.0 %) completed the trial and were included in the PK evaluation. IDeg (100 U/ml) was administered as a single s.c. dose (0.4 U/kg). Blood samples for PK analyses were drawn over the first 48h, and again at 72h post-dosing.

Results: Duration of exposure to IDeg was ultra-long in children, adolescents and adults after a single dose (see mean profiles). IDeg was detected 72h after administration for all subjects. Total exposure to IDeg ($AUC_{IDeg,0-\infty}$) tended to be greater in children and adolescents than in adults based on pairwise comparisons (children/adults 1.48 [95% CI: 0.98;2.24], adolescents/adults 1.33 [95% CI: 1.08;1.64]). No statistically significant differences in maximum IDeg concentration ($C_{max,IDeg}$) were shown between children and adults (1.20 [95% CI: 0.90;1.60]) or adolescents and adults (1.23 [95% CI: 1.00;1.51]). There were no differences between age groups regarding the number of hypoglycaemic episodes, and no episodes of severe hypoglycaemia. No clinically significant changes in laboratory parameters, vital signs or physical examination were observed.

Conclusion: The ultra-long-acting properties of IDeg in adults are preserved in children/adolescents. Extent of exposure after a single fixed dose tends to be greater in children/adolescents than adults; as with other insulin products, IDeg should always be titrated according to individual requirements. IDeg is well tolerated and no safety issues are identified in this trial. Thus, paediatric studies investigating the potential clinical benefits of this ultra-long-acting basal insulin with unprecedented duration of action appear warranted.

Dashed line represents the lower limit of quantification

Does insulin detemir alter satiety or caloric intake to control weight?

M.R. Burge, S. Mitchell, M. Garimella;

Internal Medicine/Endocrinology, University of New Mexico Health Sciences Center, Albuquerque, USA.

Background and aims: Insulin detemir is a long-acting insulin analog that is weight-neutral compared with other long-acting insulins in patients with type 1 diabetes, but the mechanism for this observation is unknown. One mechanism may be an effect of detemir to enhance satiety. We hypothesized that type 1 diabetes patients would eat fewer calories when presented with a standardized buffet meal following a 24 hour fast when using insulin detemir as compared to insulin glargine.

Materials and methods: Ten subjects with C-peptide negative type 1 diabetes participated in a randomized, double-blind crossover study in which they received equivalent doses of either insulin detemir or glargine twice daily for at least 3 weeks. They were then admitted to the UNM Clinical Research Unit for a 24 hour fast, after which they were allowed to eat to satiety from a standardized, 10,000 calorie buffet without provision of rapid acting insulin. Measurement of caloric consumption following the fast, body composition by bioelectrical impedance, hunger assessment, and indirect calorimetry were performed. The serum satiety factors leptin, ghrelin and PYY were assessed at baseline, after the 24 hour fast, and after ingestion of the test meal.

Results: Subjects were aged 35 ± 11 years, had diabetes for 18 ± 11 years, had HbA_{1c} levels of 8 ± 1 % and BMI of 30 ± 8 kg/m². Long acting insulin doses

were 37 ± 26 units/day. Home glucose values did not differ during treatment between the insulins during the study (187 ± 254 detemir vs. 172 ± 269 mg/dl glargine; $p=0.21$), but short-acting insulin doses were higher on detemir (15 ± 10 vs. 13 ± 8 units/day; $p<0.001$). Hunger scores (68 ± 25 vs. 73 ± 24 ; $p=0.58$) and total energy ingested following the 24 hour fast (1418 ± 636 vs. 1357 ± 576 kcal; $p=0.63$) did not differ between insulin detemir and insulin glargine, respectively. Resting Energy Expenditure also did not differ (1405 ± 398 vs. 1457 ± 536 kcal/d; $p=0.63$). Results of satiety factors are shown in the table and did not differ significantly.

Conclusion: The weight-neutrality of insulin detemir in type 1 diabetes is not attributable to reduced caloric intake, and systemic satiety factors are unaffected by choice of long acting insulin.

Satiety Factors Before and After Fasting and Feeding

	Leptin (ng/ml)			PYY (pg/ml)			Ghrelin (pg/ml)

Multi-hexamer formation is the underlying basis for the ultra-long glucose-lowering effect of insulin degludec

P. Kurtzhals¹, T. Heise², H.M. Strauss¹, S.G. Böttcher³, C. Granhall⁴, H. Haahr⁴, I. Jonassen¹;

¹Novo Nordisk A/S, Måløv, Denmark, ²Profil Institut für Stoffwechselforschung, Neuss, Germany, ³Novo Nordisk A/S, Aalborg, Denmark, ⁴Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Insulin Degludec (IDeg) is a new-generation basal insulin that has been shown in clinical studies to have a flat and stable action profile and a lower risk of hypoglycaemia compared to other basal insulins. A continuous and sustained release of IDeg monomers into the circulation from a depot of soluble multi-hexamers that form after subcutaneous (s.c.) injection is considered to be the underlying mechanism behind the distinct characteristics of IDeg. Here we use transmission electron microscopy (TEM) to verify the formation of IDeg multi-hexamers under conditions mimicking the s.c. injection site, and investigate the pharmacodynamic consequences of IDeg multi-hexamer formation through use of the euglycaemic glucose clamp in people with type 1 diabetes.

Materials and methods: Transmission electron microscopy was used to visualise IDeg multi-hexamers. Samples of IDeg at a concentration of 2.5 mg/ml in a preparation containing five zinc ions per insulin hexamer were placed on formvar coated copper grids, stained with a 2.5 % (m/V) uranyl acetate solution and examined with a FEI Morgagni 268 electron microscope, operating at 80 kV. The duration of the glucose-lowering effect of IDeg was investigated in 42-h euglycaemic glucose clamps (Biostat; clamp blood glucose (BG) level: 5.5 mmol/l) conducted after 8 days of once-daily administration of IDeg (0.4, 0.6 or 0.8 U/kg) to people with type 1 diabetes.

Results: Under conditions mimicking the s.c. interstitial fluid, TEM revealed elongated structures with a uniform width (6.3 ± 0.9 nm) that was consistent with the expected width of insulin hexamers. No such structures were visible under conditions corresponding to the pharmaceutical IDeg formulation, indicating that multi-hexamers only form after s.c. injection. Addition of EDTA to chelate zinc ions disrupted the multi-hexameric structures. This demonstrates that multi-hexamer formation is reversible, and suggests that the gradual release of zinc ions from s.c. multi-hexamers leads to the release of IDeg monomers for absorption. In the euglycaemic glucose clamp experiments, the glucose-lowering effect of IDeg extended beyond 42 hours at all three doses. End of action (BG >8.3 mmol/l) did not occur within the 42-h clamp period for any of the subjects dosed with 0.6 or 0.8 U/kg IDeg, and only for three out of the 21 subjects dosed with 0.4 U/kg IDeg. Moreover, mean BG profiles measured over the 42-h clamp remained almost horizontal for the 0.6 and 0.8 U/kg dose groups showing that BG was controlled throughout.

Conclusion: The formation of soluble IDeg multi-hexamers at the subcutaneous injection site gives rise to an ultra-long glucose-lowering effect that extends beyond 42 h at clinically relevant doses in people with type 1 diabetes.

IDegAsp, a soluble insulin combination of ultra-long-acting insulin degludec and insulin aspart, used once daily in basal-bolus treatment with insulin aspart in type 1 diabetes

I. Hirsch¹, E. Franek^{2,3}, J.P. Courrèges⁴, H. Mersebach⁵, P. Dykiel⁶, B.W. Bode⁷;

¹School of Medicine, University of Washington, Seattle, USA, ²Central Clinical Hospital MSWiA, Warsaw, Poland, ³Medical Research Center, Polish Academy of Sciences, Warsaw, Poland, ⁴Diabetology and Vascular Disease Unit, General Hospital, Narbonne, France, ⁵Global Development, Novo Nordisk A/S, Søborg, Denmark, ⁶Novo Nordisk A/S, Malmö, Denmark,

⁷Atlanta Diabetes Associates, Atlanta, USA.

Background and aims: Insulin degludec (IDeg) is a new-generation basal insulin that forms soluble multi-hexamers upon subcutaneous (s.c.) injection, resulting in an ultra-long and flat action profile. Insulin degludec/insulin aspart (IDegAsp) is a soluble co-formulation of IDeg (70%) and insulin aspart (IAsp; 30%) designed to provide mealtime and basal insulin coverage. This phase 3, 26-week, open-label, treat-to-target trial investigated the efficacy and safety of IDegAsp in people with type 1 diabetes inadequately controlled on any insulin.

Materials and methods: 548 people with type 1 diabetes and inadequately controlled HbA_{1c} (mean: age 41 years; HbA_{1c} 8.3%; FPG 10.5 mmol/l) on any insulin-based regimen were randomised 2:1 to receive IDegAsp or insulin detemir (detemir). IDegAsp was administered once-daily and could be given at any meal, with IAsp at remaining meals. Detemir was administered according to label with IAsp at all meals.

Results: Similar proportions of participants completed the trial (87% for IDegAsp and 86% for detemir). IDegAsp and detemir treatment resulted in similar improvements in HbA_{1c} (0.73 %-point reduction for IDegAsp vs. 0.68 %-point reduction for detemir; estimated treatment difference (ETD) IDegAsp-detemir: -0.05 %-point [95% CI: -0.18; 0.08]). FPG was reduced by 1.6 mmol/l with IDegAsp and by 2.4 mmol/l with detemir; ETD IDegAsp-detemir: 0.23 mmol/l [-0.46; 0.91] p=0.52). Confirmed hypoglycaemia (PG <3.1 mmol/l or severe) was reported for ~94% of subjects in both groups; rates were similar (39 vs. 44 episodes/patient-year; estimated rate ratio (ERR) IDegAsp/IDet: 0.91 [95% CI: 0.76; 1.09] p=0.27). The rate of nocturnal confirmed hypoglycaemia (confirmed hypoglycaemia occurring between 00:01-05:59 h) was 37% lower with IDegAsp (3.7 vs. 5.7 episodes/patient-year; ERR: 0.63 [95% CI: 0.49; 0.81] p=0.0003). Mean total daily insulin doses were similar in both groups by the end of the study (0.86 U/kg vs. 1.00 U/kg, for IDegAsp and detemir groups, respectively). After 26 weeks, mean body weight had increased from 76.5 to 78.9 kg (IDegAsp) vs. 76.1 to 77.5 kg (detemir); there was less weight gain in the detemir group compared with the IDegAsp group (ETD: IDegAsp-detemir: 1.0 kg [0.38; 1.69] p=0.0021). Overall rates of adverse events were similar between groups with no treatment-specific pattern or clustering.

Conclusion: IDegAsp dosed once daily at any meal with IAsp at the remaining meals provided similar glycaemic control to detemir with mealtime IAsp. The IDegAsp regimen was associated with significantly less nocturnal hypoglycaemia, and has the added convenience of fewer daily injections than conventional basal-bolus therapy.

Clinical Trial Registration Number: NCT00978627

Supported by: Novo Nordisk

Materials and methods: Participants (n=33) (mean age of 40 ± 10 years, diabetes duration of 20 ± 10 years, HbA_{1c} 7.3 ± 0.8% and C-peptide of <0.3 nmol/l) each underwent 8-day treatment periods with 0.4 U/kg U100 and U200 given once daily with insulin aspart at mealtimes. On Day 8, participants fasted and a glucose clamp procedure was performed with euglycaemia (5.5 mmol/l) established and maintained using a variable intravenous glucose infusion over 5 hours, whereupon IDeg (0.4 U/kg U100 or U200) was injected at the usual dosing time and the clamp maintained for 26 hours. The primary endpoint was AUC_{GIR,total,SS}.

Results: Comparable glucose infusion rates (GIR) were observed for U100 and U200 (AUC_{GIR} [mg/kg]: 2255 vs. 2123) and the mean ratio of U200/U100 for the primary endpoint (AUC_{GIR,total,SS}) was 0.94 [95% CI: 0.86; 1.03]. A post-hoc analysis showed bioequivalence between U100 and U200, as the 90% CIs of the ratios for AUC_{IDeg,total,SS} and C_{max,IDeg,SS} were within the interval 0.80-1.25 (AUC_{IDeg,total,SS} U200/U100 ratio 0.99 [0.91; 1.07] and C_{max,IDeg,SS} U200/U100 ratio 0.93 [0.84; 1.02]). Both formulations were well tolerated, and there were no marked differences in distribution of adverse events or hypoglycaemic events.

Conclusion: Insulin degludec U100 and U200 formulations are bioequivalent and have similar pharmacodynamic profiles at steady state, suggesting that they can be used interchangeably in clinical practice.

Ultra-long-acting insulin degludec: bio-equivalence and similar pharmacodynamics shown for two different formulations (U100 and U200)

S. Korsatko¹, S. Deller¹, S. Zahiragic¹, J. Mader¹, K. Neubauer¹, C. Adrian², H. Thomsen³, H. Haahr², T. Pieber¹;

¹Department of Internal Medicine, Division of Endocrinology and Metabolism, Medical University of Graz, Austria, ²Novo Nordisk A/S, Søborg, Denmark, ³Novo Nordisk A/S, Aalborg, Denmark.

Background and aims: Insulin degludec (IDeg) is a new-generation basal insulin that forms soluble multi-hexamers upon subcutaneous injection resulting in a depot from which IDeg is continuously and slowly absorbed to provide an ultra-long action profile. Two different formulations, 100 U/ml (U100) and 200 U/ml (U200), have been developed, the aim of the latter being to enable higher doses to be administered in smaller injection volumes. A double-blind, crossover, randomised study was conducted to characterise the pharmacodynamic response and pharmacokinetic exposure to U100 and U200 under steady-state (SS) conditions in people with type 1 diabetes.

Durability of glycaemic control with insulin lispro mix 25 vs glargine for older patients with type 2 diabetes

L. Jovanovic¹, A. Peters², H. Jiang³, D. Hardin³;

¹Sansum Diabetes Research Institute, Santa Barbara, ²University of Southern California Keck School of Medicine, Los Angeles, ³Lilly USA, LLC, Indianapolis, USA.

Background and aims: Few clinical trials have evaluated long-term durability of glycaemic control in older patients. This post-hoc analysis compared durability of glycaemic control of 2 starter insulin regimens in older patients (≥ 65 years of age) in the DURABLE Trial maintenance phase: twice-daily insulin lispro mix 25 (LM25; 25% insulin lispro, 75% insulin lispro protamine suspension) vs once-daily insulin glargine (GL), added to ≥ 2 oral antihyperglycaemic medications in insulin-naïve patients with type 2 diabetes.

Materials and methods: In the 24-week initiation phase, patients were randomised to LM25 vs GL, after which those with $HbA_{1c} \leq 7.0\%$ entered a 24-month maintenance phase. Among the 892 patients in the maintenance phase, 224 were older (≥ 65 years of age) (LM25, $n=133$; GL, $n=91$). The present analysis primarily compared duration of maintaining HbA_{1c} goal ($HbA_{1c} \leq 7.0\%$, or $HbA_{1c} > 7.0\%$ with $< 0.4\%$ increase from last $HbA_{1c} \leq 7.0\%$) for LM25 vs GL among older patients. Analyses were also conducted for older patients achieving 24-week HbA_{1c} targets $\leq 6.5\%$ (LM25, $n=72$; GL, $n=39$).

Results: Baseline characteristics were similar for LM25 vs GL. The mean age was 69.5 years, baseline weight 89.5 kg, BMI 32.0 kg/m², duration of diabetes 11.8 years, and female 40.2%. Median time of maintaining HbA_{1c} goal (see Figure) was significantly longer in LM25 (19.6 months; 95%CI=14.0, 26.3) vs GL (15.4 months; 95%CI=9.2, 17.3; $p=0.007$) and more patients in LM25 maintained HbA_{1c} goal vs GL (49.2% vs 30.4%; $p=0.003$). HbA_{1c} reduction from baseline was significantly greater in LM25 vs GL ($-1.56 \pm 0.10\%$ vs $-1.24 \pm 0.11\%$; $p=0.003$), including older patients with $HbA_{1c} \leq 6.5\%$ ($-1.61 \pm 0.14\%$ vs $-1.34 \pm 0.12\%$; $p=0.049$). Endpoint fasting blood glucose was similar in LM25 vs GL, but post-meal glucose was significantly lower in LM25 vs GL (8.82 ± 0.19 mmol/L vs 9.53 ± 0.25 mmol/L; $p=0.017$), including older patients with $HbA_{1c} \leq 6.5\%$ (8.33 ± 0.20 mmol/L vs 9.31 ± 0.41 mmol/L; $p=0.016$). Overall hypoglycaemia rates and severe hypoglycaemia incidence were similar in LM25 vs GL, including older patients with $HbA_{1c} \leq 6.5\%$. Weight gain was significantly greater in LM25 vs GL (5.47 ± 0.49 kg vs 3.10 ± 0.53 kg; $p=0.001$), but was similar in older patients with $HbA_{1c} \leq 6.5\%$. Daily insulin doses were significantly higher in LM25 vs GL (0.41 ± 0.02 IU/kg/day vs 0.32 ± 0.02 IU/kg/day; $p<0.001$); however, were similar for LM25 vs GL in older patients with $HbA_{1c} \leq 6.5\%$.

Conclusion: In the older population, LM25 resulted in longer durability of glycaemic control, and a greater number of patients maintaining HbA_{1c} goal vs GL. LM25 was associated with more weight gain and modestly higher daily insulin doses; hypoglycaemia rates and incidence of severe hypoglycaemia were similar for LM25 vs GL. Older patients with $HbA_{1c} \leq 6.5\%$ had similar results, including no increase in hypoglycaemia with LM25 vs GL.

Factors associated with HbA_{1c} reduction in Asian patients with T2DM: an analysis of the FINE Asia registry

K. Tan Eng Kiat¹, L. Ji², K. Suastika³, J. Wang⁴, E. Wang⁵, J. Lin⁶, S.-T. Tsai⁷;

¹Mount Elizabeth Medical Centre, Singapore, ²Peking University People's Hospital, Beijing, China, ³Udayana University / Sanglah Hospital, Bali, Indonesia, ⁴Jinling Hospital, Nanjing, Jiangsu, China, ⁵sanofi-aventis, Bridgewater, USA, ⁶Novosys Health, Flemington, USA, ⁷Taipei Veterans General Hospital, Taiwan.

Background and aims: Asian patients with type 2 diabetes mellitus (T2DM) who were uncontrolled on oral antihyperglycemic drugs (OADs) were recruited from 11 countries in the FINE Asia registry. The study included 2921 (50.3% female) patients, with a mean (SD) age of 56.4 (11.2) years and a T2DM duration of 9.3 (6.5) years. A total of 2196 (75.2%) patients were prescribed insulin glargine, 637 (21.8%) NPH insulin, and 75 (2.6%) insulin detemir. After 6 months of basal insulin therapy with or without concomitant OADs, there was marked improvement in glycaemic control. Overall, HbA_{1c} decreased from 9.8 (1.6) to 7.7 (1.4) % at Month 6. This analysis aimed to identify factors responsible for the HbA_{1c} change.

Materials and methods: Multivariate generalized linear model (GLM) regression was used where independent covariates included age, gender, initiating insulin type and other demographic and clinical characteristics related to diabetes management; $p < 0.05$ was considered statistically significant. In calculating p values, the statistical model factored the impact of different sample sizes.

Results: There were 2679 patients with HbA_{1c} values at baseline and Month 6 who were included in the analysis. Initiating insulin with detemir ($n = 61$) vs glargine ($n = 2016$) was associated with less reduction in HbA_{1c} ($\Delta = -0.50$; 95% confidence interval [CI]: -0.17, -0.83; $P = 0.003$), as was initiating with NPH ($n = 589$) vs glargine ($\Delta = -0.36$; 95% CI: -0.23, -0.49; $P < 0.001$). Older age was associated with greater reduction in HbA_{1c} ($\Delta = 0.008$; 95% CI: 0.003, 0.013; $P = 0.002$) as was a higher HbA_{1c} value at baseline ($\Delta = 0.8$; 95% CI: 0.77, 0.83; $P < 0.001$). A longer history of previous OAD usage was associated with less reduction in HbA_{1c} ($\Delta = -0.026$; 95% CI: -0.052, -0.0001; $P = 0.049$) as was female gender ($\Delta = -0.19$; 95% CI: -0.06, -0.32; $P = 0.005$). There was no significant association of HbA_{1c} reduction with baseline body weight, fasting blood glucose, blood pressure or insulin dose or with duration of diabetes.

Conclusion: Among patients with T2DM in Asia, the following factors were associated with greater HbA_{1c} reduction: initiation with glargine vs NPH or detemir, older age, and higher HbA_{1c} at baseline. Identification of these and other factors may support better glycaemic control.

Pharmacodynamics of basal insulins NPH, glargine and detemir in type 2 diabetes mellitus: effects of adiposity

F. Porcellati, P. Lucidi, P. Rossetti, P. Candeloro, A. Marinelli Andreoli, P. Cioli, G.B. Bolli, C.G. Fanelli;
Internal Medicine, University of Perugia, Italy.

Background and aims: The role of adiposity of Type 2 diabetes (T2DM) on pharmacodynamics (PD) of basal insulins NPH, detemir (Det) and glargine (Gla) is not known.

Materials and methods: To examine the question, we studied the relationship between PD and body mass index (BMI), in 18 subjects with Type 2 diabetes (age 60 ± 7 yrs, BMI 29.1 ± 3.2 kg/m², A1C $7.5 \pm 0.6\%$, treatment insulin+oral hypoglycemic agents [mean \pm SD]). PD results (glucose infusion rate over 32h [GIR_{0-32h} , AUC_{0-32h}]) were generated by a randomized, single-blind, cross-over study using the euglycemic clamp (100 mg/dl) for 32 h after s.c. injection of 0.4 U/kg at 22.00 h of either NPH or Gla or Det, after 1-week treatment with each insulin, and analyzed according to BMI.

Results: Based on BMI status (<29 and >29 kg/m², i.e. below and above the median BMI of the overall group), GIR was greater in people with BMI <29 kg/m² compared to those with BMI >29 kg/m² although statistical significance was achieved only with Det (1564 ± 649 and 598 ± 604 mg/Kg, respectively, $p=0.03$) and not with NPH (1282 ± 532 and 1058 ± 859 mg/Kg) and glargine (1668 ± 807 and 1408 ± 563 mg/Kg), (both $p>0.2$). A multiple regression analysis after correcting for age and duration of diabetes revealed a statistically significant inverse correlation between BMI and GIR only with Det ($r=-0.68$, $p=0.003$), but not with Gla ($r=-0.41$, $p=0.11$) and NPH ($r=-0.37$, $p=0.15$). In addition, a positive correlation was found between BMI and endogenous glucose production (EGP) with NPH and Det ($r=0.66$, $p=0.005$ and $r=0.62$, $p=0.011$, respectively) but not with Gla ($r=0.35$, $p=0.17$). As expected, PD of basal insulins in T2DM is inversely correlated with adiposity, likely because of greater insulin resistance in BMI >29 kg/m².

Conclusion: Among the three insulins examined, Det exhibits the lowest PD action and weakest effect in restraining EGP as adiposity increases, as compared to NPH and Gla. PD of Gla (mediated by greater suppression of EGP) is less affected by adiposity as compared to NPH and to greater extent, Det. These findings may explain, at least in part, the need for higher doses of Det as compared to Gla in clinical trials in obese T2DM when the two basal insulins are titrated to same target A1C.

Ultra-long-acting insulin degludec has a flat and stable glucose-lowering effect

L. Nosek¹, T. Heise¹, S.G. Böttcher², H. Hastrup³, H. Haahr³;
¹Profil Institut für Stoffwechselforschung, Neuss, Germany, ²Novo Nordisk A/S, Aalborg, Denmark, ³Novo Nordisk A/S, Søborg, Denmark.

Background and aims: Insulin degludec (IDeg) is a new-generation, ultra-long-acting basal insulin that forms soluble multi-hexamers upon subcutaneous injection, resulting in a depot from which IDeg is continuously and slowly absorbed into the circulation. In this trial we investigated the dose-response relationship of IDeg at steady state (SS) in people with type 2 diabetes.

Materials and methods: In this double-blind, two-period, cross-over trial, the dose-response relationship of three doses of IDeg (0.4, 0.6 and 0.8 U/kg) was evaluated at steady state. Participants (insulin-treated people with type 2 diabetes without concomitant oral anti-diabetic agents, $n=49$; mean: age, 58.7 years; BMI, 29.6 kg/m²; HbA_{1c}, 7.6%; duration of diabetes, 14.1 years) were given IDeg once-daily for 6 days, with a washout period of 13–21 days between treatments (starting after the last dosing on Day 6). Following dosing on Day 6, subjects underwent a euglycaemic glucose clamp (Biostat; clamp blood glucose level: 5 mmol/l). Pharmacokinetic samples were taken up to 120 h after the last injection of IDeg.

Results: For all dose levels, mean 24-h glucose infusion rate (GIR) profiles were flat and stable (Figure 1). Total glucose-lowering effect ($AUC_{GIR, total, SS}$) increased linearly with increasing dose. Over 24 h, the glucose-lowering effect of IDeg was evenly distributed between the first and second 12 h for all three dose levels ($AUC_{GIR, 0-12h, SS} / AUC_{GIR, total, SS} = 0.5$). The blood glucose levels of all participants stayed very close to the clamp level until the end of the experiment (mean blood glucose levels in the last 10 min of a 24-h dosing interval were 5.0–5.1 mmol/l for all IDeg doses). The terminal half-life estimated across the three dose levels after the last dose was 25.1 hours. IDeg was well tolerated and no safety concerns were identified.

Conclusion: IDeg has a flat and stable blood glucose-lowering effect, and a duration of action beyond 24 h in people with type 2 diabetes.

Metabolism of insulin glargine after subcutaneous injection of therapeutic dose in type 2 diabetes mellitus

P. Lucidi¹, F. Porcellati¹, P. Rossetti¹, P. Candeloro¹, A. Marinelli Andreoli¹, A. Frick², R. Schmidt², G.B. Bolli¹, C.G. Fanelli¹;

¹Internal Medicine, University of Perugia, Italy, ²Sanofi-Aventis Deutschland GmbH, Frankfurt, Germany.

Background and aims: After subcutaneous (sc) injection *in vivo*, the long-acting insulin analog glargine (GLA) undergoes a sequential cleavage of the carboxy terminus of the B-chain forming metabolites M1 and M2 that lack the di-arginine (M1 after removal of the two arginines, M2 with additional deamination of threonine at position B30). M1 and M2 have the same metabolic properties as human insulin (HI) and do not differ from HI in affinity for IGF-IR. Currently, there are no data about dynamics and relative percentage of plasma M1 and M2 vs GLA after sc dose in patients with type 2 diabetes (T2DM).

Materials and methods: GLA, M1, and M2 plasma concentrations were determined from samples obtained from a single-center, 32h euglycemic glucose clamp study, where 18 subjects with T2DM received a single sc dose of 0.4 U/kg GLA after one week of daily administration. Data from 9 subjects and 31h glucose clamp, are here reported (mean \pm SD: BMI 29.3 ± 3 kg/m²; A1C $7.4 \pm 0.0\%$, diabetes duration 13 ± 10 yrs). GLA, M1, and M2 were extracted using immunoaffinity columns and quantified by a specific liquid chromatography tandem mass spectrometry assay, without cross-reactivity to endogenous human or other insulins. The limit of quantitation (LOQ) was 0.2 ng/ml (~ 33 pmol/l).

Results: GLA was detected in 5 of the 9 subjects and only at a few time points; M2 was not detected at all, whereas M1 was detected in all subjects. M1, but not GLA, was detected at baseline (median: 44 pmol/l; 25th to 75th percentile: 19 to 131 pmol/l), likely reflecting GLA injected 24h before. In fact, 24h post-injection values were similar to baseline values (60; 52 to 118 pmol/l). The median GLA PK-AUC₀₋₃₁ was 171 pmol·h/l (0 to 314) and M1 PK-AUC₀₋₃₁ was 2166 pmol·h/l (1622 to 4955). GLA C_{max} was 40 pmol/l (0 to 48) and M1 C_{max} was 129 pmol/l (75 to 207).

Conclusion: After sc injection of a therapeutic dose, GLA is minimally detectable in blood with low peak concentration and up to only 9 hours (3.5 to 14.5), whereas its metabolite M1 accounts for most ($\sim 90\%$) of the plasma insulin concentration up to 31 h. Additional studies using a higher dose of GLA might provide further insights into the metabolism of GLA in T2DM

Insulin glargine as well as metformin therapy improves myocardial function in patients with coronary artery disease and impaired glucose tolerance or early type 2 diabetes

T. Siegmund, P.-M. Schumm-Draeger, K. Traore, H. von Bibra;
Endocrinology, Diabetes and Vascular Medicine, Klinikum Munich GmbH, Germany.

Background and aims: Patients with coronary artery disease (CAD) have a 40–60% probability of an impaired glucose metabolism. The risk for cardiovascular disease is already increased in patients with pre-diabetes, e.g. impaired glucose tolerance (IGT) and this risk increases further with type 2 diabetes (T2D). Treatment algorithms for patients with prediabetes do not exist. Accordingly, we created this hypothesis creating, randomized controlled trial about effects of a medical treatment in patients with IGT or early T2D with CAD focusing on cardiovascular function and on postprandial (pp) effects of this therapy.

Materials and methods: Inclusion criteria were CAD with IGT or early diabetes (either diet alone or a maximum of one oral antihyperglycemic agent). We recruited 28 patients, age 66 ± 10 years (IGT $n=12$, diabetes $n=16$ with a duration of 3 ± 3 years). They were randomized to metformin (Met), 2000 mg daily or insulin glargine (IG) to be titrated to a fasting glucose ≤ 110 mg/dl. Blood tests and echocardiography were done fasting and 2 hours after a standardized carbohydrate (48g) meal at baseline and 4, 12 and 24 weeks. Systolic (S') and diastolic cardiac function (E') were assessed by pulsed tissue Doppler. Age, HOMA, concomitant medication and the history of CAD were comparable between the groups.

Results: Patients on IG ($n=13$, mean daily dose 17 IU) reported no hypoglycaemic events or other side effects. Two patients on Met ($n=15$, mean daily dose 1518 mg) reported mild abdominal side effects. S' remained unchanged in both groups, but E' improved significantly in IG by $12 \pm 18\%$ ($p<0.03$) and in Met by $7 \pm 12\%$ ($p<0.05$) in the fasting state and also pp ($p<0.05$ and <0.02 respectively). Systolic blood pressure decreased in IG and Met (by 11 ± 14 , $p<0.02$ and by 15 ± 18 mmHg, $p<0.01$) as did diastolic blood pressure ($p<0.04$ and <0.03). The intergroup difference between the observed reduction of intima media thickness (IMT) in IG vs. the observed increase in Met was significant ($p<0.04$). HbA1c decreased significantly in IG and Met (from 6.7 ± 1.1 to $6.3 \pm 1.1\%$, $p<0.04$ and from 6.1 ± 0.8 to $5.8 \pm 0.5\%$, $p<0.05$). In the IG group, this was associated with a trend to improved pp glucose (from 207 ± 96 to 161 ± 43 mg/dl, $p<0.052$) and reduced pp increase of glucose (from 72 ± 69 to 49 ± 40 mg/dl, $p<0.04$) and in Met with a trend to improved fasting glucose (from 124 ± 28 to 117 ± 15 mg/dl, $p<0.09$). Lipid profile and hsCRP were unchanged in both groups.

Conclusion: In patients with coronary artery disease and impaired glucose tolerance or early T2D, treatment with insulin glargine or metformin improved diastolic cardiac function, blood pressure and HbA1c. These results support efforts to start improving glucose metabolism in the early stage of pre-diabetes and diabetes. Given the prognostic importance of diastolic function and the relative improvement of intima media thickness with insulin glargine but not metformin, these results deserve further evaluation of cardiovascular endpoints and clarification of the underlying pathophysiological mechanisms.

Safety and efficacy of NPH after switching from insulin glargine in Canadian patients

L.D. Berard^{1,2}, V.C. Woo^{1,2};

¹Diabetes Research Group, WRHA Health Sciences Centre Winnipeg, Canada, ²University of Manitoba, Winnipeg, Canada.

Background and aims: Due to provincial reimbursement restrictions, ACCORD patients treated with insulin glargine (IG) or insulin detemir (ID) will be required to switch to NPH. Switching takes place outside of the close monitoring of the trial. It was therefore decided to conduct a study to evaluate patient safety when IG is replaced with NPH.

Materials and methods: Patients leaving the ACCORD study treated with the long acting analogue insulins were randomized 1:1 to either IG or NPH insulin. Patients randomized to NPH were to use 80% of the prior IG dose, 80% of the prior ID dose administered qd, and 50% of the prior ID dose administered bid. It was investigator to administer NPH qd or bid. Follow

up as per clinical practice. Deviations would be captured as additional health resource utilization (HRU). The sample was predetermined by the number of available patients finishing ACCORD and not determined by the selection of primary outcome variable. As consequence, results are being presented using descriptive statistics. The primary outcome variable was the rate of confirmed symptomatic hypoglycemic events. Secondary outcomes included, rate of severe and nocturnal hypoglycemia, change from baseline in hemoglobin A1c (A1c), fasting blood glucose (FBG), weight and change from baseline in treatment satisfaction as measured by the status and change Diabetes Treatment Satisfaction Questionnaires (DTSQ). Poisson regression was used to analyze the semi-annual rate of symptomatic hypoglycemia and analysis of covariance was used to analyze the changes from baseline for the secondary variables. Analysis of covariance with treatment as a fixed effect and baseline value for the variable being analyzed was used to analyze change from baseline for the secondary variables.

Results: 32 patients randomized to IG and 34 to NPH both arms were comparable with respect to weight (median 98.25 kg), A1c (median 7.9%), FBG (7.9 mmol/L) and use of meal time insulin (59%). Median dose for prior IG was 50 units (range 8 to 140) and comparable for both treatment groups. Median dose for prior ID was 58 units (range 7 to 150). The 4 patients previously treated with ID were all randomized to the IG arm. Median doses of IG at 3 and 6 months were 42 and 47 units, respectively. Median doses of NPH at 3 and 6 months were 38 and 50 units, respectively. IG and NPH were administered bid in 4 and 2 patients, respectively. In all but one instance, the prior insulin had been administered bid. The semiannual rates (\pm se) per 100 patients for symptomatic hypoglycemia were 37.5 (2.2) IG and 31.1 (2.1) NPH. On the other hand, the semiannual rates for severe hypoglycemia per 100 patients were 2.7 (0.6) IG and 6.2 (0.9) NPH. There was no difference between the two groups for nocturnal hypoglycemia. The mean (\pm se) A1c decreases from baseline were -0.34% (0.11) IG and -0.01% (0.10), but no difference between treatments for FBG and weight. There was greater treatment satisfaction for the IG arm as measured by the change from baseline in the DTSQs and DTSQc. There was no difference observed for HRU between the two arms.

Conclusion: In this study of 66 randomized patients who had recently exited ACCORD, switching to NPH after having been previously treated with IG and ID, resulted in more than doubling the rate of severe hypoglycemia and less metabolic control. This, however, did not result in measurable difference in HRU.

Development of a novel insulin glargine chemiluminescent assay

G.J. Dunseath¹, S. Woodhead², A. Woodhead², K. Smith³, C. Popham⁴, S. Bourne⁴, S. Luzzio¹;

¹Diabetes Research Group, Swansea University, ²Invitron Ltd, Monmouth,

³School of Chemistry, Cardiff University, Swansea, ⁴Immune Systems Ltd, Paignton, UK.

Background and aims: The long acting insulin analogue, insulin glargine, differs from human insulin by the addition of two arginine residues to the C-terminus of the B chain and the substitution of asparagine with glycine at the C-terminal end of the A chain. In most insulin assays, the consequence of these small changes is that glargine is either not measured or is measured with variable cross-reactivity. This makes it difficult to interpret the results when using insulin assays. Our aim was to develop a specific immunochemiluminometric (ICMA) assay using a solid phase capture antibody and a second, acridinium ester labelled, antibody for analysis of insulin glargine.

Materials and methods: We have developed a new monoclonal antibody to insulin glargine (RR19.5). The antibody was raised to a 13 amino acid peptide sequence, representing the C-terminus of the B-chain of glargine and coupled to bovine thyroglobulin carrier protein. RR19.5 was employed as either the solid phase capture antibody or as the labelled antibody, with 3B1, an antibody to insulin, as the corresponding antibody. Insulin glargine standards in the range of 0 - 250mU/L were prepared by diluting medicinal insulin glargine. Optimum assay format and incubation conditions, as demonstrated by the greatest relative light units (RLU) at the highest dose, with low background RLUs were determined. Cross-reactivity with human insulin and other insulin analogues was also determined.

Results: All assay formats produced dose responses to increasing insulin glargine standards. The optimum incubation conditions were found to be a single, 24 hour incubation at 4°C, employing the glargine specific RR19.5 as the solid phase antibody and the insulin antibody 3B1 as the label. Which-

ever assay format was used, cross reactivity was <3.5% for actrapid (human insulin), <3% for insulin glulisine <1.5% for insulin aspart, <1.5% for insulin detemir and <0.25% for insulin lispro.

Conclusion: We have developed a simple assay, specific for insulin glargine, that may prove useful in clinical applications and pharmaceutical development.

Novel indices for quantitative assessment of flatness of the time action profile of a basal insulin

L. Mixson¹, R. Shankar², A. Harman³, C. Dehn⁴, C. Beals³, H.O. Steinberg², D.E. Kelley², S.S. Shankar³;

¹Biostatistics, Merck Research Laboratories, Rahway, USA, ²Diabetes and Endocrinology, Merck Research Laboratories, Rahway, USA, ³Experimental Medicine, Merck Research Laboratories, Rahway, USA, ⁴Metabolic Research, ICON Development Solutions, Manchester, UK.

Background: Several quantitative parameters are available to define the time-action profile of a basal insulin. However, flatness a key feature of the TAP, is still largely determined qualitatively by visual inspection of the shape of the graphical representation of the time course profiles of glucose infusion rates (GIR) during an isoglycemic clamp. We propose 2 indices based on GIR excursion in an IGC, that could provide quantitative measures of flatness, 1) Mean Amplitude of GIR Excursion (MAGIRE), where excursions (absolute change from peak to nadir and vice versa) of GIR > 1 SD above mean GIR are presented as an average over the duration of action, and 2) Continuous Overlapping Net GIR (CONGIR), where for each observation after the first n hours of observations, the difference between the current GIR measurement and that in preceding hours is calculated. CONGIRn = SD of the differences and n = lag time (hours).

Materials and methods: Data from an open label test-retest time action profile assessment of a single subcutaneous dose of 0.4 units/kg of insulin glargine in a 30-hour isoglycemic clamp in 16 lean healthy subjects were analyzed, using the qualitative and indices-based approaches, and compared.

Results: Wherever the shape of graphical representation (Figure 1) of the time action profile was flat (Part B: 8–24 hrs), the calculated indices for both MAGIRE and CONGIRn were statistically significantly less than in periods where the shape was not flat (rapid change towards a peak) (Part A: 0–8 hrs). Thus MAGIRE was 0.75 in Part B vs 1.93 in Part A ($P < 0.001$), and CONGIR_{0.5} was 0.08 in Part B vs 0.13 in Part A ($p < 0.01$), indicating quantitatively more flat profiles in Part B vs Part A (see Figure 1).

Conclusion: These data suggest that these novel indices may provide a quantitative means for assessment of the flatness of the time action profile of a basal insulin. Further refinement of such indices could enable more accurate comparisons between basal insulins. Figure 1. Graphical Representation of the Time Action Profile of a Basal Insulin.

Role of 12-lipoxygenase in slit diaphragm protein nephrin and P-cadherin expression in type 2 diabetic glomeruli

Y.-J. Wang¹, Z.-G. Xu², C.-S. Zang², Y. Yin³, Q.-Y. Guo⁴;

¹Department of Endocrinology, ²Department of Nephrology, ³Norman Bethune College of Medicine ⁴Department of Nephrology, Jilin University, Changchun, China.

Background and aims: 12-lipoxygenase (12-LO) was implicated in the development of diabetic nephropathy, in which the proteinuria was thought to be associated with a decreased expression of glomerular slit diaphragm protein nephrin and P-cadherin. Therefore, we investigated the role of 12-LO in the glomerular nephrin and P-cadherin expression in type 2 diabetic rats according to the glomerular sizes.

Materials and methods: 1) Rats fed with high-fat diet for 6 weeks were treated with low-dose streptozotocin. Once diabetes onset, diabetic rats were treated with 12-LO inhibitor cinnamyl-3,4-dihydroxy-cyanocinnamate (CDC) for 8 weeks. 2) Rats were randomly assigned to receive either 12(S)-HETE infusion or vehicle for 7 days by osmotic minipumps. 3) Rats were randomly assigned to receive either angiotensinII (AngII) infusion or vehicle by osmotic minipumps for 14 days. Glomeruli were isolated with a sieving method, using sieves with pore sizes of 250, 150, 125, and 75µm. We classified glomeruli into small (on the 75µm sieve) and large glomeruli (on the 125µm sieve) groups. Then, glomeruli were frozen in liquid nitrogen and stored at -70°C. RT-PCR, Western blotting, and immunofluorescent staining were used for mRNA and protein expressions of slit diaphragm protein and AngII type 1 receptor (AT1).

Results: We found that CDC did not affect the glucose levels but completely attenuated diabetic increases in glomerular volume and proteinuria. Diabetes significantly decreased the P-cadherin mRNA and protein expressions and increased the AT1 mRNA and protein expressions in the glomeruli compared to the control ($p < 0.01$). These changes were significantly prevented by CDC and recaptured by direct infusion of 12-LO product [12(S)-HETE] to normal rats for 7 days. The decreased P-cadherin expression was similar between large and small glomeruli, but the increased AT1 expression was significantly higher in the large than in the small glomeruli from diabetic and 12(S)-HETE-treated rats ($p < 0.01$). Nephrin mRNA and protein expressions were significantly reduced in the diabetic large glomeruli compared to the diabetic small glomeruli and control glomeruli ($p < 0.05$). In contrast, nephrin expression was significantly higher in the diabetic small glomeruli compared to diabetic large glomeruli and control glomeruli ($p < 0.05$). These changes were significantly prevented by CDC treatment. Direct infusion of normal rats with AngII for 14 days significantly decreased the glomerular P-cadherin expression compared to the control ($p < 0.01$). Direct infusion of normal rats with AngII and 12(S)-HETE significantly decreased large glomerular nephrin expression compared to the control ($p < 0.05$). However, small glomerular nephrin expression was increased after AngII and 12(S)-HETE treatment compared to the control ($p < 0.05$).

Conclusion: These results suggest that nephrin expression, but not P-cadherin expression, varies among the different sizes of glomeruli under type 2 diabetic conditions. Diabetic proteinuria is mediated by the activation of 12-LO-AT1 pathway that is partially attributed to the decreased glomerular nephrin and P-cadherin expression.

Prediabetic nephropathy caused by high-fat diet: relation to oxidative stress

H. Shevalye¹, S. Lupachyk¹, P. Watcho¹, R. Stavniichuk¹, K. Khasim², H.E. Abboud², I.G. Obrosova¹;

¹Pennington Biomedical Research Center, Baton Rouge, ²Medicine, University of Texas Health Science Center, San Antonio, USA.

Background and aims: Both experimental and clinical studies suggest that diabetes-like complications develop at the prediabetic stage, prior to the development of overt hyperglycemia. The present study was aimed at characterizing renal changes in high-fat diet (HFD) fed mice, a model of prediabetes and alimentary obesity. We also evaluated the link between prediabetic kidney disease and oxidative stress, known to play a pivotal role in functional

and morphological manifestations of nephropathies, associated with both Type 1 and Type 2 diabetes.

Materials and methods: Male C57Bl6/J mice were fed normal mouse chow or high-fat (58 kcal% fat) diet for 16 wks. Urinary albumin and 8-isoprostane were evaluated by ELISA. Renal cortex TGF- β , VEGF, 4-hydroxynonenal adduct, and 12(S)hydroxyeicosatetraenoic acid [12(S)HETE] concentrations were measured by ELISA; CHOP, phospho-eIF2 α , and total eIF2 α (markers of endoplasmic reticulum stress), as well as nephrin, and 12/15-lipoxygenase expression by Western blot analyses; glucose and sorbitol pathway intermediates by enzymatic spectrofluorometric assays; NAD(P)H oxidase activity by chemiluminometry; PAS-positive substance and collagen deposition by histochemistry; and podocyte counts by immunohistochemistry.

Results: HFD feeding resulted in 46% increase in body weight, impaired glucose tolerance, and hyperinsulinemia. Kidney weight was increased by 11%. HFD-fed mice displayed polyuria, 2.7-fold increase in 24-h urinary albumin excretion, 20% increase in renal glomerular volume, 18% increase in renal collagen deposition, and 8% drop of glomerular podocytes. They also displayed a dramatic (5.3-fold) increase in urinary 8-isoprostane excretion and 38% increase in renal cortex 4-hydroxynonenal adduct accumulation, indicative of enhanced systemic and local oxidative stress. Studies of potential mechanisms of oxidative injury induced by HFD feeding revealed that whereas NAD(P)H oxidase activity only tended to increase, 12/15-lipoxygenase was significantly upregulated, with ~12% increase in the enzyme protein expression and ~2-fold accumulation of 12(S)HETE, a marker of 12/15-lipoxygenase activity. PAS-positive substance accumulation, TGF- β concentrations, and glucose and sorbitol pathway intermediate concentrations, as well as CHOP, phospho-eIF2 α , and total eIF2 α expression were indistinguishable between normal and HFD-fed mice. Surprisingly, renal cortex VEGF concentrations were reduced in HFD-fed mice, compared with controls.

Conclusion: HFD feeding causes prediabetic kidney disease, potentially via oxidative stress resulting from 12/15-lipoxygenase overexpression and activation.

1063

The crosstalk between monocyte and renal mesangial cells via interaction of metalloproteinases (MMP₂) and chemokines (Fractalkine)

Y.P. Wang, Z.L. Sun, Q. Liu, Z. Li

Department of Endocrinology, Zhongda Hospital, Institute of Diabetes, Medical School, Southeast University, Nanjing, China.

Background and aims: Previous work shown that advanced glycosylation end products (AGEs) increased the expression of fractalkine (Fkn) in human renal mesangial cells (HRMCs), and decreased the expression of MMP₂, furthermore, increased the chemotaxis and adhesiveness to the human monocytes (U937). The aim of this study was to further investigate the effect of Fkn on HRMCs treated with MMP₂, and effect of MMP₂ on U937 treated with Fkn.

Materials and methods: HRMCs was incubated with MMP₂ for 24h. U937 was incubated with recombinant human Fkn for 24h. The chemotaxis and adhesiveness of HRMCs to U937 was detected with a transwell system, co-culture and fluorescent staining respectively. The expression of Fkn was analyzed by RT-PCR and western blot, and the content in the supernatant of HRMCs was analyzed by ELISA. The expression of MMP₂ was analyzed by RT-PCR and gelatin zymograph.

Results: 1. Number of U937 transmigration to HRMCs treated with MMP₂ was increased dose dependently compared to control, but the adhesion number was decreased dose dependently (Table 1). 2. The expression of Fkn in HRMCs treated with MMP₂ (0.5, 1, 2, 3, 4, 5 ng/ml) was increased dose dependently, and the content in supernatant was decreased dose dependently (Table 1). 3. The expression of MMP₂ in U937 treated with Fkn (0.3 mg/L, 0.6 mg/L) was decreased compared to control (mRNA 0.48 ± 0.08 , 0.43 ± 0.09 vs 0.68 ± 0.21 ; Protein 1.15 ± 0.18 , 1.01 ± 0.13 vs 1.37 ± 0.15 ; $p < 0.05$). The decreased expression of MMP₂ in U937 treated with supernatant of HRMCs could be inhibited by Fkn-Ab ($p < 0.05$).

Conclusion: Fkn might up-regulate MMP₂ in U937 cells through HRMCs. Meanwhile MMP₂ increased the expression and chemotaxis of Fkn in HRMCs, but decreased the adhesiveness to the human monocytes. AGEs might participate in the interaction of Fkn and MMP₂, then contribute to the development of diabetic nephropathy.

Table 1 function and expression of Fkn in HRMCs treated with MMP₂ ($\bar{x} \pm s$)

MMP2(ng/mL)	control	0.50	1.00	2.00	5.00
chemotaxis	6.55 ± 0.51	14.21 ± 0.95	23.54 ± 1.56	34.48 ± 1.47	48.52 ± 3.55
adhesiveness	4.67 ± 0.88	3.33 ± 0.33	2.67 ± 0.56	2.00 ± 0.34	1.33 ± 0.45
Fkn mRNA	0.11 ± 0.09	0.80 ± 0.10	0.91 ± 0.09	1.04 ± 0.16	1.57 ± 0.33
Fkn Protein(ng/mL)	0.22 ± 0.03	0.27 ± 0.03	0.35 ± 0.05	0.63 ± 0.04	0.68 ± 0.01
Fkn ELISA(ng/mL)	116.60 ± 3.00	100.64 ± 1.78	75.32 ± 0.97	68.17 ± 1.31	52.28 ± 1.34

Compared to the control group, all the data has significant difference ($p < 0.05$)

Hyperglycaemic E1-DN mice develop albuminuria and glomerular injury

M.E. Hyvönen^{1,2}, J. Ustinov³, T. Otonkoski^{2,3}, P.J. Miettinen^{2,3}, S. Lehtonen¹

¹Department of Pathology, ²Hospital for Children and Adolescents,

³Biomedicum Stem Cell Center, University of Helsinki, Finland.

Background and aims: The transgenic E1-DN mice express a kinase-negative epidermal growth factor receptor (EGF-R) in their pancreatic islets and are diabetic due to impaired postnatal growth of pancreatic islet β -cells. The mice are viable and survive without insulin treatment, and can be used to investigate the effects of long term exposure to hyperglycaemic environment. The aim of this study was to characterize the development of renal injury in these diabetic mice.

Materials and methods: The transgenic mice in FVB background were generated previously. E1-DN homozygous (n=13, n=9), heterozygous (n=14, n=14) and wildtype (n=17, n=12) mice were followed to the age of 20 or 40 wks. Blood glucose was measured with glucometer, and 24 hour urine samples were collected in metabolic cages, urine volume was measured and albumin concentration analyzed by ELISA. Apoptosis was detected with caspase 3 immunoperoxidase and podocyte proteins with immunofluorescence stainings.

Results: An increase in albumin excretion rate (AER) in homozygous E1-DN mice was detected at the age of 10 wks when compared to wt mice. (AER 330 μ g/24h vs. 135 μ g/24h, $p < 0.01$) At 20 wks the increase continued. (AER 1257 μ g/24h vs. 282 μ g/24h, $p < 0.01$) At 40 wks some of the hyperglycaemic mice developed massive proteinuria, the highest AER being 64mg/24h. Histological stainings (HE, PAS) showed glomerulosclerosis in the hyperglycaemic mice. Apoptosis of glomerular cells was detected more often in homozygous E1-DN mice when compared to heterozygous and wt mice. (6.5 vs. 1 apoptotic cells / 10 glomeruli at 20 wks, and 9.8 vs. 4.4 apoptotic cells / 10 glomeruli at 40 wks, $p < 0.05$) The expression patterns of several podocyte proteins (nephrin, CD2AP, podocin and ZO-1) were not altered.

Conclusion: Hyperglycaemic E1-DN mice develop albuminuria and glomerular injury resembling human diabetic nephropathy and can serve as a new model to study diabetic nephropathy. Increased apoptosis is identified as one mechanism contributing to glomerular injury.

High glucose differentially modulates the inhibitory effects of metformin and rapamycin on mTOR signalling

Z. Molnar¹, A.B. Millward^{1,2}, W. Tse³, S. Richardson¹, A. Demaine¹

¹Peninsula College of Medicine and Dentistry, ²Diabetes Clinical Research Centre, ³Renal Unit, Derriford Hospital, Plymouth, UK.

Background and aims: There is evidence that the activation of the mTOR pathway plays an important role in diabetic nephropathy. According to clinical studies in both type 1 and type 2 diabetes, longstanding hyperglycaemia is the primary cause of diabetic nephropathy. However, the molecular mechanism of high glucose-induced mTOR activation is poorly understood. This study investigated the effects of mTOR inhibitors, metformin and rapamycin, on proliferation, cell size, and mTOR pathway activation induced by excess D-glucose and L-leucine.

Materials and methods: HEK293 cells were exposed to D-glucose (30 mM) and L-leucine (10 mM), in the presence and absence of metformin (8 mM) and rapamycin (100 nM). Cell size and proliferation were measured by flow cytometry. The activation status of the mTOR signalling pathway was determined by immunoblotting. Viability was determined by standard metabolic assays and microscopy. Data were obtained from at least three independent experiments. Statistical significance was determined at $P < 0.05$; ANOVA.

Results: L-leucine and D-glucose increased cell size (100 ± 2.8 to 114 ± 2.8 %, $P<.01$ and 100 ± 1.5 to 122.2 ± 6.7 %, $P<.05$ respectively). Both metformin and rapamycin decreased cell size in L-leucine- (114 ± 2.8 to 64.7 ± 2.9 and 59.5 ± 3.2 %, $P<.001$) and D-glucose-treated cells (122.2 ± 6.7 to 102.5 ± 5.8 and 97.7 ± 4.4 %, $P<.05$). Relative to controls metformin and rapamycin increased the G0/G1 phase of the cell cycle (55 ± 0.8 to 66.2 ± 0.5 and 61.7 ± 0.5 % respectively, $P<.01$). D-glucose pre-treatment abrogated the inhibitory effect of metformin on cell cycling but had no effect on cell cycle inhibition by rapamycin (57.7 ± 0.5 , $P>0.05$ and 62 ± 1.6 , $P<.01$ respectively). These differential effects of metformin and rapamycin on cell cycling were reflected in the activation level of mTOR assessed by immunoblotting.

Conclusions: Our results suggest that high glucose-mediated cell size increase is sensitive to inhibition by both metformin and rapamycin. However, high glucose differentially affected metformin- and rapamycin-induced cell cycle arrest and mTOR inhibition. Our findings may lead to novel insights into the mechanisms of glucose-mediated cellular hypertrophy and the role of mTOR signalling in diabetic nephropathy.

R3h-domain containing like protein is a novel regulator of glomerular basement membrane

I. Takahiro¹, M. Takemoto², Y. Akimoto³, K. Yan⁴, C. Betsholtz⁵, K. Tryggvason⁵, Y. Koutaro¹;

¹Department of Clinical Cell Biology and Medicine, Chiba University Graduate School of Medicine, ²Division of Diabetes, Metabolism and Endocrinology, Chiba University Hospital, Japan, ³Division of Microscopic Anatomy, Department of Anatomy, Kyorin University School of Medicine, ⁴Department of Pediatrics, Kyorin University School of Medicine, Tokyo, Japan, ⁵Department of Medical Biochemistry and Biophysics, Division of Matrix Biology, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Recent discoveries of podocyte expressed genes have dramatically increased our knowledge of the molecular mechanism of glomerular filter of the kidney. In order to increase our knowledge about glomerular functions, we have previously identified >300 glomerulus-enriched transcripts through large-scale sequencing and microarray profiling of the mouse glomerular transcriptome. One of the podocyte-specific transcripts identified was R3h-domain containing like (R3hdm1). The aim of this study is to analyze the functions of R3hdm1 both *in vivo* and *in vitro*.

Materials and methods: The expression patterns of R3hdm1 mRNA as well as protein were examined by RT-PCR and by the immunohistochemistry using anti R3hdm1 specific antibody. The R3hdm1 knockout mice were created in order to know the function of R3hdm1 *in vivo*.

Results: R3hdm1 was exclusively podocyte's specific, since we could not detect R3hdm1 transcripts other than the glomeruli analyzed by RT-PCR and its expression were increased in diabetic condition. The R3hdm1 gene encodes 253 amino acids composed of a SCP-like extracellular domain which has been proposed to be a Ca chelating serine protease. However function of this protein in mammals is unknown. Anti Rh3dml specific antibody localized R3hdm1 protein to peri-nuclear and/or in the nucleus. Light microscopic analysis revealed that the R3hdm1 null mice had no observable glomerular developmental defects. However, an electron microscopic study revealed thickening of the glomerular basement membrane (GBM) and effacement of the podocyte foot processes which mimicked the diabetic glomerulosclerosis. When they are induced diabetes by the injection of streptozotocin, R3hdm1 null mice produced more albuminuria and decreased renal functions than the wild type controls.

Conclusion: We identified R3hdm1 as a novel podocyte's specific gene which might have a role in the development of diabetic glomerular disease.

Dietary restriction-induced Sirt1 activation improves diabetic nephropathy through anti-inflammatory action and autophagy in diabetic wistar fatty rats

D. Koya, M. Kitada, K. Kanasaaki;
Diabetes & Endocrinology, Kanazawa Medical University, Kahokugun, Ishikawa, Japan.

Background and aims: Dietary restriction (DR) or the activation of Sirt1 induced by DR exerts anti-inflammatory effect and regulates autophagy, lead-

ing to the life expansion. The micro-inflammation has been implicated in the initiation and progression of diabetic nephropathy, and it is also shown that the regulation of autophagy associated with Sirt1 is impaired in the aging kidney. However the effects of DR on nephropathy of type 2 diabetes remains elusive. The aim of this study is to investigate whether DR exerts the reno-protective effects in Wistar fatty rats, a model of type 2 diabetes.

Materials and methods: Wistar fatty rats were treated with DR (40% restriction) for 24 weeks. We measured urinary albumin excretion (UAE), creatinine clearance (Ccr), histological changes including Periodic acid-Schiff staining (PAS) and Masson-Trichrome staining and immunohistochemistry for ED-1, a marker of macrophage. mRNA expression of MCP-1, VCAM-1, ICAM-1, TGF- β 1, fibronectin and collagen IV by real-time PCR, and acetylated-NF- κ B (p65) and Sirt1 protein expression by western blotting were also estimated in the renal cortex. In addition, autophagy was assessed by western blotting of p62/sequestosome 1 (SQSTM1), a marker for *in vivo* damaged autophagy, and electron microscopic observation of mitochondrial morphological change. Blood glucose, glycated-Hb and plasma lipid profiles were also measured.

Results: DR significantly reduced UAE and attenuated renal histological changes in Wistar fatty rats. The mRNA expression of inflammation- and fibrosis-related genes were almost completely improved to the control levels of non diabetic Wistar lean rats. The increase of acetylated-NF- κ B and p62/SQSTM1 were observed in Wistar fatty rats. We also revealed that the Sirt1 expression was decreased and mitochondria morphology was altered, resulted in swelling and disintegration of cristae in the renal cortex of Wistar fatty rats. DR ameliorated the alterations of NF- κ B, p62/SQSTM1, Sirt1 expression, and mitochondrial changes seen in the kidney of Wistar fatty rats. The increased blood glucose, glycated-Hb, and abnormal lipid profiles in Wistar fatty rats were partially improved by the treatment with DR.

Conclusion: DR could exert anti-inflammatory effects and improve the regulation of autophagy through restored Sirt1 activation in the kidney of Wistar fatty rats, resulting in the amelioration of renal injuries in type 2 diabetic kidney.

Dietary restriction retards ageing and diabetes-related kidney injury

T.M.M. Louro, C.M. Sena, R.M. Seica;
Institute Physiology and IBILI, Faculty of Medicine, Coimbra, Portugal.

Background and aims: Aging is a biological process and is associated with various metabolic disorders, including type 2 diabetes. The incidence of type 2 diabetes has risen considerably in the past 2 decades and diabetic nephropathy is one of the most important microvascular complications observed in diabetes. It is known that dietary restriction has an important role in preventing age-related diseases. The main purpose of the study was to analyze the effect of dietary restriction on kidney function related with aging and type 2 diabetes.

Materials and methods: Male control Wistar and diabetic Goto-Kakizaki rats, with 12 months of age, were divided in four groups: two groups of Wistar (W) and GK rats (GK) fed ad libitum and two groups of Wistar (WDR) and GK rats (GKDR) with dietary restriction up to 35% during 4 months. We analyzed the metabolic profile, pro-inflammatory [tumor necrosis factor- α (TNF- α), interleukin (IL)-6, interleukin (IL)-1 β] and fibrotic [transforming growth factor (TGF)- β 1] markers, AMP-activated protein kinase (AMPK) and sirtuin-1 (SIRT1) in all groups by ELISA and Western Blot techniques.

Results: Dietary restriction significantly reduced (22%, $p<0.001$) body weight in GK rats, and glycaemia 2h after glucose load (20% and 27%, $p<0.01$) and HbA1c (6%, $p<0.05$; 16%, $p<0.001$) in normal and diabetic rats. Dietary restriction significantly improved triglycerides (27%, $p<0.05$; 60%, $p<0.001$) and free fatty acids (FFAs) (71%, $p<0.001$; 45%, $p<0.05$) in normal and diabetic rats. Furthermore, dietary restriction reduced the levels of all pro-inflammatory and pro-fibrotic markers in Wistar (TNF- α 25%, $p<0.05$; IL-1 β 25%, $p<0.01$; IL-6 31%, $p<0.01$; TGF- β 1 5%, $p<0.05$) and GK rats (TNF- α 50%, $p<0.01$; IL-1 β 33%, $p<0.01$; IL-6 32.5, $p<0.05$ and TGF- β 1 5%, $p<0.05$). Noteworthy, the ratio phospho-AMPK/AMPK (38% and 33%) and the levels of SIRT1 (24% and 21%) in normal and diabetic rats were significantly increased by dietary restriction ($p<0.05$).

Conclusion: The present study suggests that dietary restriction improves the metabolic profile and kidney function by a mechanism that apparently involves SIRT1 and AMPK in aged normal W and diabetic type 2 GK rats.

K-21299, a novel angiotensin II receptor blocker and selective PPAR γ agonist, is more effective than telmisartan in improving diabetic nephropathy in ZDF rats

R. Sekimoto, R. Ishida, H. Aoki, T. Miura, S. Tanabe;

Tokyo New Drug Research Laboratories, Pharmaceutical Division, KOWA Company, LTD., Japan.

Background and aims: Angiotensin II (AII) receptor blockers (ARBs) have been shown to be of benefit for the treatment of diabetic nephropathy. Recently, peroxisome proliferator-activated receptor- γ (PPAR γ) agonists have also been demonstrated to slow the progression of diabetic nephropathy. Telmisartan is a unique ARB with a PPAR γ agonistic action, which may contribute to the beneficial pleiotropic effects. We have developed a novel ARB, K-21299, which has strong PPAR γ agonistic action compared with telmisartan. This study was performed to evaluate the efficacy of K-21299 for use in the treatment of diabetic nephropathy.

Materials and methods: Zucker diabetic fatty (ZDF) rats were orally administered K-21299 (1, 3, and 10 mg/kg/day), telmisartan (3 mg/kg/day) or vehicle alone for 15 weeks. Urine and blood samples were collected for measurement of urinary total protein (UTP) excretion and for biochemical analysis, respectively. BP was measured with the tail cuff method. Fifteen weeks after administration, the kidneys were excised for histological assessment and liver samples were collected for gene expression analysis.

Results: Progressive proteinuria was significantly suppressed by K-21299 in a dose-dependent manner, whereas the reduction of BP by K-21299 was similar regardless of the dose. K-21299 induced a more marked decrease in UTP than the same dose of telmisartan. Moreover, the histological glomerular damage was also ameliorated by K-21299. The results of biochemical analyses indicated that K-21299 decreased plasma triglyceride, total cholesterol, non-esterified fatty acid, LDL-cholesterol and uric acid levels, but not plasma glucose levels. In addition, sterol regulatory element binding protein 1c mRNA and the expression levels of genes associated with fatty acid synthesis were down-regulated by K-21299 in the liver. On the other hand, telmisartan decreased only plasma total cholesterol levels, but did not affect the other blood biochemical parameters.

Conclusion: K-21299 markedly ameliorated progressive diabetic nephropathy in ZDF rats. Furthermore, the renal protective effect of K-21299 was independent of the antihypertensive effect, possibly due to its potentiated PPAR γ agonistic action compared with telmisartan. These results suggest that K-21299 may be more beneficial than other ARBs for use in the treatment of diabetic nephropathy.

Nitric oxide bioavailability is ameliorated by green tea in experimental diabetes mellitus

A.M. Faria, A. Papadimitriou, J.M. Lopes de Faria, J.B. Lopes de Faria;
Faculty of Medical Sciences, State University of Campinas, Brazil.

Background and aims: In diabetes mellitus (DM) nitric oxide (NO) deficiency contributes to diabetic nephropathy (DN). In these settings, NO deficiency is the result of reduced NO production by uncoupled endothelial nitric oxide synthase (eNOS), and increased consumption, secondary to ligation of NO with superoxide (O_2^-), forming peroxynitrite. Tetrahydrobiopterin (BH_4) levels are essential to maintain the eNOS coupled. Uncoupled eNOS produces O_2^- instead NO, contributing to oxidative stress. It has been demonstrated that in experimental DM green tea (GT; *Camellia sinensis*) ameliorates DN by reducing oxidative stress. However the effect of GT in NO bioavailability and synthesis in experimental DM is unknown. The aim of the present study was to investigate the potential of GT to ameliorate NO bioavailability in diabetic conditions.

Material and methods: Twelve-week-old spontaneously hypertensive rats (SHR) were rendered diabetic by intravenous injection of streptozotocin (50 mg/kg), whereas control rats received citrate buffer. Diabetic SHR rats were randomized to receive no treatment or treatment with daily, freshly prepared, GT (1.7g/kg body weight/day). After 12 weeks of treatment the levels of NO were determined by nitrate/nitrite. BH_4 was measured in urine and renal cortex samples using UPLC (Ultra Performance Liquid Chromatography). For *in vitro* studies, human mesangial cells (HMC) were cultured in normal glucose (NG; 5mM) and high glucose (HG; 30mM) with or without GT treatment (100ug/ml). Oxidative stress was assessed by DCF-DA and NADPH oxidase induced O_2^- generation by lucigenin.

Results: The systolic blood pressure did not differ between groups of the study. However, body weight was less ($p < 0.0001$) and glycemia was greater in diabetic SHR rats (treated or not with GT) than in nondiabetic rats ($p < 0.0001$). In diabetic animals, there was a reduction in NO bioavailability, which was reversed with GT. There was no difference in the renal eNOS expression between the groups, but the expression of p-Thr497eNOS, an indication of inactivation of eNOS, was increased in diabetic animals and decreased by GT treatment. Total biopterin, BH_4 and oxidation rate of BH_4 in urine and renal cortex were significantly reduced ($p < 0.0001$) in diabetic rats and reversed by GT ($p < 0.05$). In HMC, cultured under HG, there was a rise in reactive oxygen species (ROS) production ($p < 0.001$). The main source of ROS, in HMC under HG, was NADPH oxidase ($p < 0.0001$), but eNOS uncoupling also plays a key role in HG-induced oxidative stress ($p = 0.04$). Treatment of HMC with GT reversed the rise in ROS ($p < 0.001$). NO levels were reduced by HG and were restored with GT treatment. Both blockade of the biosynthesis of BH_4 and recycling of 7,8-dihydro-L-biopterin (BH_2) to BH_4 increased ROS production in both NG and HG conditions ($p < 0.0001$), and they were restored with GT treatment ($p < 0.001$). Addition of BH_4 to HMC exposed to HG also decreased ROS production ($p = 0.005$). However, treatment of HMC with GT plus BH_4 did not reduce ROS production compared to HMC cultured only with GT, suggesting that GT may act in synthesis or recycling of BH_4 .

Conclusion: In summary, green tea increased NO bioavailability by restoration of BH_4 production, coupling eNOS and reducing oxidative stress, abnormalities that are involved in the pathogenesis of diabetic nephropathy.

Advanced glycation end products increase human mesangial foam cell formation by SCAP dysfunction

Y. Yuan¹, X. Ruan², J. Moorhead², Z. Sun¹;

¹Department of Endocrinology, ZhongDa Hospital, SouthEast University, Nanjing, China, ²Centre for Nephrology, University College London (UCL) Medical School, UK.

Background and aims: Diabetic nephropathy caused by advanced glycation end products (AGEs) is associated with lipid accumulation in glomeruli. This study was designed to investigate whether N^ε-(carboxymethyl) lysine (CML, a member of the AGEs family) increases lipid accumulation in human mesangial cells (HMCs) via the LDL receptor pathway by increasing SREBP cleavage-activating protein (SCAP) transcription and its glycosylation in the Golgi apparatus.

Materials and methods: Intracellular cholesterol content was assessed by Oil Red O staining and cholesterol assay in HMCs treated with CML. mRNA and protein levels of molecules controlling cholesterol homeostasis were examined in the treated cells using real-time quantitative RT-PCR and western blotting, respectively. The activity of Golgi processing enzymes was determined using enzyme-based methods and the translocation of SCAP from the endoplasmic reticulum (ER) to the Golgi was detected by confocal microscopy.

Results: CML increased cholesterol accumulation in HMCs. Exposure to CML increased expression and abnormal translocation of SCAP from ER to Golgi even in the presence of a high concentration of LDL. The increased SCAP translocation carried more transcription factor SREBP-2 to the Golgi for activation by proteolytic cleavage, enhancing transcription of HMGCoA reductase and the LDL receptor. Furthermore, CML enhanced SCAP glycosylation by upregulating Golgi mannosidase activity. This prolonged the half-life and enhanced recycling of SCAP between the ER and the Golgi. The effects of CML were blocked by inhibitors of Golgi mannosidases.

Conclusion: AGEs (CML) increased lipid synthesis and uptake, thereby causing foam cell formation via increasing transcription and protein glycosylation of SCAP by Golgi enzymes in HMCs. These data imply that inhibitors of Golgi processing enzymes might have a potential renal protective role in prevention of mesangial foam cell formation.

Higher serum high-mobility group box 1 levels are cross-sectionally associated with micro- and macroalbuminuria, but not with cardiovascular disease in type 1 diabetes: the EURODIAB PCS

I. Ferreira¹, J.W.M. Nin², C.G. Schalkwijk^{2,3}, M.H. Prins^{4,5}, N. Chaturvedi⁶, J.H. Fuller⁷, C.D.A. Stehouwer^{2,3};

¹Departments of Internal Medicine and Clinical Epidemiology & Medical Technology Assessment, Maastricht University Medical Centre, ²Internal Medicine, Maastricht University Medical Centre, ³Cardiovascular Research Institute Maastricht (CARIM), ⁴Clinical Epidemiology and Medical Technology Assessment, Maastricht University Medical Centre, ⁵Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands, ⁶International Centre for Circulatory Health, National Heart and Lung Institute, Imperial College London, ⁷Epidemiology and Public Health, Royal Free and University College London Medical School, UK.

Background and aims: High-mobility group box 1 (HMGB1) is a pro-inflammatory cytokine that may contribute to the pathogenesis of vascular complications commonly observed in diabetes. In another study we found that plasma HMGB1 was associated with incident cardiovascular disease (CVD) in patients with type 1 diabetes. Whether HMGB1 is also associated with microvascular complications is unclear. Therefore, we investigated whether serum HMGB1 is associated with: (1) the presence and severity of nephropathy and retinopathy, and prevalent CVD in type 1 diabetes; and (2) the potential mediating roles of markers of low-grade inflammation (LGI) and endothelial dysfunction (ED), and pulse pressure (PP, a marker of arterial stiffness) therein.

Materials and methods: We included 463 patients (226 women; mean age 40±10 yrs) with type 1 diabetes from the EURODIAB Prospective Complica-

tions Study. We used linear and binary or multinomial logistic regression analyses adjusted for age, sex, HbA_{1c}, duration of diabetes, body mass index, total cholesterol, triacylglycerols, mean arterial pressure, antihypertensive treatment, smoking, and presence of CVD, albuminuria and/or retinopathy as appropriate.

Results: Serum Ln-HMGB1 levels were positively associated with LGI and ED [standardised regression coefficient $\beta=0.07$ (95% CI: 0.02 to 0.12) and $\beta=0.08$ (0.02 to 0.15), respectively], but not with PP. Higher serum Ln-HMGB1 levels (per unit increase) were associated with greater odds of micro- and macroalbuminuria: OR=1.23 (0.90 to 1.69) and OR=1.63 (1.18 to 2.24), respectively. Further adjustments for markers of LGI or ED did not attenuate these associations. Serum Ln-HMGB1 levels were not associated with estimated glomerular filtration rate by Cockcroft-Gault formula [eGFR, $\beta=-0.04$ (-0.11 to 0.03)], background and proliferative retinopathy [OR=0.93 (0.69 to 1.25) and OR=0.89 (0.64 to 1.25), respectively] or CVD [OR=0.87 (0.67 to 1.12)], however.

Conclusion: This study shows that in individuals with type 1 diabetes higher serum HMGB1 levels are associated with greater prevalence and severity of albuminuria, though not with eGFR, retinopathy, and CVD. However, this finding of no association between serum HMGB1 levels and prevalent CVD together with the positive association between plasma HMGB1 and incident CVD observed in our other study may suggest that serum levels and plasma levels of HMGB1 do not represent the same pool of HMGB1. Further studies are needed to clarify both the interrelationship between serum and plasma levels of HMGB1, and their roles, if any, in the pathogenesis of vascular complications in type 1 diabetes.

Diabetic nephropathy in T1DM is associated with an altered expression of genes regulating TGF-beta signalling and fibrosis, apoptosis and cell cycle. Studies in primary cultures of human fibroblasts

E. Iori, R. Million, L. Lenzini, L. Puricelli, G. Rossi, P. Tessari;

Clinical and Experimental Medicine, University of Padova, Italy.

Background and aims: Diabetic nephropathy (DN) has a genetic component, still largely unknown. The search for genetic markers in predisposed individuals can help in the identification of individuals at risk, as well as in the understanding of the underlying patho-physiological processes leading to DN. To these purposes, we have determined the whole transcriptome in cultured human fibroblasts after 8 passages in culture, derived from T1DM patients with a long disease duration (>15 years), either with established DN (DN+, n = 5), or without DN (DN-, n = 5), as well as in healthy controls (n = 5), by a microarray technique.

Materials and methods: All the subjects were matched for age, sex, and BMI, and the two groups of T1DM subjects also for metabolic control (HbA_{1c} in DN+ : 10.5±1.3%; DN- : 9.3±0.8%), as well as for diabetes duration (DN+ : 21.8±4.5 yrs; DN- : 22.8±3.2 yrs). The comparison between groups was performed by ANOVA, with a level of significance set at p<0.01. Furthermore, over- and under-expressed genes were selected using a cut-off fold change of >3.

Results: With respect to control subjects, the largest differences as regards both the number of genes and the magnitude of the differences, were found in the cultured fibroblasts of the T1DM patients with DN. 197 genes were under-expressed, whereas 89 were over-expressed. The genes showing the largest differences between T1DM patients and controls were ranked according to the magnitude of change. Thereafter, they were grouped also on the basis of their function. The main alterations in expression were found in genes regulating TGF-beta signalling and fibrogenesis, (n = 4, among them thrombospondin-1), apoptosis (n = 13, among them interleukin7, coagulation factor II receptor) and cell cycle (n = 36, among them the cyclin-dependent kinases CDC45L and CDKN2C).

Conclusion: We report a number of differences in gene expression in cultured fibroblasts of T1DM subjects with vs. without DN, as well as with respect to control subjects. Since the microarray study was performed in cells kept in culture for many passages, it is unlikely that preceding, in vivo environmental factors accounted for the differences observed. Furthermore, the degree of metabolic control, based on HbA_{1c} value, was similar between two diabetic groups. Therefore, these findings can help both in the identification of individuals genetically predisposed to DN, as well as in the understanding of the patho-physiological mechanisms leading to DN.

Incretin effect and gastrointestinal-mediated glucose disposal in patients with end-stage renal disease and normal or impaired glucose tolerance

T. Idorn¹, F.K. Knop², I. Eidemak¹, J.J. Holst³, M. Hornum¹, B. Feldt-Rasmussen¹;

¹Department of Nephrology, Rigshospitalet, University of Copenhagen,

²Department of Internal Medicine, Gentofte Hospital, Copenhagen,

³Department of Biomedical Sciences, the Panum Institute, University of Copenhagen, Denmark.

Background and aims: Type 2 diabetes mellitus (T2DM) is characterized by a severely impaired incretin effect. Patients with T2DM and non-diabetic patients with end-stage renal disease (ESRD) share several pathophysiological traits: insulin resistance, hyperinsulinaemia and impaired beta cell function. We aimed to determine the incretin effect in non-diabetic patients with ESRD treated with chronic maintenance haemodialysis.

Materials and methods: The incretin effect was measured in 10 patients with ESRD and normal glucose tolerance (NGT), 10 patients with ESRD and impaired glucose tolerance (IGT) and 11 healthy control subjects (CTRL), using 3-hour 75 g-oral glucose tolerance test (OGTT) and isoglycaemic intravenous glucose infusion (IIGI) on separate days. Gastrointestinal-mediated glucose disposal (GIGD) based on glucose amounts utilized ($100 \times (\text{glucose}_{\text{OGTT}} - \text{glucose}_{\text{IIGI}}) / \text{glucose}_{\text{OGTT}}$) and incretin effects based on area under curve (AUC) for insulin ($100 \times (\text{AUC}_{\text{OGTT}} - \text{AUC}_{\text{IIGI}}) / \text{AUC}_{\text{OGTT}}$) were calculated.

Results: All groups were matched by age, body mass index and gender. The amount of glucose needed to obtain isoglycaemia during IIGI was significantly ($p < 0.02$) greater in both of the uraemic groups (46 ± 17 g (NGT) and 52 ± 8 g (IGT), $p = 0.4$ between groups) compared to CTRLs (31 ± 6 g). Correspondingly, GIGD was found to be significantly ($p < 0.02$) diminished in the uraemic groups ($38 \pm 7\%$ (NGT) and $31 \pm 3\%$ (IGT), $p = 0.4$ between groups) compared to the CTRL group ($59 \pm 3\%$) (Fig. 1). Incretin effects amounted to $64 \pm 16\%$ (CTRL), $54 \pm 15\%$ (NGT) and $38 \pm 26\%$ (IGT), respectively, with significant difference between CTRLs and IGTs ($p = 0.01$).

Conclusion: ESRD patients with NGT or IGT are characterised by reduced GIGD compared to subjects with NGT and normal kidney function and the incretin effect is significantly impaired in ESRD patients with IGT.

Evaluation of bone mineral density in long-standing type 1 diabetic patients with or without diabetic nephropathy

M. Lajer¹, S. Theilade¹, C. Joergensen¹, F. Persson¹, G. Andrésdóttir¹, H. Reinhard¹, H.-H. Parving^{2,3}, L. Tarnow¹, P. Rossing¹;

¹Steno Diabetes Center, Gentofte, ²Rigshospitalet, Dep. Medical

Endocrinology, Copenhagen, ³Faculty of Health Science, Aarhus, Denmark.

Background and aims: Patients with chronic kidney disease including diabetic nephropathy have been suggested to have a lower bone mineral density (BMD). The aim of the study was to measure bone mineral density (BMD)

and evaluate the prevalence of osteoporosis in long-standing type 1 diabetic patients with or without overt diabetic nephropathy.

Materials and methods: Cross sectional evaluation of a prospectively followed cohort of 293 long-standing, type 1 diabetic patients. From 1/2-2011 to 31/3-2011, 115 patients with diabetic nephropathy (54% men; age [mean±SD] 54 ± 9 years, 42 ± 8 years of diabetes, duration of nephropathy 22 ± 6 years) and 178 patients with persistent normoalbuminuria (49% men, age 59 ± 10 years, 41 ± 10 years of diabetes) were included. BMD (g/cm^2) in femoral neck, total femoral bone and lumbar spine was measured by dual energy x-ray absorptiometry (DXA), (Hologic, Discovery A). Osteopenia and Osteoporosis were defined by any sex matched T-score ranging from -2.5 to -1.0 and < -2.5 , respectively. The difference between the measured BMD and age-sex matched average defines the Z-score. GFR was measured by ^{51}Cr -EDTA plasma clearance in patients with nephropathy.

Results: Among patients with diabetic nephropathy, 58 (50%) and 31 (27%) had T-scores corresponding to osteopenia and osteoporosis, respectively compared to 106 (60%) and 22 (12%) of the normoalbuminuric patients; $p = 0.006$. Among male patients with nephropathy, the prevalence of osteoporosis was 37% vs. 9% with normoalbuminuria ($p < 0.001$), whereas no difference was seen among women. Similarly, men with nephropathy had significantly lower age-sex matched spinal, femoral neck and total femoral bone Z-scores compared to normoalbuminuric patients; $p \leq 0.002$. Among women, there was no statistically difference. Finally, among patients with diabetic nephropathy, baseline GFR levels did not differ between men and women (94 ± 29 vs. 95 ± 30 ; $p = 0.92$), respectively but correlated positively with femoral neck and total femoral BMD ($r = 0.36$ and $r = 0.38$; $p < 0.001$, respectively). Collection of data regarding the prevalence of diagnosis/treatment of osteoporosis and history of fractures is ongoing.

Conclusion: The risk of osteoporosis was highest among male patients with type 1 diabetes and long-standing diabetic nephropathy and femoral BMD correlated with renal function. Hence screening, prevention and treatment of osteoporosis in patients with impaired renal function should be considered.

Serum bilirubin levels and the changes in kidney function in type 2 diabetic patients

K. Toya, T. Babazono, M. Mugishima, N. Yoshida, I. Nyumura, R. Bouchi, K. Hanai, N. Tanaka, Y. Uchigata, Y. Iwamoto;
Diabetes Center, Tokyo Women's Medical University, Japan.

Background and aims: Oxidative stress has been implicated in the pathogenesis of diabetic vascular complications, including diabetic kidney disease (DKD). Bilirubin is a potent antioxidant that effectively scavenges peroxyl radicals and suppresses the oxidation of lipids and lipoproteins. In patients with type 2 diabetes mellitus (T2DM), serum bilirubin levels were shown to be positively correlated with estimated glomerular filtration rate (eGFR). Another report documented decreased serum bilirubin levels to be associated with reduced eGFR only in women. However, these studies were limited by cross-sectional design. We therefore conducted this longitudinal study to clarify the association between serum bilirubin levels and the deterioration of kidney function in T2DM patients. Gender differences in the association were also determined.

Materials and methods: This was a single institutional observational cohort study, including Japanese adult T2DM patients with normoalbuminuria, defined as urinary albumin-to-creatinine ratio (ACR) < 30 mg/g. Subjects with malignant disease, liver cirrhosis, hematologic disease, and those with serum bilirubin ≥ 1.2 mg/dL were excluded. Patients were followed up for at least 2 years. The primary outcome measurement was the rate of change in eGFR. For statistical analyses, multiple regression analysis and analysis of covariance (ANCOVA) were conducted.

Results: Overall, 1,441 patients, 599 women and 842 men, with a mean (\pm SD) age of 59 ± 12 years, were studied. The mean follow-up period was 5.4 ± 1.1 years (range: 2.0–7.1) years and the mean annual rate of change in eGFR in the entire cohort was -0.76 ± 1.96 mL/min/1.73 m^2 /year. A significant interaction between serum bilirubin levels and gender on the primary outcome was detected (p interaction = 0.045); therefore, women and men were analyzed separately. In women, the univariate regression analysis showed a significant correlation between serum bilirubin levels and the rate of change in eGFR ($r_s = 0.080$, $p = 0.049$), indicating that higher serum bilirubin levels were associated with slower decline in eGFR. In the multivariate regression analysis adjusted for other clinical factors, serum bilirubin level remained as a statistically significant variable associated with the rate of change in eGFR (standardized parameter estimate = 0.100, $p = 0.013$). In men, there was no significant association between serum bilirubin levels and the rate of change

in eGFR in either univariate or multivariate analysis. Next, we classified subjects into gender-specific tertiles according to bilirubin levels to clarify the effect of bilirubin treating as a categorical variable. In women, the adjusted rate of change in eGFR in the third bilirubin tertile (-0.36 ± 0.14 mL/min/1.73 m²/year) was significantly slower than in the first tertile group (-0.84 ± 0.16 mL/min/1.73 m²/year, $p = 0.027$) and the second tertile (-0.79 ± 0.12 mL/min/1.73 m²/year, $p = 0.022$). In men, there were no significant differences in the adjusted rate of change in eGFR among the 3 tertiles.

Conclusion: Higher levels of serum bilirubin may be predictive of slower deterioration of kidney function in diabetic women but not in men.

CKD categories by KDIGO and the progression rate in GFR, albuminuria and cardiovascular disease in type 2 diabetes without prevalent cardiovascular disease: prospective cohort study

H. Yokoyama¹, M. Matsushima², K. Kawai³, M. Oishi⁴, K. Hirao⁵, H. Sugimoto⁶, H. Sone⁷, S.-I. Araki⁸, A. Kashiwagi⁸, JDDM Study Group; ¹Internal Medicine, Jiyugaoka Clinic, Obihiro, ²Internal Medicine, Jikei University School of Medicine, Tokyo, ³Internal Medicine, KawaiClinic, Tsukuba, ⁴Internal Medicine, OishiClinic, Kyoto, ⁵Internal Medicine, HEC science Clinic, Yokohama, ⁶Internal Medicine, sugimoto Clinic, Kitakyusyu, ⁷Internal Medicine, University of Tsukuba, Mito, ⁸Department of Medicine, Shiga University of Medical Science, Otsu, Japan.

Background and aims: The continuum of development, progression and complications of diabetic renal disease is not fully understood. The aim of this study was to investigate the risk in terms of the stage progression rate in albuminuria and eGFR and the cardiovascular occurrence rate based on the categories by albuminuria and eGFR through a large nationwide prospective cohort study in Japan.

Materials and methods: A prospective study was performed in primary care settings at multiple clinics nationwide. Participants were 2,984 individuals with type 2 diabetes without prevalent cardiovascular disease. CKD was defined according to the KDIGO classification, and stage 3 CKD was further classified into stage 3N (with normoalbuminuria) and 3M (with micro/macrolbuminuria).

Results: During a median follow-up of 3.8 yr, the incidence rate of cardiovascular event was 8.3 (95% CI 6.7–9.9) per 1,000 person years. 1) Compared to No CKD as a reference group, individuals with stage 2 and stage 3M CKD had a significantly increased risk of adverse cardiovascular outcomes ($p < 0.05$, $p < 0.01$, respectively). 2) Individuals with stage 1 and stage 3N did not reveal any significant risk of adverse cardiovascular outcomes, while those with stage 1 had a high rate of progression to stage 2 (40% per 4-year). 3) Progression rate in albuminuria stage was similar between No CKD and Stage 3N (10% and 12% per 4-year, respectively). Progression rate in GFR stage was more than three-fold higher in subjects with albuminuria (Stage 2 and 3M, 17% and 10% per 4-year, respectively) than in those with normoalbuminuria (No CKD and 3N, 5% and 2% per 4-year, respectively). 4) Among subjects with No CKD, those of whom albuminuria stage progressed during follow-up (transited from normoalbuminuria to albuminuria) showed a significantly increased risk of adverse cardiovascular outcomes ($p < 0.01$), whereas those of whom GFR stage progressed did not.

Conclusion: This prospective cohort study of Japanese type 2 diabetes indicates that development of microalbuminuria plays a crucial role as an initial

step to the occurrence of renal function loss and cardiovascular disease, while further follow-up is ongoing.

Cardiovascular risk factors and complications associated with impaired renal function and albuminuria in insulin-treated type 2 diabetes

K. Doggen¹, A.J.L. Scheen², P. Van Crombrugge³, F. Nobels³, N. Debacker¹, V. Van Casteren¹, C. Mathieu⁴;

¹Scientific Institute of Public Health, Brussels, ²CHU Sart Tilman, Liège,

³O.L. Vrouwziekenhuis, Aalst, ⁴UZ Gasthuisberg, Leuven, Belgium.

Background and aims: Albuminuria (AU) and reduced estimated GFR (ReGFR) predict cardiovascular (CV) events in type 2 diabetes. In this study, we investigated the association of AU and ReGFR with CV risk factor control, treatment and prevalent complications in longstanding insulin-treated type 2 diabetic patients.

Materials and methods: Cross-sectional study among 5100 insulin-treated (≥ 2 injections/day) type 2 diabetic patients visiting Belgian secondary care diabetes centres in 2009. AU was defined as ≥ 20 µg/min, ≥ 30 mg/24 h, ≥ 30 mg/g creatinine, or ≥ 20 mg/L. ReGFR was defined as eGFR < 60 mL/min/1.73 m².

Results: At least 80% of patients received antihypertensive drugs and 70% received lipid-lowering drugs (see table). Number of patients treated with antihypertensive drugs increased as AU, ReGFR or both were present. By contrast, lipid-lowering treatment was associated only with ReGFR, and not with AU. The higher rate of lipid-lowering treatment among ReGFR patients was associated with higher use of fibrates (9.3% vs. 6.5% in patients without ReGFR). AU patients, with or without ReGFR, had higher systolic and diastolic blood pressure, and higher total and LDL cholesterol (LDL-C) than patients with ReGFR alone or with neither AU nor ReGFR while HDL-C and triglycerides (TG) were increasingly worse in patients with AU alone, ReGFR alone and patients with both. HbA1c was significantly increased in AU patients without ReGFR. ReGFR patients, with or without AU, were older and had longer diabetes duration than patients with AU only and patients with neither AU nor ReGFR. Both AU and ReGFR were associated with higher prevalence of retinopathy and a history of macrovascular disease (including coronary heart disease, peripheral artery disease and stroke). However, “isolated” AU and ReGFR were associated with similar prevalence of macrovascular disease.

Conclusion: CV risk factor control, treatment and complications were quite different among type 2 diabetic patients with either AU, ReGFR or both. Of note, ReGFR patients without AU had a high burden of macrovascular disease, despite high treatment rates and moderately good risk factor control.

Clinical data stratified by presence of AU or ReGFR.

AU/ReGFR	No/No (N=2351, 46.1%)	Yes/No (N=1094, 21.5%)	No/Yes (N=812, 15.9%)	Yes/Yes (N=843, 16.5%)	All patients (N=5100)

Cardiovascular risk factors and prediction of albuminuria in patients with type 2 diabetes, a neural network analysis

M. Nakhjavani, A. Morteza, A. Esteghamati, F. Esfahanian, F. Asgarani, O. Khalilzadeh;
Endocrine Research Center, Tehran University of Medical Sciences, Islamic Republic of Iran.

Background and aims: Albuminuria is a sensitive marker of future cardiovascular events in patients with type 2 diabetes and healthy controls. Neural networks (NN) had attracted a great deal of attention for predicting outcome in biomedical researches. We aimed to assess the potential role of cardiovascular risk factors in the prediction of albuminuria in patients with T2DM, using a multilayer perception NN modeling.

Materials and methods: The study included 1162 patients with type 2 diabetes. Albuminuria was defined as urinary albumin excretion rate >30 mg/24 hour. The NN was employed for the prediction of normo/micro and macroalbuminuria. The patients were randomly classified into a: training (382/615; 62%), b: testing (169/615; 27.8%) and c: holdout (64/615; 10.2%) groups. NN uses learning algorithm to define the nonlinear mathematical transfer functions, to modify the synaptic weights of a network's processing units in an orderly fashion to attain the desired outcome prediction. Hence the model, which is extracted from the training group, is tested 3 times and the importance of each variable is checked by different weight and functions. A total of 552 out of 1162 cases were not included for NN modeling. Input variables were, age, sex, duration of diabetes, systolic blood pressure, diastolic blood pressure, Glomerular filtration rate (GFR), high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C), fasting plasma glucose, HbA1C, cholesterol and triglyceride.

Results: The study included 690 female and 472 male, aged 19-94 years. Of all the studied patients, 817/1162 (70%) had <30 mg/24 h, 203/1162 (17%) had 30-300 mg/24 h and 142/1162 (12%) had >300 mg/24 h albuminuria. Patients with albuminuria were older, had longer diabetes duration and a higher systolic blood pressure, diastolic blood pressure, HbA1C, triglyceride and a lower GFR and HDL compared to patients with normoalbuminuria. The model included 6 hidden layers and 1 bias. Percent of correct prediction was 80% in the training group, 74% in the testing group, and 77% in the holdout group. Percent of incorrect predictions were 20% in the training group, 26% in the testing group and 23% in holdout group. HDL had the greatest importance in the prediction of micro/macro albuminuria in the designed model (Figure 1). We compared patients with and without albuminuria with different cut points of HDL. Cardiovascular risk factors were the same for patients with a serum HDL higher than 40 mg/dl: either with micro/macro albuminuria and/or normoalbuminuria. All the cardiovascular risk factors were worst in patients with albuminuria and a serum HDL level lower than 40 mg/dl: compared to patients with normoalbuminuria. GFR had the second importance in prediction of albuminuria.

Conclusion: Consistent with our previous study, with a mathematics-based risk factor-outcome model, we showed the significance and importance of HDL in the prediction of albuminuria.

Angiogenin levels are elevated in patients with diabetes and microalbuminuria

C. Hoebaus¹, M. Ursli¹, J.M. Brix², R. Koppensteiner¹, G. Scherthaner², G.-H. Scherthaner¹;

¹Angiology, Medicine II, Medical University of Vienna, ²Medicine I, Rudolfstiftung Hospital, Vienna, Austria.

Background and aims: The vast increase of diabetes in the western world challenges us with macrovascular and microvascular complications of the disease. Angiogenin, a small polypeptide, is associated with various forms of cancer and a potent inducer of vascular growth. In this study we investigated angiogenin as a possible biomarker for early microangiopathy/endothelial dysfunction in patients with diabetes.

Materials and methods: We measured angiogenin in 127 patients with diabetes (70 female, mean age: 51.4±16.2 years, HbA1c: 8.1±1.7rel.%). Albuminuria (ALB) was measured in 24-hour urine collections three times. ALB was defined by a least two consistent measurements over a three-month period: 86 normo-ALB (Co), 23 micro-ALB (MiA), and 18 macro-ALB (MaA). Angiogenin and Vascular Endothelial Growth Factor (VEGF) were measured by an ELISA from R&D Systems (Minneapolis, MN), Interleukin-18 (IL-18) by an ELISA from Medical & Biological Laboratories (Naka-ku Nagoya, Japan). Data are presented as median (25., 75. percentile). Statistics included Mann-Whitney-U test, Kruskal-Wallis test, and Spearman-Rho correlation, as applicable.

Results: Angiogenin levels were significantly higher in patients with ALB (359 (263,534) vs 285 (201,348) ng/ml, p=0.004). In addition, IL-18 showed a significant increase (p=0.033) in those with ALB, whereas VEGF only showed a trend towards increase (p=0.070). Furthermore, Angiogenin was higher in patients with MiA compared to Co (p=0.03), but did not differ to MaA. The presence of retinopathy did not change angiogenin levels (p=0.898). Additionally, angiogenin levels were elevated in men (p=0.047). In spearman-rho correlation analysis angiogenin levels were significantly associated with ALB (R=0.224, p=0.013), age (R=0.235, p=0.009), HbA1c (R=0.184, p=0.046), body mass index (R=0.275, p=0.003), weight (R=0.308, p=0.001), HDL cholesterol (R=-0.305, p=0.001) and triglycerides (R=0.297, p=0.002).

Conclusion: (Vascular) growth factors might be involved in the reduced prognosis of patients with MiA and MaA. We found increased angiogenin levels in patients with diabetes and albuminuria, but no relation to retinopathy.

1081

NT-proBNP predicts progression of CKD in type 2 diabetes

K. Hamano, I. Nakadaira, J. Suzuki;

Diabetes and Endocrinology, Kantoh Rosai Hospital, Kawasaki, Japan.

Background and aims: N-terminal proBNP (NT-proBNP) is postulated as a diagnostic and prognostic biomarker of heart failure and cardiovascular mortality in type 2 diabetes as well as in general population. We recently reported that NT-proBNP could be a marker of silent myocardial ischemia in type 2 diabetes. It is also known that BNP and NT-proBNP are elevated in CKD (chronic kidney disease) reflecting reduced glomerular filtration. It is possible that an additional mechanism might be present when considering the concept of cardiorenal continuum since major target organ of BNP secreted from heart is a kidney. In the present study, we tested whether NT-proBNP elevation could be a predictor of progression of CKD in type 2 diabetes with near normal kidney function.

Materials and methods: We consecutively recruited 109 patients (male 79, age 62.7±0.9, HbA1c 8.8±0.2, Cr 0.90±0.02mg/dl) with CKD stage 1 and 2. Serum NT-proBNP measurement (Roche) and ultrasonographic echocardiogram were performed and subjects were followed up to 5 years (median 44 months). Primary endpoints were defined as 1) renal: 30% decrease of eGFR due to low baseline Cr level and relatively short observation period and 2) CVD: cardiovascular disease (CVD) event and death.

Results: NT-proBNP was well correlated with left ventricular mass index and serum Cr. Baseline NT-proBNP levels were negatively associated with eGFR. During the follow-up period, fourteen patients reached the renal endpoint and had significantly higher baseline NT-proBNP than those who maintained eGFR (169 vs. 52 pg/ml, p<0.05). Patients were stratified into 2 groups

by NT-proBNP concentrations above and below the optimal cut-off points calculated by ROC analysis. Survival curves were analyzed using the Kaplan Meier calculation, and significantly higher proportions of subjects with NT-proBNP above 120 pg/ml at baseline had progressive decline of eGFR (Log rank test: $p=0.0054$). During the follow up period, eighteen patients had new incidences of CVD or death, namely CVD events. Mean levels of NT-proBNP were 78 and 43 pg/ml for those with and without new events, and these were significantly lower than that of the subjects with past CVD history ($p<0.05$). Subjects with NT-proBNP level above 60 pg/ml had significantly higher risks of CVD and death than those below 60 pg/ml (HR 3.77, $p=0.025$).

Conclusion: Both cardiac and renal functions are reflected by minimal elevations of NT-proBNP and it also predicted not only future CVD event or death as well as CKD progression in type 2 diabetes. As CKD is a major risk factor for CVD in diabetes, NT-proBNP might be one of key molecules linking kidney with CVD and eventual mortality. It is possible to stratify diabetic patients at high risk by simple measurement of NT-proBNP which is reproducible and inexpensive.

1082

RBP4 has an early marker of renal dysfunction in diabetic patients

B. Almeida, Á. Coelho;

Day Hospital for Diabetes and Metabolic Diseases, Coimbra Hospital Center, Portugal.

Background and aims: Fat tissue is viewed as an active endocrine organ with a high metabolic activity. Adipocytes produces and secretes several adipocytokines that play an important role in the metabolic control of diabetes and obesity. Retinol binding protein type 4 (RBP4) is produced by adipocytes and macrophages.

Materials and methods: Between December of 2008 and October of 2010, 309 patients were recruited with mean age 51 ± 13.5 years. They were divided in two groups: obese nondiabetic ($n = 133$) and diabetics ($n = 177$). The patients underwent anthropometric examination, with the determination of waist circumference, BMI and fat tissue using electric bioimpedance. The serum concentration of RBP4 was measured by nephelometry. Statistical analysis was made using the software SPSS vs. 17.

Results: Diabetics had higher urea, creatinine, triglycerides, alanine aminotransferase and gamma glutamyl transpeptidase values (7.2 ± 4.7 vs. 5.6 ± 1.6 mmol / L; 77.2 ± 30 vs. 69.6 ± 18.6 mmol / L; 1.8 ± 1.1 vs. 1.5 ± 0.7 mmol / L; 44.6 ± 24.7 vs. 32.3 ± 27.8 U/L; 51.9 ± 57.7 vs. 33.9 ± 45.6 U / L, $p < 0.05$) and lower HDL-C (1.2 ± 0.4 vs. 1.6 ± 0.4 mmol / L, $p < 0.05$) in comparison with the group of obese. In both groups we found a positive correlation between BMI and body fat mass with CRP ($r = 0.294$ vs. $r = 0.381$, $r = 0.384$ vs. $r = 0.398$, $p < 0.05$). Diabetic patients had higher values of RBP4 in comparison with the group of obese patients (53.5 ± 15.9 vs. 46.9 ± 17.8 mg/dl). Positive correlations were found with the urea and creatinine in both groups ($r = 0.449$ vs. $r = 0.498$, $r = 0.444$ vs. $r = 0.62$, $p < 0.01$). Positive correlation with 24 hours proteinuria was observed in diabetic patients ($r = 0.59$, $p < 0.01$) and in obese patients there was a positive correlation with triglycerides ($r = 0.374$, $p < 0.01$). No correlations were found with the anthropometric parameters.

Conclusion: This study highlights the role of adipocytokine in the metabolic profile: RBP4 is an excellent early marker of renal dysfunction. In the future it can be used to assess microvascular complications in type 2 diabetic patients.

1083

Insulin effect on agonists and antagonists of nitric oxide synthesis in type 2 diabetes mellitus with nephropathy

P. Tessari¹, D. Cecchet¹, M. Vettore¹, C. Artusi², M. Plebani², M. Marescotti¹, M. Vedovato¹;

¹Clinical and Experimental Medicine, ²Laboratory Medicine, University of Padova, Italy.

Background and aims: The synthesis of nitric oxide (NO) is stimulated by insulin both *in vitro* and *in vivo*, and it is modulated by precursor substrates (like arginine and homoarginine), by competitive inhibitors of NO synthase (ADMA: asymmetric dimethylarginine), as well as by inhibitors of intracellular arginine transport (SDMA: symmetric dimethylarginine; and ADMA itself). In Type 2 Diabetes Mellitus (T2DM) we have previously demonstrated a reduced NO synthesis from arginine both under basal and hyperinsulinemic conditions. However, the role of ADMA, SDMA and homoarginine, on NO synthesis *in vivo*, as well as their response to hyperinsulinemia, are not known.

Materials and methods: Eight patients with T2DM and diabetic nephropathy (age: 63 ± 3 yrs; BMI: 28.9 ± 0.8 kg/m²), and ten non diabetic control subjects (age: 52 ± 6 yrs; BMI: 26.4 ± 0.8 kg/m²), all males, were studied for 180' under basal conditions and for subsequent 180' with a euglycemic, hyperinsulinemic clamp, following an iv. primed-continuous infusion of L-[¹⁵N₂-guanidino]-arginine. In the final 60' of each experimental period, under steady-state conditions, we measured the fractional synthesis rate (FSR) of NO (expressed as the sum of nitrites and nitrates, NOx), ADMA, SDMA and homoarginine concentrations, and we the search for correlations among these parameters.

Results: In the T2DM patients, with respect to controls, we found increased basal SDMA concentrations (0.60 ± 0.07 vs. 0.46 ± 0.03 μM, $p < 0.05$), reduced homoarginine concentrations (1.63 ± 0.19 vs. 2.12 ± 0.17 μM, $p < 0.06$), and a reduction of both arginine/SDMA (138 ± 25 vs. 191 ± 14 , $p < 0.03$) and arginine/ADMA ratios (145 ± 10 vs. 179 ± 9 , $p < 0.025$). In contrast, ADMA (0.51 ± 0.02 μM) and arginine concentrations (74 ± 7 μM) were similar to control values (0.48 ± 0.02 and 86 ± 5 μM, respectively). Hyperinsulinemia decreased ($p < 0.001$) ADMA, SDMA, homoarginine, and arginine concentrations, as well as both the arginine/SDMA and the arginine/ADMA ratios, in both groups. However, the differences between the groups were maintained. Inverse correlations were found between NOx FSR and ADMA ($r = -0.43$, $p < 0.01$), as well as between NOx FSR and SDMA ($r = -0.53$, $p < 0.001$). Conversely, direct correlations were found between NOx FSR and the arginine/SDMA ratio ($r = 0.51$, $p < 0.002$), but not between NOx FSR and the arginine/ADMA ratio.

Conclusions: In T2DM, SDMA concentration is increased, whereas that of homoarginine, as well as the arginine/SDMA and arginine/ADMA ratios, direct modulators of NOS activity, are reduced. Acute hyperinsulinemia affects arginine-related metabolites as well as NOS activity. SDMA, as well as the arginine/SDMA ratio, are correlated with NOx FSR. SDMA levels are more closely correlated than those of ADMA with NO synthase activity *in vivo*.

Serum concentrations and urine excretion of matrix metalloproteases (MMPs) and transforming growth factor-β (TGF-β) in patients with diabetic nephropathy

S.A. Martynov, M.V. Shestakova, A.V. Ilyin, M.I. Arbuzova, I.I. Dedov; Endocrinology Scientific Center, Moscow, Russian Federation.

Background and aims: Dysbalance between the production and degradation of extracellular matrix by MMPs, especially gelatinases (MMP-2, MMP-9) and TGF-β signalling cascades play a major role in the progression glomerular sclerosis and fibrotic lesion in diabetic nephropathy (DN). The aim of our study was to evaluate the levels of serum and urine gelatinases and TGF-β and their association with renal damage markers - albumin-to-creatinine ratio (ACR), glomerular filtration rate (GFR) and hemoglobin (Hb) in patients (pts) with DN.

Materials and methods: We investigated 40 diabetic pts (13 type 1 and 27 type 2). Their mean clinical data: age - 50.0 ± 16.4 years, diabetes duration - 17.1 ± 9.8 years, HbA_{1c} - 9.1 ± 2.3 %, Hb - 130.0 ± 20.0 g/l, GFR was calculated by MDRD formula - 75.6 ± 38.6 ml/min/1.73 m². Of these, 10 pts had normoalbuminuria (NAU), 15 pts had microalbuminuria (micro-AU), 15 pts had macroalbuminuria (macro-AU). Anemia was defined by criteria for chronic kidney disease pts and WHO classification. The prevalence of anemia was 37.4%. We measured MMP-2, MMP-9 and TGF-β in serum (MMP-2, MMP-

9_{α} , TGF- β_1) and urine (MMP-2, MMP-9, TGF- β_1) by ELISA technique. The urine values were standardized to urine creatinine ratio. Pts with GFR<15 ml/min/1.73 m² were not included.

Results: As shown in Table 1 (* $p<0.05$; ** $p<0.01$; *** $p<0.001$ between NAU pts and other groups), the levels of serum and urine MMP-2 significantly increased in accordance with elevation of albuminuria degree and had a direct correlation with ACR (MMP-2_s, $r=0.69$; $p<0.001$; MMP-2_u, $r=0.76$; $p<0.001$). No differences were observed in MMP-9_s and TGF- β_1 levels in pts with elevated proteinuria, although urine excretion of MMP-9_u was higher in macro-AU pts and also was associated with ACR ($r=0.44$; $p<0.01$); TGF- β_1 was significantly lower in NAU pts. We found correlation of with GFR MMP-2_s ($r=-0.47$; $p<0.01$) MMP-2_u GFR ($r=-0.71$; $p<0.001$) TGF- β_1 ($r=-0.51$; $p<0.05$). The pts with anemia demonstrated higher levels of MMP-2_s (342.0 ± 74.6 vs 253.9 ± 69.0 ng/ml; $p<0.01$) as a MMP-2_u (1.5 ± 2.1 vs 0.4 ± 1.1 mcg/mmol; $p<0.01$). The measured parameters significantly correlated with Hb: MMP-2_s ($r=-0.69$; $p<0.001$); MMP-2_u ($r=-0.75$; $p<0.0001$); MMP-9_u ($r=-0.40$; $p<0.05$), TGF- β_1 ($r=-0.66$; $p<0.001$). Regression analysis of the above listed clinical data showed that they are significant predictors of MMP-2_s (ACR (beta=0.44), GFR (beta=-0.46), Hb (beta=-0.66)), MMP-2_u (ACR (beta=-0.48), GFR (beta=-0.56)) and TGF- β_1 (GFR (beta=-0.43), Hb (beta=-0.55)).

Conclusion: Elevation of serum concentration of MMP-2 in albuminuric pts may presumably displays their excess production in the kidney. Increasing the urine excretion of gelatinases, especially MMP-2 and TGF- β in advanced albuminuria and their association with signs of renal failure (GFR), and anemia (Hb) could more accurately reflect development of renal interstitial fibrosis.

Serum and urine levels of MMP-2, MMP-9 and TGF- β in diabetic patients according to albuminuria

Parameters	NAU pts	Micro-AU pts	Macro-AU pts
MMP-2, (ng/ml)	202.9 \pm 32.2	294.7 \pm 70.5***	335.2 \pm 75.4***
MMP-9, (ng/ml)	461.3 \pm 325.5	358.7 \pm 276.6	339.4 \pm 182.6
TGF- β_1 (ng/ml)	107.0 \pm 91.1	122.6 \pm 70.8	86.7 \pm 47.3
MMP-2 _u (mcg/mmol)	0.03 \pm 0.01	0.85 \pm 1.71*	1.32 \pm 2.04***
MMP-9 _u (mcg/mmol)	0.02 \pm 0.03	0.15 \pm 0.43	0.35 \pm 1.18*
TGF- β_1 (mcg/mmol)	0.33 \pm 0.29	0.73 \pm 0.67	0.90 \pm 0.42**

Urinary excretion of matrix metalloproteinases and their inhibitors is related to albuminuria and renal fibrosis in type 1 diabetic patients

V.V. Klimontov, I.A. Bondar, A.P. Nadeev, E.M. Parfentyeva;
Novosibirsk State Medical University, Russian Federation.

Background and aims: Matrix metalloproteinases (MMPs) and metalloproteinase inhibitors play a principal role in extracellular matrix remodeling in renal glomeruli and interstitium and, therefore, is involved in pathogenesis of diabetic nephropathy (DN). The question remains whether urinary MMPs/MMP inhibitors could be the early markers of glomerular and interstitial fibrosis in diabetes. Thus, the aim of our study was to assess the relation between urinary excretion of MMPs and MMP inhibitors, albuminuria and the signs of renal fibrosis in type 1 diabetic patients.

Materials and methods: 64 patients with type 1 diabetes were examined, including 25 normoalbuminuric (group DN0), 30 microalbuminuric (group DN1) and 9 macroalbuminuric ones (group DN2). Urinary excretion of matrix metalloproteinase-2 (MMP-2), matrix metalloproteinases-9 (MMP-9), tissue inhibitor of matrix metalloproteinases-1 (TIMP-1), tissue inhibitor of matrix metalloproteinases-2 (TIMP-2), plasminogen activator inhibitor-1 (PAI-1) and type IV collagen was determined by ELISA and compared to control (10 healthy subjects, group C). Fractional mesangial and interstitial volume was estimated in kidney biopsy specimens in 7 DN0- and 14 DN1-patients.

Results: (median, percentile 25-75). Urinary excretion (pg/ μ mol creatinine) of investigated MMPs, MMP inhibitors and type IV collagen is shown in the table.

Group	MMP-2	MMP-9	TIMP-1	TIMP-2	PAI-1	Type IV collagen
C	4.1 (2.5-6.0)	0.33 (0.22-0.70)	245 (39-973)	28.1 (12.8-56.6)	3.2 (2.3-6.2)	2.9 (2.2-4.3)
DN0	4.6 (2.5-7.5)	0.6 (0.34-1.73)	608 (22-1543)	30.5 (11.1-42.7)	5.3 (3.1-6.8)	3.6 (3.1-5.3)
DN1	6.0 (3.5-10.5)	0.87 (0.43-8.52)*	801 (32-1475)	31.8 (11.4-47.5)	7.0 (3.6-12.7)*	5.1 (2.8-7.8)*
DN2	16.1 (9.3-17.0)*	1.07 (0.50-1.45)	3104 (2233-5782)*	45.6 (43.5-54.2)	10.3 (6.1-19.3)*	15.2 (9.6-17.0)*

* $p<0.05$ vs. group C.

All parameters correlated positively with albuminuria (MMP-2: $r=0.71$; MMP-9: $r=0.29$; TIMP-1: 0.56 , TIMP-2: $r=0.57$; PAI-1: 0.41 ; all $p<0.05$). Significant correlations were found between excretion of type IV collagen and MMP inhibitors: TIMP-1 ($r=0.42$), TIMP-2 ($r=0.33$), PAI-1 ($r=0.39$). The increased TIMP-1 excretion was related to mesangial expansion ($r=0.44$), meanwhile TIMP-2 and PAI-1 correlated positively with the volume of interstitium ($r=0.39$ and $r=0.54$ respectively).

Conclusion: In type 1 diabetic patients increased urinary excretion of MMPs and MMP inhibitors is associated with albuminuria and the signs of glomerular and interstitial fibrosis.

Urinary sulphate excretion is a predictor for progression of diabetic nephropathy

G. Andrésdóttir¹, S.J.L. Bakker², H.P. Hansen¹, H.-H. Parving^{3,4}, P. Rossing¹;
¹Steno Diabetes Center, Gentofte, Denmark, ²University Medical Center Groningen, Netherlands, ³Department of Endocrinology Rigshospitalet, Copenhagen, ⁴Faculty of Health Science Århus University, Denmark.

Background and aims: Recently Hydrogen sulphide (H₂S) has emerged as a potentially important mediator of cardiovascular homeostasis and cytoprotection. H₂S is in part produced in the vasculature from L-cysteine where it mediates smooth muscle relaxation and subsequent vasodilatation. H₂S is converted to sulfite in the mitochondria, and then further oxidized to thio-sulphate and sulphate. The sulphates are finally excreted in the urine. It has been proposed that the biosynthesis of H₂S is reduced due to diabetes-related endothelial dysfunction. There is also some evidence that H₂S is the primary vessel-relaxing agent for small blood vessels. We have therefore measured the urinary excretion of sulphate in patients with type 1 diabetes (T1D) and diabetic nephropathy (DN) in order to evaluate if the sulphate excretion can predict progression of nephropathy.

Materials and methods: The study was a post hoc study of a prospective, randomized, unmasked, controlled trial. Originally 82 T1D patients with progressive DN were followed for 4 years, comparing the effects of a low-protein diet (0.6g/kg/day) with a usual-protein diet on decline in GFR (plasma clearance of ⁵¹Cr-EDTA) and development of ESRD or death. Sulphate excretion was measured by ion exchange chromatography in 24h urine at baseline, 2 years and 4 years. Data on sulphate was available for 65 of the subjects.

Results: There were 43 men and at baseline age [mean (SD)] was 40.1 (7.8) years. Baseline GFR was 71 (31) ml/min/1.73m². Baseline sulphate excretion [geometric mean (2.5-97.5% estimated centiles (EC))] was 10.0 (2.8-35.2) mmol/day. During follow-up decline in GFR was 3.8 (3.0) ml/min/year. Baseline log u-sulphate was associated with logAER ($p=0.011$, $r=0.313$), protein intake ($p<0.001$, $r=0.632$) and age at baseline ($p=0.001$, $r=-0.392$). It was not associated with baseline values for; GFR, HbA_{1c}, BP, cholesterol, assigned diet group, sex, tobacco use, use of antihypertensive medication or presence of cardiovascular disease at baseline. Baseline log u-sulphate excretion showed a significant negative association with the rate of decline in GFR ($p=0.015$, $r=-0.3$). When adjusted for diet, log AER and systolic BP at baseline, the correlation between sulphate and Δ GFR was even stronger ($p<0.001$, adj $r^2=0.32$). The same model without sulphate was weaker ($p=0.011$, adj $r^2=0.12$). During the study period sulphate excretion [geometric mean, (2.5-97.5% EC)] was 12.0 (5.0-28.8) mmol/day. Mean log u-sulphate during the study period was associated to the rate of decline GFR ($p=0.001$, $r=-0.402$), mean protein intake ($p<0.001$, $r=0.709$) and s-cholesterol ($p=0.034$, $r=-0.264$), but not to follow up values of BP, HbA_{1c}, logAER and HDL. The association was strong ($p<0.001$, adj $r^2=0.42$) when adjusted for mean values during follow-up of BP, logAER, HbA_{1c} and serum cholesterol (parameters found as independent

variables in the original study). The same model without sulphate was inferior ($p < 0.001$, adj $r^2 = 0.30$). We found similar results when we adjusted for assigned diet group and dietary protein intake (both $p < 0.001$, adj $r^2 = 0.41$).

Conclusion: We found that high urinary sulphate excretion is associated with slower rate of decline in GFR in diabetic nephropathy during four years of follow up, independent of known progression promoters.

High urinary sodium excretion and association with albumin excretion in patients with type 2 diabetes mellitus

M. Ahdi¹, E.W. Meesters¹, A.P. van Zanten², V.E.A. Gerdes^{1,3};

¹Internal Medicine, Slotervaart Hospital, ²Clinical Biochemistry, Slotervaart Hospital, ³Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands.

Background and aims: Urinary sodium excretion, as a measure of sodium intake, has been associated to urinary albumin excretion in population based studies. Guidelines for clinical diabetes care recommend monitoring and treatment of albuminuria and advice dietary sodium restriction (100 mmol per day) for patients with diabetes, however recommendations for the monitoring of urinary sodium excretion are lacking. In this study we examined the sodium excretion per day in a cohort of patients with type 2 diabetes, and evaluated the relationship between sodium excretion and albumin excretion.

Materials and methods: Between May 2009 and December 2010 consecutive patients with type 2 diabetes attended to the outpatient clinic for their yearly comprehensive diabetes investigation were included. Clinical data including blood pressure, BMI, smoking status, HbA1c and 24 hour urinary sodium, potassium and albumin excretion, were evaluated and registered in a standardized way. Data are presented as medians with interquartile range (IQR). The cohort was divided into quintiles according to sodium excretion. Chi-square and Kruskal Wallis tests were performed.

Results: A total of 983 patients (52% men) with median age 63 (range 25-91) years were included. Median duration of diabetes was 11 (range 0-51) years, and HbA1c 54 (46-63) mM/M. Twelve patients did not collect 24 hour urine and were excluded. Urinary sodium excretion per day was ≤ 114 mmol $24h^{-1}$ in the 1st quintile and ≥ 251 mmol $24h^{-1}$ in the 5th quintile. Only in the 1st quintile the sodium excretion was in the range as expected with recommended sodium restriction. Median urinary albumin excretion was 11 (4-34) mg $24h^{-1}$ in the 1st versus 32 (11-84) mg $24h^{-1}$ in the 5th (p for trend < 0.001). We observed a positive significant association between sodium excretion and BMI, male gender, creatinin clearance and potassium excretion and a negative association with age (p for trend for these variables < 0.001). No difference was found for blood pressure, smoking, diabetes duration and complications, HbA1c, uric acid, and type or number of antihypertensives. The percentage of patients with a sodium excretion ≥ 150 mmol $24h^{-1}$ increased with the severity of albuminuria from 56% in patients with normal levels to 67% and 80% in patients with microalbuminuria and proteinuria respectively ($P < 0.001$).

Conclusion: Sodium excretion per day was high in many patients and was positively related to the level of albuminuria. Since a beneficial effect of salt restriction is likely in patients with an elevated urinary albumin excretion, we suggest to measure 24 hour urinary sodium excretion to monitor salt intake and guide treatment.

Increased urinary excretion of cystatin C predict renal impairment in type 2 diabetes

M.R. Kim¹, B.G. Choi¹, J.H. Kang¹, Y.K. Jeon¹, S.S. Kim¹, B.H. Kim¹, C.W. Lee², Y.K. Kim³, I.J. Kim¹;

¹Department of Internal Medicine, Pusan National University Hospital,

²Department of Internal Medicine, Busan St. Mary's Hospital, ³Kim Yong Ki Internal Medicine Clinic, Busan, Republic of Korea.

Background and aims: Although albuminuria is one of the most conventional markers for the progression of diabetic nephropathy, it is casting doubt on the legitimacy of this marker for early detection of diabetic nephropathy. The aim of this study was to evaluate clinical usefulness of urine cystatin C (Ucyst C) levels in predicting renal impairment ($eGFR < 60$ mL/min/1.73m²).

Materials and methods: We studied 305 patients with type 2 diabetes who measured Ucyst C at baseline in Pusan National University between 2008 and 2010. We excluded 18 patients with $eGFR < 30$ mL/min/1.73m² at baseline.

Results: Of the 287 patients, 54 (18.8%) showed renal impairment ($eGFR < 60$ mL/min/1.73m²) during follow-up period. The median follow up period was 20 months. Ucyst C was significantly associated with renal impairment during follow-up period in univariate analysis ($P < 0.001$). A Cox proportional hazard regression model was used to analyze various factors for renal impairment in multivariate analysis. The factors that can predict renal impairment during follow-up was high Ucyst C level (Ucyst C > 0.1 mg/L; HR=2.706, 95% CI 1.471-4.977; $P=0.001$), age (HR=1.047, 95% CI 1.013-1.082; $P=0.006$) and SBP (HR=1.025, 95% CI 1.002-1.048; $P=0.029$). When we analyzed data of 264 patients with normo- and microalbuminuria, high Ucyst C level was the only factor to predict renal impairment during follow-up (HR=2.692, 95% CI; 1.320-5.489; $P=0.006$).

Conclusion: Ucyst C could be a useful marker for predicting renal impairment independently of other factors including albuminuria in type 2 diabetic patients.

1089

Increased urinary excretion of myo-inositol and D-chiro-inositol in diabetes occurs independently of hyperglycaemia in the isolated perfused kidney

K.M. Loomes, B. Choong, A. Phillips, H.-H. Chang;

School of Biological Sciences, University of Auckland, New Zealand.

Background and aims: Abnormal urinary clearance of the inositol sugars, myo-inositol (MI) and D-chiro-inositol (DCI), occurs in both diabetes mellitus and in polycystic ovary syndrome (PCOS). D-chiro-inositol is a putative insulin mimetic that lowers hyperglycemia in diabetes and in PCOS its increased urinary excretion is inversely correlated with insulin sensitivity. Currently, the mechanisms underlying increased urinary inositol excretion are unknown although it has been presumed that hyperglycemia is a major contributing factor. This conclusion is based in part on the inhibitory effect of high glucose on inositol uptake in cultured proximal tubular-derived cells via competition with inositol transporters. However, in vitro cultures of single-type cells do not represent the physiological function of the kidney where urinary excretion is regulated by the interplay of renal re-absorption, filtration, and excretion. Also, hyperglycemia does not explain the same phenomenon in PCOS which is characterised by a hyperinsulinemic state. The aim of the present study was to therefore investigate the significance of high glucose ambience on inositol excretion in diabetes using an intact physiological kidney system.

Materials and methods: The isolated perfused kidney was established, validated, and used to measure inositol excretion in kidneys from rats that had been diabetic for 4-weeks from streptozotocin injection. Kidneys isolated from saline-injected rats were used as a non-diabetic control. Kidney viability was assessed using several criteria including glomerular filtration rate (GFR), glucose re-absorption, sodium ion re-absorption, urinary flow rate and perfusion pressure. The perfusion system comprised a single pass pump-driven force perfusion containing 50μM MI and 5μM DCI. Diabetic and non-diabetic kidneys were perfused with perfusate containing either 5mM or 20mM glucose and stabilised for 40 minutes prior to collection of urine samples. MI and DCI concentrations were determined using GC/MS utilising deuterated myo-inositol as an internal standard.

Results: The isolated perfused kidney system successfully preserved the functionality of the kidney. Compared to the non-diabetic controls, diabetic kidneys perfused with either 5mM or 20mM glucose displayed impaired functionality with lower GFR and Na⁺ re-absorption. In diabetic kidneys perfused with 5mM glucose, the GFR-normalised urinary excretion of MI and DCI were increased by 1.4-fold and 4-fold ($p < 0.001$), respectively, compared to control kidneys. In both non-diabetic and diabetic kidneys perfused with 20mM glucose, there was a further potentiated increase in DCI excretion by approximately 1.4-fold ($p < 0.05$).

Conclusion: The primary cause of excessive urinary excretion of MI and DCI is due to a fundamental impairment in kidney function as a result of prolonged exposure to diabetes. It is also primarily a renal phenomenon as opposed to any systemic abnormality in inositol metabolism. The effects of hyperglycemia are secondary to this impairment in kidney function and were selectively pronounced for DCI. The selective 4-fold increase in DCI urinary excretion in the diabetic kidney is consistent with clinical observations in diabetes. As the increased DCI excretion also occurred under normoglycemic conditions, it is possible that a similar impairment in kidney function contributes to the abnormal urinary excretion of DCI in PCOS.

Trends in cost of prescription medication by stages of diabetic nephropathy in patients with type 1 diabetes between 1995 and 2005

R. Lithovius^{1,2}, V. Harjutsalo^{1,2}, M. Saraheimo^{1,2}, C. Forsblom^{1,2}, P.-H. Groop^{1,2}

¹FinnDiane Study Group, Institute of Genetics, ²Department of Medicine, Helsinki University Central Hospital, Finland.

Background and aims: While previous studies have established the relationship between medication cost and kidney failure, typically the cost with respect to earlier stages of the disease development are not considered. Using longitudinal data from a large nationwide prospective cohort of adult patients with type 1 diabetes, we were able to estimate the outpatient prescription medication use and costs by different stages of diabetic nephropathy.

Materials and methods: The Finnish Diabetic Nephropathy Study (FinnDiane) data (N=1 670) were linked to the Drug Prescription Register. Based on their urinary albumin excretion rate patients were divided into three nephropathy groups: normoalbuminuria, microalbuminuria and macroalbuminuria. The fourth group consisted of patients with a kidney transplant. Moreover, data on progression of renal disease were verified from baseline and follow-up visits as well as medical files, until 31 December 2005 and all non-progressors were included in this analysis. Costs were inflated to 2009 euro levels by using the Consumer Price Index. The mixed linear models were used to evaluate the annual costs during 1995–2005. In order to obtain information on co-morbidities we also linked the FinnDiane data with the Hospital Discharge Register and the Central Drug Register. Costs were adjusted for age, sex, contributing years, BMI, total insulin dose/day, co-morbidities and years with kidney transplant in the final multivariate models.

Results: After adjustment, differences were observed between different stages of nephropathy ($p=0.02$). Interaction between year and nephropathy stage was significant ($p<.0001$), which manifested as different cost profiles between groups. However, no differences were observed with respect to annual costs ($p=0.4$) and cost profiles ($p=0.9$) between normo- and microalbuminuria groups. Therefore, these two groups were pooled in the further analysis. Adjusted costs between 1995 and 2005 increased linearly in normo- and microalbuminuria by 37% (from €1226 to €1681) and in macroalbuminuria groups by 64% (from €1286 to €2109). Although the annual adjusted costs per patient were the highest in patients with kidney transplant, the costs decreased by 45% (from €8635 to €5973) during this period. In 1995 the adjusted cost difference between pooled (normo- and microalbuminuria) and macroalbuminuria groups was only 5% (€60), whereas in 2005 it increased to 26% (€428). The difference between macroalbuminuria and kidney transplantation was 5.7-fold (€7349) in 1995. However, the gap decreased by time and the costs were 1.8 times lower (3864€) in 2005.

Conclusion: Progression from normo- and microalbuminuria to more severe stages of nephropathy had a strong impact on prescription medication costs in patients with type 1 diabetes. The increasing trend in the costs among normo-, micro- and macroalbuminuric patients suggests that new and more expensive drugs and strict evidence-based guidelines have had an effect on the costs. In contrast, the decrease in the costs for those with kidney transplants indicates that the costs for immunosuppressants have decreased probably due to expired patents, price competition and generic substitution.

1091

Risk of major renal events in people with type 2 diabetes: prediction models based on the ADVANCE study population

M.E. Cooper¹, S. Zoungas^{2,3}, M. Jardine², J. Hata², V. Perkovic², T. Ninomiya², H. Arima², M. Woodward², A. Cass², P. Hamet⁴, M. Marre⁵, C.E. Mogensen⁶, A. Patel¹, J. Chalmers²

¹The Baker IDI Heart and Diabetes Institute, Melbourne, ²The George Institute for Global Health, Sydney, ³School of Public Health and Preventive Medicine, Monash University, Melbourne, Australia, ⁴University of Montreal, Canada, ⁵Université Paris 7, France, ⁶Medical Department M, Aarhus Sygehus, Denmark.

Background and aims: Among patients with type 2 diabetes, the incidence of kidney disease continues to contribute to significant morbidity and mortality. However to date, insufficient data have been available to develop reliable risk prediction tools. We developed a risk prediction model for major renal

events in patients with diabetes using the data from the Action in Diabetes and Vascular Disease: Preterax and Diamicon Modified Release Controlled Evaluation (ADVANCE) trial.

Materials and methods: ADVANCE recruited 11,140 participants with type 2 diabetes aged ≥ 55 years, with a history of major macrovascular or microvascular disease or at least one other risk factor for vascular disease. Major renal events were defined as the composite of renal replacement therapy, renal death or doubling of serum creatinine to $\geq 200\mu\text{mol/l}$. The risk prediction model was developed using baseline characteristics in Cox proportional hazards regression with adjustment for randomised treatments (blood pressure lowering and glucose control interventions).

Results: During a median of 5 years follow up, 166 major renal events were recorded. Significant predictors for subsequent major renal event in the multivariable analysis were estimated GFR, urine albumin/creatinine ratio, systolic blood pressure, HbA1c, presence of diabetic retinopathy, male sex and level of formal education. When applied to the ADVANCE cohort, this model demonstrated good discrimination (area under the receiver operating characteristic curve, 0.83; 95% CI, 0.80–0.87) and excellent calibration (Hosmer-Lemeshow χ^2 statistic 8.37, df=9, $p=0.50$).

Conclusion: This simple model comprising 7 variables routinely assessed in clinical practice can accurately predict the risk of major renal outcomes in patients with type 2 diabetes. This model requires validation in an external cohort.

Clinical Trial Registration Number: NCT00145925

Telmisartan attenuates diabetic nephropathy through anti-oxidative and anti-inflammatory actions via activation of peroxisome proliferator-activated receptor- γ

N. Kajitani, K. Shikata, R. Kodera, S. Miyamoto, D. Hirota, C. Sato, J. Wada, D. Ogawa, H. Makino;

Medicine and Clinical Science, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Science, Japan.

Background and aims: Microinflammation contributes to the pathogenesis of diabetic nephropathy. We previously reported that pioglitazone, peroxisome proliferator-activated receptor (PPAR)- γ agonist, inhibits macrophage infiltration into kidney and exerts renoprotective effects via anti-inflammatory effects in diabetic rats. Telmisartan, which is an angiotensin receptor blocker, is reported to act as PPAR- γ partial agonist. The aim of this study is to investigate the renoprotective effects of telmisartan via activation of PPAR- γ .

Materials and methods: Five-week male SD rats were used in this study. Diabetes was induced by intravenous injection of streptozotocin at 65mg/kg body weight. Non diabetic control rats were administered with citrate buffer instead of streptozotocin. Diabetic rats were divided into three groups, and administered with each drug for 8 weeks after induction of diabetes: The first group (TEL) is administered with telmisartan 5mg/kg body weight daily by gavage, the second group (GW) is administered with telmisartan 5mg/kg and GW9662, selective PPAR- γ antagonist, 0.5mg/kg daily by gavage, and the last group (HYD) is administered with hydralazine 5mg/kg daily in drinking water (diabetic controls). AER, blood pressure, blood glucose level were measured at 2, 4, 8 weeks. We collected kidney, blood and urine samples at 8 weeks, and metabolic data, histology and morphometry were evaluated.

Results: No significant difference for the level of HbA1c was observed between the diabetic three groups. No significant difference for the level of blood pressure was observed between the diabetic three groups and non diabetic control group. AER at 8 weeks was significantly reduced in TEL compared with HYD (HYD $947\pm 148\mu\text{g/day}$ (Mean \pm SE) vs. TEL $438\pm 46.3\mu\text{g/day}$, $p=0.01$), and the effect of telmisartan was partially antagonized by administration of GW9662 (GW $736\pm 97.1\mu\text{g/day}$). Mesangial matrix expansion was observed in diabetic rats, however, the expansion was significantly suppressed in TEL compared with HYD ($p<0.05$), and the effect of telmisartan was partially antagonized by GW9662. Glomerular expression of ICAM-1 and type IV collagen was increased in diabetic rats, however, the expression was significantly suppressed in TEL compared with HYD (ICAM-1; $p<0.001$, type IV collagen; $p<0.05$), and the effect of telmisartan was partially antagonized by GW9662. Urinary excretion of 8-Hydroxydeoxyguanosine was increased in diabetic rats, however, the expression was significantly suppressed in TEL compared with HYD, and the effect of telmisartan was partially antagonized by GW9662. Gene expression of CD14 in renal cortex was significantly up-regulated in diabetic rats, however, the expansion was suppressed in TEL compared with HYD, and the effect of telmisartan was partially antagonized

by GW9662. The number of infiltrated macrophages into the glomeruli was increased in diabetic rats, however, the number was significantly decreased in TEL compared with HYD ($p<0.001$), and the effect of telmisartan was partially antagonized by GW9662. The same result was observed about sialoadhesin positive activated macrophages.

Conclusion: These results suggest that telmisartan exerts renoprotective effects through anti-oxidative and anti-inflammatory actions via activation of PPAR- γ in diabetic rats.

Effectiveness of angiotensin II receptor antagonists in a Dutch cohort of patients with type 2 diabetes (ZODIAC-14)

H.J.G. Bilo^{1,2}, K.J.J. van Hateren¹, I. Drion¹, H. Joosten², S.J.L. Bakker², G.W.D. Landman¹, K.H. Groenier³, S.J.J. Logtenberg^{1,4}, N. Kleefstra^{1,2};

¹Diabetes Centre, Isala Clinics, Zwolle, ²Department of Internal Medicine, University Medical Center Groningen, ³Department of General Practice, University Medical Center Groningen, ⁴Department of Internal Medicine, Isala Clinics, Zwolle, Netherlands.

Background and aims: Blockage of the renin-angiotensin system (RAS) is an important therapeutic option to treat hypertension and/or albuminuria in patients with type 2 diabetes mellitus (T2DM). In this current study, we investigated the effects of different ARBs on blood pressure and albuminuria after 1 year in a large cohort of patients with T2DM.

Materials and methods: In 2007, 24940 primary care patients with T2DM participated in the ZODIAC study, a prospective observational study. Of these patients, 4810 (19%) patients were on ARBs. One year follow-up data were available for 3912 patients, of whom 3678 (94%) still used an ARB. A general linear model (GLM) for univariate analyses was used to estimate effects of losartan, irbesartan and a combined group of other ARBs on systolic blood pressure (SBP) and albuminuria. Analyses were repeated in strata according to baseline hypertension (SBP <140 mmHg and SBP \geq 140 mmHg) and albuminuria (albumin creatinine ratio (ACR) \geq 2.5 mg/mmol in men and \geq 3.5 mg/mmol in women). Because of skewed distribution ACR was logarithmically transformed (LnACR). Age, gender, baseline SBP, baseline LnACR, presence of macrovascular complications, use of diuretics and insulin were entered as covariates. Bonferroni was used to adjust for multiple comparisons. **Results:** A total of 1863 patients were on losartan, 1292 on irbesartan and 1655 on another ARB. Data on blood pressure in 2007 and 2008 were missing in 3% and 1% of all patients respectively. For ACR the proportions were 31% and 15% respectively. Use of diuretics and insulin was (significantly) higher in patients on irbesartan. Presence of macrovascular complications was lowest in the losartan group and highest in the combined group. No relevant or significant differences were found between groups concerning age, sex, blood pressure, albuminuria, renal function and use of other antihypertensive or glucose lowering drugs. Mean LnACR values in 2007 were 0.57, 0.62 and 0.35 in the losartan, irbesartan and the combined group of other ARBs, respectively. Median ACR in 2007 and 2008 were 1.0 in all groups. Results are presented in table 1. We found a significantly higher ACR in patients with SBP <140 mmHg on Irbesartan vs. other ARBs.

Conclusion: In this observational study with one year follow-up, different ARBs were equivalent with respect to the effects on blood pressure and ACR, except for a significant difference between Irbesartan vs. other ARBs in ACR in patients with normal baseline SBP, although this difference is hardly relevant.

Table 1.

	All (n=4810)	SBP <140 mmHg (n=1650)	SBP \geq 140 mmHg (n=2994)	No albuminuria (n=2455)	Albuminuria (n=873)

Initial angiotensin receptor blockade-induced decrease in albuminuria predicts long term renal outcome in type 2 diabetic patients with microalbuminuria

M.E. Hellemons¹, F. Persson², S.J.L. Bakker¹, P. Rossing², H.-H. Parving³, D. de Zeeuw¹, H.J. Lambers Heerspink¹;

¹Clinical Pharmacology & Nephrology, University Medical Center Groningen, Netherlands, ²Department of Medical Endocrinology, Steno Diabetes Center, Gentofte, ³Department of Medical Endocrinology, University Hospital of Copenhagen, Denmark.

Background and aims: We aimed to investigate the individual impact of initial responses in urinary albumin excretion (UAE) and systolic blood pressure (SBP) to Angiotensin-Receptor-Blockade (ARB) treatment on long term renal outcome in patients with type 2 diabetes and microalbuminuria.

Materials and methods: In a post-hoc analysis of the IRMA-2 trial we first assessed the individual variability in UAE and SBP-response (0-6 months) in 531 subjects. Subsequently, we analyzed the individual effect of both response parameters on renal outcome defined as change in estimated glomerular filtration rate (eGFR) during 2 years of follow-up.

Results: The median reductions in UAE and SBP in the population were -18% and -11mmHg respectively. In Irbesartan treated patients, 85 patients (24%) had a robust (>median) reduction in UAE but not in SBP (discordant SBP-response) and 67 patients (19%) had a robust (>median) reduction in SBP but not in UAE (discordant UAE-response). The degree of reduction in UAE was independently associated with the rate of eGFR decline ($p=0.0037$). SBP showed a similar trend ($P=0.087$). The relation between a larger UAE-reduction and a slower rate of renal function decline was present in both the cohort with a SBP-change above and below the median.

Conclusion: Within an individual UAE response to ARB-therapy may be discordant from SBP-response. The initial change in UAE was independently associated with eGFR slope: the more UAE reduction the less eGFR decline, irrespective of the SBP-change. These results suggest that in microalbuminuric patients with type 2 diabetes, UAE should be monitored after initiation of therapy and a separate target for renoprotective therapy.

Effects of valsartan add-on treatment on aldosterone breakthrough in type 2 diabetic patients with hypertension receiving enalapril

G. Yasuda, K. Yatsu, N. Hirawa, Y. Yamamoto;

Nephrology, Yokohama City University, Japan.

Background and aims: Angiotensin II receptor antagonists (ARB) are the first choice for treatment of hypertension and prevention of organ damage in diabetic patients with hypertension. One of the major effects of ARB is to decrease plasma aldosterone concentration (PAC) for cardiovascular protection. However, long-term ARB therapy is associated with increased PAC, which is known as 'aldosterone breakthrough'. Coadministration of ARB and angiotensin converting enzyme inhibitors (ACEI) is more effective for the treatment of hypertension than monotherapy of either in diabetic patients with hypertension. Nevertheless, little is known about the effect of coadministration of both agents on aldosterone breakthrough.

Materials and methods: This prospective randomized parallel-group study was designed to compare the effects of adding valsartan (ARB) to enalapril (ACEI) and doubling the dose of enalapril in type 2 diabetic patients whose

blood pressure did not reach the therapeutic goal (140/90 mmHg) by enalapril (5 mg/day) monotherapy. Fifty-four patients (63 ± 7 years old, 32 men and 22 women, serum creatinine levels < 1.5 mg/dL) already on enalapril 5 mg/day were assigned to receive either a double dose of enalapril (10 mg) or valsartan (80 mg) added to enalapril (5 mg) for 48 weeks. Plasma renin activity (PRA) and PAC were measured at 0, 12, 24 and 48 weeks.

Results: Both groups showed significant ($p < 0.05$) decreases in blood pressure during the treatment period from 148/94 at 0 week to 132/86 mmHg at 12 weeks in the enalapril double-dose group and from 150/95 at 0 week to 134/84 mmHg at 12 weeks in the valsartan add-on group). In the valsartan add-on group, PAC decreased from 86 ± 6 at 0 week to 65 ± 5 pg/mL at 12 weeks ($P < 0.05$) and maintained similar levels during therapy. However, in the enalapril double-dose group, PAC initially decreased from 84 ± 7 (0 week) to 65 ± 6 pg/mL ($P < 0.05$) at 12 weeks but returned to the baseline level (81 ± 7 pg/mL) at 24 weeks. PRA increased from 1.7 ± 0.5 (0 week) to 4.4 ± 1.0 ng/mL/h ($p < 0.01$, 12 week) in the valsartan add-on group and from 1.9 ± 0.4 (0 week) to 4.7 ± 1.2 ng/mL/h ($p < 0.01$, 24 week) in the enalapril double-dose group.

Conclusion: These findings suggest that adding valsartan to enalapril suppresses aldosterone breakthrough more effectively than increasing the dose of enalapril. Aldosterone increases cardiac fibrosis and promotes ventricular remodeling, which incurs high mortality in type 2 diabetic patients with hypertension. Thus, coadministration of ACEI and ARB may minimize these aldosterone-induced deleterious effects.

1096

Effects of valsartan on osteoprotegerin and receptor activator of nuclear factor kappa B ligand levels in patients with type 2 diabetes, systolic hypertension and microalbuminuria

J. Karalliedde¹, B. Shah¹, Y. Wang², G. Maltese¹, G. Viberti¹, L. Gnudi¹

¹Cardiovascular Division, King's College London, ²Division of Primary Care and Public Health Sciences, King's College London, UK.

Background and aims: Osteoprotegerin (OPG) and Receptor Activator of Nuclear factor- κ B Ligand (RANKL) are important glycoproteins involved in bone homeostasis. The OPG/RANKL axis may play a role in cardiovascular disease (CVD). Recent studies have reported a positive correlation between OPG and aortic pulse wave velocity (Ao-PWV), an index of arterial stiffness and an independent marker of CVD. We have previously demonstrated that in patients with Type 2 Diabetes Mellitus (T2DM), systolic hypertension and microalbuminuria, treatment with Valsartan and Hydrochlorothiazide (VAL/HCTZ), as compared to Amlodipine (AML) significantly reduced Ao-PWV and albumin excretion rate (AER) independent of blood pressure control. Our objective was to evaluate whether the beneficial effect of VAL/HCTZ on Ao-PWV correlated with changes in OPG and RANKL serum levels.

Materials and methods: In a 24 week double-blind, parallel group study we evaluated the effects of VAL/HCTZ vs. AML on the primary outcome Ao-PWV, in 131 T2DM patients with systolic hypertension, raised AER and preserved renal function. HCTZ was added to VAL to ensure equivalent blood pressure control vs. AML. In this post-hoc study we measured serum OPG and RANKL levels in 125 (VAL/HCTZ $n=64$, AML $n=61$) subjects. Serum OPG and RANKL levels were determined by enzyme-linked immunosorbent assay from samples obtained at baseline and end of the study. Ao-PWV was measured by applanation tonometry. All measurements and statistical analyses were performed blinded to group allocation.

Results: There were no significant baseline differences between the two groups in age, gender, duration of diabetes, renal function, blood pressure measures and glycaemic control. Following 24 weeks, Ao-PWV was reduced to a significantly greater extent with VAL/HCTZ, mean (95%CI), -1.7 (-1.1 , -2.3) m/s as compared to AML, -0.5 (0.04 , -1.03) m/s, $p < 0.001$. At baseline, a linear regression model showed that neither OPG nor RANKL levels demonstrated a significant relationship with Ao-PWV. The differential effects of treatment on Ao-PWV did not correlate with changes in serum OPG and RANKL levels or their ratio. No significant effect of treatment (VAL/HCTZ vs. AML) was observed on OPG and RANKL serum levels, and their ratio. Based on multivariate regression analysis, OPG and RANKL changes (Final - Baseline) only associated with gender ($p=0.014$ for OPG, $p=0.06$ for RANKL), while OPG/RANKL ratio change (Final - Baseline) associated with log C-reactive protein ($p=0.007$). However, OPG, RANKL and OPG/RANKL ratio did not associate with treatment type and any other baseline characteristics.

Conclusion: The observed significant reduction in Ao-PWV by Valsartan is not associated with changes OPG or RANKL levels. These results suggest that

OPG and RANKL serum levels are unlikely to mediate the blood pressure independent cardiovascular protective properties of angiotensin receptor blockers in T2DM.

Glycosylation gap is influenced by Irbesartan treatment in patients with type 2 diabetes and microalbuminuria

P.J. Thornalley¹, A. Adaikalakoteswari¹, K. Rossing², P. Rossing², H.-H. Parving³, N. Rabbani¹

¹Warwick Medical School, University of Warwick, UK, ²Steno Diabetes Center, Copenhagen, ³Department of Medical Endocrinology, University of Copenhagen Hospital, Denmark.

Background and aims: Inhibition of the renin-angiotensin-aldosterone system by the use of angiotensin II receptor blockers (ARBs) and angiotensin converting enzyme inhibitors is considered a first-line treatment modality for diabetic patients with microalbuminuria. Irbesartan is a potent and selective angiotensin II subtype 1 receptor ARB used in the treatment of diabetic nephropathy. The aim of this study was to assess the effect of Irbesartan on the glycosylation gap - the difference between measured HbA_{1c} and that computed from measured plasma fructosamine content.

Materials and methods: Fifty-two hypertensive type 2 diabetic patients with microalbuminuria (41 males) were recruited from our center. At inclusion, antihypertensive treatment was discontinued and replaced with bendroflumethiazide, 5 mg once daily, and following 2-months washout (baseline), patients were treated with Irbesartan, either 300 mg (17 patients), 600 mg (17 patients), or 900 mg (18 patients) once daily, for 2 months. HbA_{1c} and plasma protein fructosamine content were recorded and the glycosylation gap deduced at baseline and post-Irbesartan treatment. Plasma protein fructosamine content was determined by stable isotopic dilution analysis liquid chromatography-tandem mass spectrometry of exhaustive enzymatic digests.

Results: Irbesartan treatment produced a negative shift in the glycosylation gap: baseline $0.00 \pm 1.15\%$ versus $-3.24 \pm 1.15\%$ ($P < 0.001$; paired t-test). There was no difference in glycosylation gap between treatment groups at baseline but there was after Irbesartan treatment ($P < 0.01$, one-way ANOVA), attributed to a greater change in glycosylation gap by 600 mg o.d. Irbesartan treatment than for 300 and 900 mg o.d. doses. Glycosylation gap by Irbesartan dose was: 300 mg o.d., $-3.18 \pm 1.18\%$; 600 mg o.d., $-3.98 \pm 1.04\%$ ($P < 0.05$, with respect to 300 mg o.d.); and 900 mg o.d., $-2.61 \pm 1.19\%$ ($P < 0.001$, with respect to 600 mg o.d., t-test). The marked negative shift of the glycosylation gap with Irbesartan treatment was due to increase in plasma fructosamine, probably linked to decreased clearance of glycated albumin when the glomerular filter is tightened with Irbesartan treatment.

Conclusion: Irbesartan treatment produced a negative shift of glycosylation gap in patients with type 2 diabetes and microalbuminuria. This is the first demonstration of renin-angiotensin-aldosterone system directed treatment influencing the glycosylation gap.

Impact of glycaemic control on the effect of direct renin inhibition in the AVOID study

F. Persson¹, J.B. Lewis², E.J. Lewis³, P. Rossing¹, N.K. Hollenberg⁴, H.-H. Parving^{5,6}

¹Steno Diabetes Center, Gentofte, Denmark, ²School of Medicine, Vanderbilt University, Nashville, USA, ³Medical Center, Rush University, Chicago, USA, ⁴Brigham and Women's Hospital, Harvard University, Boston, USA, ⁵Medical Endocrinology, Rigshospitalet, Copenhagen, Denmark, ⁶Faculty of Health Science, Aarhus University, Denmark.

Background and aims: Hyperglycaemia induces development and progression of microvascular complications in diabetes. Furthermore, a new direct link between high glucose levels and intrarenal renin-angiotensin activation has been demonstrated. This post hoc analysis assessed the influence of baseline glycaemic control (HbA_{1c}) on the reduction of albuminuria of aliskiren or placebo added to losartan in the Aliskiren in the Evaluation of Proteinuria In Diabetes (AVOID) study.

Materials and methods: In AVOID, 599 patients aged 18–85 years with type 2 diabetes, hypertension and nephropathy received 6 months' aliskiren (150 mg force titrated to 300 mg after 3 months) or placebo added to losartan 100 mg and optimal antihypertensive therapy. Key exclusion criteria were non-diabetic kidney disease, estimated glomerular filtration rate (eGFR) <30 mL/min/1.73 m² and serum potassium >5.1 mmol/L. Changes in urinary albumin creatinine ratio (UACR) at end of study were assessed by tertiles of baseline HbA_{1c} levels.

Results: Patient baseline characteristics showed no notable differences between HbA_{1c} subgroups. Patients were divided into tertiles of HbA_{1c} (<7.1%, ≥7.1–<8.4% and ≥8.4% respectively). Whereas mean HbA_{1c} did not change during the study in patients receiving aliskiren (baseline 8.0%, endpoint 8.0%), there was a 0.2% increase in mean HbA_{1c} in the placebo group (baseline 7.9%, endpoint 8.1%; $p = 0.012$ vs aliskiren). In the overall population, adding aliskiren to losartan reduced UACR by 20% compared to placebo ($p < 0.001$). The antiproteinuric effect of aliskiren was consistent across subgroups of baseline glycemic control, with the largest effect (tertile 1 vs. 3, $p=0.052$) in the tertile with baseline HbA_{1c} ≥8.4% (Table). In linear regression analysis there was no association between baseline HbA_{1c} and reduction in UACR in the aliskiren treated group.

Conclusion: This post hoc analysis of the AVOID study suggests that renin inhibition with aliskiren 300 mg once daily added to losartan 100 mg once daily plus optimal antihypertensive therapy provides reductions in UACR that are efficacious in all, but particularly in poorly controlled diabetic patients.

HbA _{1c} tertile	Aliskiren UACR ratio (95% CI) for (end of study:baseline)	Placebo UACR ratio (95% CI) for (end of study:baseline))	Geometric mean ratio (95% CI) for UACR (aliskiren:placebo)	p-value
HbA _{1c} <7.1%	0.92 (0.78–1.10)	1.07 (0.92–1.24)	0.86 (0.69–1.08)	0.196
HbA _{1c} ≥7.1% and <8.4%	0.81 (0.69–0.95)	0.96 (0.84–1.09)	0.85 (0.69–1.03)	0.104
HbA _{1c} ≥8.4%	0.73 (0.61–0.87)	0.99 (0.81–1.22)	0.73 (0.56–0.95)	0.021

Spirolactone diminishes urinary albumin excretion in type 1 diabetic patients with microalbuminuria: a randomised placebo-controlled crossover study

S. Nielsen¹, F. Persson¹, E. Frandsen², T. Sugaya³, G. Hess⁴, D. Zdunek⁵, K. Schjoedt¹, H.-H. Parving^{6,7}, P. Rossing¹

¹Dep. 520, Steno Diabetes Center, 2820 Gentofte, ²Dep. 520, Glostrup Hospital, Denmark, ³Riken Kobe Institute, Hyogo, Japan, ⁴University of Mainz, Germany, ⁵Roche Diagnostics, Rotkreuz, Switzerland, ⁶University Hospital Copenhagen, ⁷Aarhus University, Denmark.

Background: It has been shown that adding the aldosterone receptor blocker spironolactone to standard renoprotective treatment, including renin-angiotensin-aldosterone system (RAAS) blockade in diabetic nephropathy, provides additional antiproteinuric effects. We examined the antiproteinuric effect of spironolactone on markers of glomerular and tubular damage in type 1 diabetic patients with persistent microalbuminuria.

Material and methods: We performed a randomized, placebo controlled, double blind, crossover study in 21 type 1 diabetic patients with microalbuminuria using spironolactone 25 mg or placebo once daily for 60 days, added to optimal antihypertensive treatment including RAAS blockade in maximal recommended doses. After both treatment periods, endpoints were evaluated: urinary(u)-albumin excretion/24hour(h), 24h blood pressure, glomerular filtration rate (GFR) and markers of tubular damage: urinary liver-type fatty-acid binding protein (LFABP), neutrophil gelatinase associated lipocalin (NGAL) and kidney injury molecule 1 (KIM1).

Results: All patients completed the study. During spironolactone treatment, u-albumin excretion was reduced by 60% (21–80) from 90 mg/24h to 35mg/24h when compared with placebo ($p=0.01$). Blood pressure (24h) did not change during spironolactone treatment ($p>0.2$ for all comparisons), and GFR decreased from 78(8) to 72(6) mL/min/1.73m² ($p=0.003$). The tubular markers u-LFABP, u-NGAL and u-KIM1 did not change during treatment ($p>0.3$ for all comparisons). Treatment was well-tolerated, two patients developed severe hyperkalemia (plasma potassium=5.7 mmol/L), which were sufficiently treated with diuretics and dietary intervention.

Conclusions: We demonstrated that spironolactone treatment on top of recommended optimal renoprotective treatment in microalbuminuric type 1 diabetic patients, may offer additional renoprotection independent of effects on systemic blood pressure. Plasma potassium should be monitored carefully. Clinical Trial Registration Number: Eudra CT: 2008-004839-38

Blood pressure control in hypertensive patients with diabetes mellitus and impaired renal function in real life: results of the 3A registry

U. Zeymer¹, R. Dechend², E. Deeg¹, E. Kaiser³, J. Senges¹, R. Schmieder⁴,
¹Institut für Herzinfarktforschung, Ludwigshafen, ²Helios-Klinikum Buch, Berlin, ³Novartis, Nürnberg, ⁴Nephrologie und Hypertensiologie, Erlangen, Germany.

Background: Blockade of the renin angiotensin aldosterone system is recommended in patients with arterial hypertension and diabetes mellitus. There are only few prospective data on blood pressure control in patients with diabetes mellitus and impaired renal function with the direct renin inhibitor aliskiren in a daily practice setting available.

Methods: In the non-interventional 3A Registry patients were eligible for inclusion in whom the physician had decided to initiate or modify the anti-hypertensive therapy. This included treatment with the direct renin inhibitor aliskiren or an ACE inhibitor (ACE-I)/angiotensin receptor blocker (ARB) or agents not blocking the renin-angiotensin-system (RAS), alone or on top of an existing drug regimen. Patients were prospectively followed for 1 year. Here we report the results of the prespecified subgroup of patients with diabetes mellitus without (GFR \geq 60 ml/min and with impaired renal function (GFR < 60 ml/min).

Results: Of the 14841 patients recruited by 923 physicians in Germany in 2008 and 2009, 4242 (28%) patients were diabetics. Of these 1334 patients had a GFR < 60 ml/min. The following results with respect to office and 24-hr ambulatory blood pressure after 1 year in the 3 groups were obtained:

	Aliskiren containing regimen	ACE-I/ARB containing regimen	No RAS blockade containing regimen
GFR \geq 60 ml/min			
mean reduction in syst/diast BP (%)	10.2 \pm 12/7.8 \pm 13	8.9 \pm 13/6.6 \pm 14	8.4 \pm 12/6.4 \pm 14
Mean reduction in 24-hr amb. BP (%)	6.8 \pm 10/6.2 \pm 12	5.7 \pm 9/4.0 \pm 12	5.4 \pm 9/6.0 \pm 10
GFR < 60 ml/min			
mean reduction in BP (%)	10.9 \pm 12/7.2 \pm 12	7.4 \pm 12/5.2 \pm 10	8.3 \pm 12/5.5 \pm 12
Mean reduction in 24-amb. BP (%)	6.3 \pm 11/5.2 \pm 12	5.4 \pm 9/4.0 \pm 11	5.9 \pm 9/4.2 \pm 10

Conclusions: In this large real life registry in hypertensive patients with diabetes an aliskiren-containing regimen showed better blood pressure reductions than patients without RAS-blockade, or an ACE-I/ARB-containing regimen, especially in patients with impaired renal function. Therefore treatment with aliskiren might be especially considered in diabetics.

Is the inverse relationship between blood pressure and mortality in elderly patients with type 2 diabetes caused by heart failure? (ZODIAC-25)

K.J.J. van Hateren¹, G.W.D. Landman¹, N. Kleefstra¹, K.H. Groenier², S.T. Houweling³, J. Struck⁴, G. Navis⁵, S.J.L. Bakker⁵, H.J.G. Bilo¹;

¹Diabetes Centre, Zwolle, ²Department of General Practice, University Medical Center Groningen, ³Langerhans Medical Research Group, Zwolle, Netherlands, ⁴Research Department, Thermo Fischer Scientific, BRAHMS Biomarkers, Hennigsdorf, Germany, ⁵Department of Internal Medicine, University Medical Center Groningen, Netherlands.

Background and aims: Several studies have found an inverse association of blood pressure with mortality in elderly patients with type 2 diabetes mellitus (T2DM). Unfortunately, a measure of heart failure, which may be the explanation for the inverse relationship observed, was lacking in those studies. Our aim was to investigate whether adjustment for a measure of heart failure influences the inverse relationship of blood pressure with mortality.

Materials and methods: In 1998, 326 elderly primary care patients with T2DM (>75 years) participated in the ZODIAC study. We found in a recent

study that prognostic properties of MR-proANP are comparable to those of N-terminal pro-B-type natriuretic peptide. Because of skewed distribution, MR-proANP was logarithmically transformed (LnMR-proANP). After a follow-up time of 10 years, updated means for systolic blood pressure, diastolic blood pressure and pulse pressure were calculated. To evaluate the association of the different measures of blood pressure with cardiovascular (CV) and all-cause mortality over time, data were entered as time dependent covariates in a Cox proportional hazard model. We used three different models. In model 1 we adjusted for age, sex, smoking, body mass index, duration of diabetes, serum creatinine, cholesterol-HDL ratio, macrovascular complications, albuminuria and use of lipid lowering and antihypertensive drugs. In models 2 and 3, we additionally adjusted for LnMR-proANP as a continuous variable and MR-proANP categorised into tertiles, respectively.

Results: Median MR-proANP was 125 pmol/L (interquartile range 83-187 pmol/L). During follow-up, 267 (82%) patients died, of which 114 patients (43%) from CV causes. The results of the Cox regression analyses are presented in table 1 (all hazard ratios refer to a pressure increase of 10 mmHg). For CV mortality, inverse relationships were found for systolic blood pressure and pulse pressure. All blood pressure indices were inversely associated with all-cause mortality. Although MR-proANP was independently associated with both CV and all-cause mortality, the inverse relationships between blood pressure indices and mortality did not change after adjustment for MR-proANP.

Conclusion: Although heart failure is highly prevalent in elderly patients with T2DM, the inverse relationship between blood pressure and mortality did not change after adjustment for a measure of heart failure. Based on these results it has become less plausible that heart failure is the only explaining factor for the inverse relationships observed.

Table 1. Hazard ratios for all-cause and cardiovascular mortality

Blood pressure indices	All-cause mortality HR (95%CI)	Cardiovascular mortality HR (95%CI)
Systolic pressure		
Model 1	0.83 (0.76-0.90)	0.83 (0.72-0.94)
Model 2	0.83 (0.75-0.90)	0.82 (0.72-0.93)
Model 3	0.83 (0.75-0.90)	0.82 (0.71-0.93)
Diastolic pressure		
Model 1	0.82 (0.69-0.97)	0.88 (0.68-1.13)
Model 2	0.79 (0.67-0.93)	0.87 (0.67-1.12)
Model 3	0.80 (0.68-0.95)	0.86 (0.67-1.12)
Pulse pressure		
Model 1	0.81 (0.72-0.90)	0.78 (0.66-0.91)
Model 2	0.81 (0.73-0.90)	0.78 (0.66-0.92)
Model 3	0.80 (0.72-0.90)	0.78 (0.66-0.91)

Increased protein intake is associated with uncontrolled blood pressure evaluated by 24-h ambulatory blood pressure monitoring in type 2 diabetes

M.J. Azevedo, C.B. Mattos, C.K. Kramer, T. de Paula, I.B. Ferreira, S.F. Tonding, J.L. Gross;

Endocrinology Division, Hospital de Clinicas de Porto Alegre, Universidade Federal do Rio Grande do Sul, Brazil.

Background and aims: Dietary intervention is an important component of hypertension management. However, evidence for dietary recommendation in patients with type 2 diabetes came from studies in non-diabetic individuals and evaluated only office blood pressure (BP) levels. Ambulatory blood pressure monitoring (ABPM) allows evaluation of BP homeostasis abnormalities not detected in office setting which have been associated with diabetic chronic complications. The aim of the present study was to analyze possible associations of usual diet with BP homeostasis in patients with type 2 diabetes. **Material and methods:** In this cross-sectional study 124 outpatients with type 2 diabetes (mean age: 62.4 years; mean diabetes duration: 12 years; 54% women; white ethnicity 73.4%; 81.5% hypertensive on office measurements) and without dietary counseling during the previous six months had their daily intake assessed by 3-day weighed-diet records (Nutribase 2007-updated). Reliability of records was confirmed by 24-h urinary nitrogen output. BP was assessed by ABPM (Spacelabs 90207). Patients were divided into two groups

according their daytime BP records on ABPM: uncontrolled-BP (systolic BP \geq 135 mm Hg and/or diastolic BP \geq 85 mm Hg) and controlled-BP (systolic BP $<$ 135 mm Hg and diastolic BP $<$ 85 mm Hg).

Results: Patients with uncontrolled-BP ($n=81$) had higher office systolic BP [147.4 \pm 25.2 vs. 134.2 \pm 19.5 mm Hg, $P=0.004$] and urinary albumin excretion [UAE, median (interquartile range); 7.7(37) vs. 4.9(95) mg/24-h, $P=0.04$] as compared to those with controlled-BP ($n=43$). Concerning dietary intake, patients with uncontrolled-BP had higher intake of protein [% energy (%en)] than patients with controlled-BP (20.0 \pm 3.7 vs. 18.2 \pm 3.6 %en, $P=0.02$). Lower carbohydrate intake (46.5 \pm 6.7 vs. 49.0 \pm 6.9 %en, $P=0.07$), higher HbA1C (8.3 \pm 2.0 vs. 7.6 \pm 1.3%, $P=0.06$), and higher BMI (29.9 \pm 4.9 vs. 28.5 \pm 4.3 kg/m², $P=0.13$) occurred in those with uncontrolled-BP as compared with controlled BP group, but statistical significance was not reached. Protein intake was associated with a 13% increased chance for having uncontrolled-BP in univariate analysis (OR 1.13; 95%CI 1.019–1.260; $P=0.02$). This association remained in a multivariate logistic regression model adjusted for BMI, HbA1C, and UAE (OR 1.13; 95%CI 1.008–1.272; $P=0.03$). Considering protein sources, meat intake [median (interquartile range) = 2.6(1.6) vs. 2.0(1.1) g/kg; $P=0.04$] was increased in patients with uncontrolled-BP, with a linear increase in the proportion of patients with uncontrolled-BP throughout quintiles of protein consumption (P for trend=0.04). Meat intake also had a linear association with 24-h systolic BP in a multivariate linear model, adjusted for BMI, HbA1c, and UAE (adjusted R² 25%; $P=0.02$). No association of ABPM measurements with carbohydrate intake was demonstrated.

Conclusion: Increased protein intake, especially from meat sources, was associated with an increased chance of having high ABPM values in patients with type 2 diabetes. Further studies are needed to clarify the role of reducing meat intake in hypertension management in patients with type 2 diabetes.

Tonometric ambulatory blood pressure measurements are reliable and improve hypertension diagnostics in patients with type 1 diabetes

S. Theilade, M. Lajer, C. Joergensen, F. Persson, P. Rossing;
Steno Diabetes Center, Gentofte, Denmark.

Background and aims: Blood pressure control is paramount in clinical management of type 1 diabetes (T1DM). A novel approach to blood pressure measurements is a tonometric technique, where a device (Bpro) captures radial pulse wave reflection and calculates brachial arterial blood pressure (BP). Tonometric BP measurements allow for more frequent and potentially more reliable BP measurements than cuff-based ambulatory (AMBP) measurements due to less discomfort and less anticipation BP rise in connection with BP measurements. The diagnosis of hypertension is often based on office blood pressure (OBP) rather than AMBP measurements. We suggest that OBP is suboptimal in hypertension diagnostics. In this study we investigate if a tonometric device is applicable and reliable in patients with T1DM, and whether OBP is reliable in hypertension diagnostics in T1DM.

Materials and methods: In a cohort of 24 Caucasian patients with diabetes we compared tonometric BP measurements with Bpro to a conventional, cuff-based device (Takeda TM2421). Patients were seen twice within 2 weeks. At visit 1, 15 minutes rest was followed by three Takeda measurements and 2 minutes continuous Bpro BP measurements. At both visits AMBP measurements were recorded using the Bpro. In a different cohort we included 326 Caucasian T1DM patients, 178 men (55%), aged (mean \pm SD) 54 \pm 13 years. Normoalbuminuria was present in 160 patients, whereas 166 patients had micro- or macroalbuminuria (>30 mg/24h), with creatinin levels of (mean \pm SD) 73 \pm 14 and 126 \pm 51 μ mol/l, respectively. All had been regularly attending clinical controls and were randomly selected for AMBP with a Bpro. Mean OBP was calculated from cuff-based BP measurements at three separate office visits $<$ 1 year prior to AMBP. AMBP and OBP values \geq 130/80 mmHg were classified as hypertension (acc. to ADA guidelines). Patients with normal OBP, but elevated AMBP were classified as masked hypertensives, and patients with elevated OBP, but normal AMBP were classified as white coat hypertensives.

Results: Validation: At visit 1, Takeda BP values (mean \pm SD) were 136 \pm 19/72 \pm 8 mmHg vs. Bpro values of 138 \pm 19/78 \pm 8 mmHg. The visit 1 Bpro AMBP was 132 \pm 20/76 \pm 9 mmHg vs. 131 \pm 13/75 \pm 9 mmHg at visit 2. Correlations between the Takeda and Bpro systolic and diastolic BP were $r=0.86$ and 0.65 , respectively ($p<0.001$). The mean differences (\pm SD) between devices were 1.9 \pm 10 and 5.5 \pm 6.6 mmHg for systolic and diastolic BP, respectively. Comparison of Bpro systolic and diastolic AMBP at visit 1 and 2 showed no difference in mean BP ($p=0.81$ and $p=0.76$, respectively). Neither mean day BP, mean

night BP nor mean dipping were statistically different ($p>0.40$) between the two visits. Evaluation: OBP values were (mean \pm SD) 136 \pm 14/76 \pm 8 mmHg vs. AMBP 129 \pm 15/76 \pm 10 mmHg. Fifty-nine patients (18%) were normotensive and 153 (47%) had sustained hypertension with both AMBP and OBP. White coat hypertension was present in 82 (25%) and masked hypertension in 32 (10%) patients. Thus, 65% were diagnosed correctly by OBP, assuming AMBP reveals the correct BP. Overall, 185 patients (57%) did not reach target BP of $<$ 130/80 mmHg, as they had either sustained (47%), or masked (10%) hypertension.

Conclusion: In patients with diabetes tonometric BP measurements are comparable to cuff based measurements, and tonometric AMBP measurements are reproducible. In T1DM, AMBP is necessary to diagnose hypertension in 35% of patients. Despite regular follow-up, the majority of patients did not reach target BP.

Longer term effect of pregnancy induced hypertension on chronic kidney disease and hypertension: a case-control study

K. Jahan¹, F. Jebunnesa², S. Sultana³, H. Chowdhury³, N. Sultana⁴, L. Ali²;

¹Dept of Gynecology and Obstetrics, Dhaka Medical College, ²Dept of Biochemistry and Cell Biology, Bangladesh Institute of Health Sciences (BIHS), ³Dept of Biostatistics, Bangladesh Institute of Health Sciences (BIHS), ⁴Dept of Biochemistry and Cell Biology, BIRDEM, Dhaka, Bangladesh.

Background and aims: Pregnancy Induced hypertension (PIH) with its proteinuric (PE) and nonproteinuric (GH) subtypes are known to be a major cause of maternal and fetal morbidity and mortality. In addition, PIH is claimed to create greater risk of hypertension (HTN) and chronic kidney diseases (CKD) at later life of the women. The nature and extent of HTN and CKD along with the interrelation of the two disorders are still not fully settled. The present study was designed to explore what proportion of women with history of PIH develop HTN and CKD in later stages after delivery and, at the same time, to study the interrelation of HTN and CKD with their socio-demographic, anthropometric and biochemical risk factors.

Materials and methods: Under an observational case-control design 133 women with previous history of PIH [the PIH group; Age (yrs), Median (range) 31 (25–45), and BMI (kg/m², (Mean \pm SD) (25.2 \pm 2.1)] were compared with 113 women without history of PIH (Non-PIH group), Age (yrs) Median (range) 34 (25–45), and BMI [(kg/m², Mean \pm SD) (25.8 \pm 2.9)] for the development of HTN (SBP $>$ 130 mmHg; DBP $>$ 90 mmHg; or MBP $>$ 105 mmHg) and CKD (as measured by total urinary protein and elevated UPCR). Clinical and anthropometric parameters were measured by standard techniques, lipids were measured by enzymatic-colorimetric method, urinary total protein by pyrogallol red method, urinary protein by strip method and urinary creatinine was measured by alkaline picrate method.

Results: Out of the 133 subjects in the PIH group 43(32.3%) developed HTN and 41 (30.8%) developed CKD. In the Non-PIH group 17(15%) developed HTN and 16 (14.2%) developed CKD. SBP, DBP and MBP, all were significantly higher in the PIH compared to the Non-PIH group. PIH subjects had 4 times higher chance of developing HTN (Odds Ratio 4.2). In parallel to the findings on HTN the PIH group showed a significantly higher proportion of CKD [Proteinuric 10 (7.5%)]. Both urinary total protein and urinary protein-creatinine ratio were significantly higher in the PIH group as compared to the Non-PIH group. The PIH subjects had almost 3 times chance of developing CKD compared to the Non-PIH group. A significant correlation of MBP was found with UPCR, Tchol and serum uric acid. On the other hand UPCR was also correlated with SBP. On logistic regression MBP had a positive association with UPCR and Uric Acid.

Conclusion: About one-third of women with a previous history of PIH develop HTN in later life and the proportion is two times higher and the risk is 4 times more than that in the Non-PIH counterparts. About 8% of women with previous history of PIH develop chronic kidney disease in later life and the proportion is 5 times higher to develop and they are almost 3 times more vulnerable than that in the non-PIH group.

Sodium glucose co-transporter-2 (SGLT2) inhibitor, PF04971729, reduces blood pressure and body weight in spontaneously hypertensive rats (SHR)

D.R. Knight, N.B. Amin, D.A. Beebe, R.L. Schroeder, A.H. Smith;
CVMED Research Unit, Pfizer, Inc., Groton, USA.

Background and aims: Studies suggest that SGLT2 inhibition results in a favorable effect on blood pressure (BP) in type 2 diabetics with mild hypertension and obesity. Since SGLT2 inhibition not only reduces hyperglycemia and body weight (BW), but also produces diuresis via an increase in urinary glucose excretion (UGE), it would be important to determine if SGLT2 inhibition reduces BP in a hypertensive model without the hyperglycemia and obesity associated with type 2 diabetes. Thus, the goal of this study was to evaluate the BP lowering effects of a new, highly potent and selective SGLT2 inhibitor, PF04971729, in the lean, euglycemic SHR model of hypertension.

Materials and methods: Age-matched (13 week old), male SHR were previously instrumented using aseptic techniques to measure aortic BP via telemetry. After recovery from surgery and acclimation to telemetry housing, the rats were allocated into two study groups (control and PF04971729-treated, $n = 8$ /group) based on BW and systolic BP. PF04971729-treated SHR were paired to match the amount of chow consumed per day by the control group. PF04971729 was delivered in an admixture (0.5 mg PF04971729/g chow) to produce a near-maximal increase in UGE. Blood pressure measurements over 24 h were obtained at baseline (Day 0) and after 27 days of treatment. All rats were then placed in metabolic cages for 24-h urine collection followed by blood sample collection.

Results: All data are Mean \pm SEM. Statistical significance ($p < 0.05$) vs baseline or control group was calculated using ANOVA. Baseline BP values were similar between the control and PF04971729-treated hypertensive SHR (see table). At the end of treatment, PF04971729 increased ($p < 0.05$) UGE to 3636 ± 111 mg/24 h compared to the control group (7 ± 3 mg/24 h); however, plasma glucose levels (140 ± 11 mg/dl) were not different compared to the control group (147 ± 21 mg/dl) in the euglycemic SHR. PF04971729 (vs control) increased ($p < 0.05$) urine volume to 42 ± 1 vs 14 ± 1 mL/24 h, increased ($p < 0.05$) hematocrit to 53 ± 1 vs 49 ± 1 %, and increased ($p < 0.05$) plasma renin activity to 21 ± 3 vs 7 ± 1 ng/ml/h, consistent with a diuretic effect. On day 27, PF04971729 significantly lowered systolic BP and mean BP compared to baseline and control group; the decrease in diastolic BP in the PF04971729-treated rats did not reach statistical significance (see table). Heart rate was slightly lower (-9 ± 4 beats/min) in the control group but significantly ($p < 0.05$) lower (-49 ± 7 beats/min) in the PF04971729-treated SHR. In contrast to the control group, PF04971729 by day 27 caused a 12 ± 1 % loss ($p < 0.05$) in BW from baseline (307 ± 4 g).

Conclusion: This study for the first time demonstrates a nonclinical BP lowering with SGLT2 inhibition in a lean, euglycemic SHR model of hypertension. The BP lowering was associated with significant diuretic effects that may be exaggerated by the loss of BW in the pair-fed SHR. The magnitude of BP lowering over 24 h with PF04971729 in hypertensive, type 2 diabetic patients is under clinical evaluation.

Effects of PF04971729 on 24h BP measurements in SHR

	Control (n=8)		PF04971729 (n=8)	
	Day 0	Day 27	Day 0	Day 27
Systolic BP (mmHg)	166 \pm 2	170 \pm 5	167 \pm 2	151 \pm 5*†
Diastolic BP (mmHg)	111 \pm 2	115 \pm 5	110 \pm 2	101 \pm 5
Mean BP (mmHg)	138 \pm 2	143 \pm 5	138 \pm 2	125 \pm 5*†

Mean \pm SEM; * $p < 0.05$ vs baseline; † $p < 0.05$ vs control (ANOVA)

Blood pressure lowering effects of the direct renin inhibitor aliskiren in patients with diabetes: a pooled analysis of 16 randomised trials

J.R. Sowers¹, T. Severin², M. Maboudian³, C. Cherif-Papst³, D.H. Zappe²;
¹School of Medicine, Division of Endocrinology, Diabetes and Metabolism, Columbia, USA, ²Novartis Pharma AG, Basel, Switzerland, ³Novartis Pharmaceuticals Corporation, East Hanover, USA.

Background and aims: Diabetes mellitus and hypertension is typically associated with activation of the renin angiotensin aldosterone system (RAAS) leading to poorer clinical outcomes compared to a general hypertensive pop-

ulation. The aim of this pooled analysis was to evaluate the blood pressure (BP) lowering efficacy of aliskiren monotherapy in hypertensive patients with diabetes.

Materials and methods: Data was pooled from pooled from 16-randomized, double-blind clinical trials to evaluate the blood pressure (BP) lowering efficacy of aliskiren monotherapy (150-300 mg) over 8-12 wks in 879 hypertensive patients with diabetes.

Results: The mean baseline values for the total population ($n = 10875$) and the patients with diabetes ($n = 1672$) were as follows; systolic BP $154.3 \pm 12.0/156.3 \pm 11.8$ mmHg; diastolic BP $97.4 \pm 6.5/96.3 \pm 7.2$ mmHg; $56.7 \pm 12.1/60.5 \pm 10.9$ yrs (57/60 % male), BMI 29.4 ± 5.9 ($37\% \geq 30$ kg/m²)/ 31.1 ± 6.0 ($50\% \geq 30$ kg/m²); eGFR, $88.8 \pm 20.8/88.1 \pm 23.3$ ml/min and fasting glucose $5.9 \pm 1.5/7.8 \pm 2.5$ mmol/L. The patients with diabetes in response to aliskiren monotherapy had significant dose-related reductions in systolic and diastolic BP which were similar to the overall patients (Table). However the systolic BP lowering effect of aliskiren was similar between the diabetic patients with fasting glucose levels ≥ 7 mmol/L (-15.2 ± 13.1 mmHg; $n = 420$) and those below 7 mmol/L (-14.3 ± 14.0 mmHg; $n = 332$). Baseline plasma renin activity and aldosterone levels for patients with diabetes (0.53 ng/ml/h; 169 pmol/L) were similar to those of the overall hypertensive patients (0.57 ng/ml/h; 171 pmol/L).

Conclusions: The BP lowering results in hypertensive patients with diabetes demonstrated that despite greater challenge for these patients to reach a target BP goal their responsiveness to direct renin inhibition with aliskiren monotherapy was similar to the overall hypertensive patients in clinical trials. Further, the antihypertensive response to aliskiren in patients with diabetes was not influenced by baseline glycemic status or activation of the renin angiotensin system. The data also suggest that the effectiveness of aliskiren is not associated with elevations in plasma renin in patients with diabetes.

Mean change in blood pressure

Treatment	All patients (n)	Patients with diabetes (n)
Placebo	SBP -6.1 \pm 12.9 (1728)	-6.8 \pm 14.2 (151)
	DBP -5.45 \pm 8.2	-5.7 \pm 8.1
Aliskiren 150 mg	SBP -13.1 \pm 13.1 (2613)	-12.7 \pm 13.7 (309)
	DBP -9.0 \pm 8.2	-7.8 \pm 8.7
Aliskiren 300 mg	SBP -16.6 \pm 13.7 (3310)	-15.2 \pm 13.1 (575)
	DBP -10.65 \pm 8.4	-11.6 \pm 8.3

Data shown are mean \pm SD changes from baseline in SBP and DBP (mmHg). SBP, systolic blood pressure; DBP, diastolic blood pressure.

Effect of bariatric surgery on the mechanisms involved in obesity-related hypertension: the renin-angiotensin-aldosterone and sympathetic nervous systems and endothelial dysfunction

L. Flores¹, J. Vidal¹, I. Nuñez², J. Viaplana³, R. Gilabert², E. Esmatjes⁴;
¹Obesity Unit, Department of Endocrinology and Nutrition, Hospital Clinic, ²Diagnostic Imaging Center, Hospital Clinic, ³Institut d'Investigacions Biomèdiques Augusti Pi i Sunyer, Hospital Clinic, ⁴Diabetes Unit, Department of Endocrinology and Nutrition, Hospital Clinic, Barcelona, Spain.

Background: The activation of the renin-angiotensin-aldosterone system (RAAS), the sympathetic nervous system (SNS), endothelial dysfunction and hyperleptinemia has been implicated in the pathogenesis of obesity-related hypertension (HT).

Aim: We evaluated the effect of significant and sustained weight loss obtained by bariatric surgery (BS) on blood pressure (BP) and their main mechanisms of regulation.

Methods: Patients with severe obesity and documented HT who underwent laparoscopic BS (bypass gastric or sleeve gastrectomy) were studied. Patients were evaluated before BS and 4 and 12 months post-operatively. Antihypertensive treatment was withdrawn one week before each evaluation. Anthropometric data were collected and BP (24-h ambulatory BP measurement) assessment and blood samples were analysed for RASS [plasma renin activity (PRA), aldosterone, angiotensin II and angiotensin converting enzyme], SNS (metanephrine, normetanephrine and noradrenaline), insulin and leptin values. Endothelial function was determined by endothelial-dependent flow-mediated vasodilatation on the brachial artery and the ratio of the intra-

abdominal visceral fat area to the subcutaneous fat area (V/S ratio) was calculated using an abdominal scanner.

Results: Twenty-five patients were studied; 16 females, aged 51 (37–64) years, with HT evolution of 6 (1–20) years and excess body weight of 55 (36–76) kg. Twelve months after BS: the BMI decreased from 46 to 32 Kg/m²; excess body weight loss was 69 (16) %; 64% patients had complete resolution of HT while 32 % patients had improvement; 24-h (systolic -17 (14)/diastolic -6 (11) mmHg), daytime and night-time BP values decreased significantly. The PRA (0.26 to 0.19 ng/mL*h), aldosterone (5.5 to 3.2 ng/dl), nor-adrenaline (117 to 91 pg/mL), insulin (33 to 10 mU/L) leptin (67 to 20 ng/ml) and V/S ratio (0.39 to 0.24 cm²) also significantly decreased ($p < 0.05$). We observed a direct relationship between decrease in 24 h and night-time systolic BP and reduction of nor-adrenaline ($r^2 = 0.22$, $p = 0.03$ and $r^2 = 0.39$, $p = 0.003$, respectively). No significant differences were observed in endothelial-dependent flow-mediated vasodilatation after BS.

Conclusion: Weight loss after BS is associated with a reduction in BP and RAAS and SNS activity in hypertensive obese patients.

Prorenin stimulates retinal endothelial cell proliferation: implications for diabetic retinopathy

T. Zhu¹, A.G. Miller¹, K.J. Binger¹, D.J. Campbell^{2,3}, J.L. Wilkinson-Berka¹;

¹Immunology, Monash University, ²St. Vincent's Institute of Medical Research, ³University of Melbourne, Australia.

Background and aims: The renin-angiotensin system (RAS) contributes to the development of diabetic retinopathy (DR), one of the most feared complications of diabetes. Pre-clinical studies and clinical trials such as Diabetic REtinopathy Candesartan Trial (DIRECT) have reported that type 1 angiotensin receptor blockade (ARB) attenuates vasculopathy in DR. Despite these findings, ARB does not provide full protection in DR, suggesting the involvement of other mechanisms. Prorenin, the inactive precursor of renin, which initiates the RAS, is present at increased concentration in plasma and vitreous fluid of patients with proliferative DR. However, whether prorenin itself contributes to retinal endothelial cell proliferation is unknown. This study aims to determine whether prorenin influences retinal endothelial cell proliferation and whether this involves the (pro)renin receptor [(P)RR].

Materials and methods: The proliferation of primary bovine retinal endothelial cells (BREC) was measured following treatment with a range of concentrations of prorenin (0.02 to 20nM). To determine if prorenin's influence on BREC proliferation involved the type 1 angiotensin receptor or renin, BREC were co-incubated with prorenin (2nM) plus candesartan (10μM) or the renin inhibitor aliskiren (10μM). Real-time PCR was performed to measure the expression of the angiogenic factors; vascular endothelial growth factor (VEGF), VEGF Receptor 2 (VEGFR2) and tyrosine kinase with immunoglobulin-like and EGF-like domains 2 (Tie2), and the (P)RR, after a time course of 2nM prorenin stimulation.

Results: Prorenin promoted BREC proliferation by $43.74 \pm 11.36\%$ ($p < 0.05$), whereas candesartan alone had no effect, and aliskiren alone reduced proliferation by $54.15 \pm 0.29\%$ ($p < 0.001$), compared to untreated control. Candesartan pretreatment had no effect on the stimulation of BREC proliferation by prorenin. Although aliskiren pretreatment reduced BREC proliferation, subsequent addition of prorenin to aliskiren-treated BREC increased proliferation above that seen with aliskiren alone. Prorenin increased VEGF, VEGFR2, Tie2 and (P)RR mRNA levels (1.1 to 1.3 fold, $p < 0.05$) in a time dependent manner (between 2 and 8 hours).

Conclusion: This study demonstrated that prorenin, independently of type 1 angiotensin receptor activity or renin activity, stimulated pathological events associated with the development of DR such as endothelial cell proliferation and the expression of angiogenic factors. The finding that (P)RR mRNA levels are altered, suggests that prorenin may mediate its effects on retinal vascular proliferation via the (P)RR.

Anti-apoptotic effect of angiotensin-II receptor blockade in human retinal pericytes cultured in diabetic-like conditions

E. Berrone, E. Beltramo, S. Tarallo, M. Porta;

Dept. Internal Medicine, University of Turin, Italy.

Background and aims: Diabetic retinopathy is characterized by damage to the retinal microvasculature. Capillary degeneration, which includes thickening of the basement membrane and pericyte drop-out, begins early and, as it becomes more extensive, contributes to large areas of capillary non-perfusion characteristic of advanced diabetic retinopathy. Angiotensin II (Ang II) regulates several pathological events, including cell proliferation/hypertrophy, proinflammatory responses and extracellular matrix degradation. Elevated Ang II and/or increased sensitivity to Ang II have been etiologically associated with major vascular diseases. Most of the studies on the effects of Ang II on vascular cells, however, have been done on smooth muscle cells while an emerging role for Ang II in the modulation of retinal vascular cell function in diabetes has been recently postulated. Clinical studies have suggested that inhibitors of the renin-angiotensin system (RAS) may slow the progression of mild to moderate diabetic retinopathy. The objective of this study was to verify if the Ang II receptor blocker candesartan can act as an anti-apoptotic and protective factor for human retinal pericytes (HRP) in diabetic-like conditions, counteracting the negative effects of high glucose.

Materials and methods: Pericytes were kept alternatively in high (28 mM, HG) or normal (5.6 mM, NG) glucose at 48h intervals for 8 days (intermittent HG, intHG), with or without 10, 2, 1 or 0.2 μ M candesartan. Control cells were cultured in stable NG or HG. Apoptosis was determined by ELISA, as DNA fragmentation, proliferation by cell counts and BrdU incorporation. Senescence-associated lysosomal activity by β -galactosidase staining was performed as a biomarker for cellular aging and observed at the light microscopy. **Results:** Intermittent but not stable HG increased apoptosis in HRP (+52.5%, $p < 0.05$ vs NG), consistently with our previous findings showing that exposure to intermittent but not steadily high glucose increases apoptosis in human pericytes. Candesartan 1 and 0.2 μ M, added to intermittent HG, was able to normalize apoptosis (1 μ M candesartan: -30.3%, 0.2 μ M candesartan: -42.8% vs intHG, $p < 0.05$), while higher concentrations had no significant effects. Addition of candesartan seemed to have no influence on proliferation, but it was able to reduce intermittent high glucose-activated senescence.

Conclusion: Candesartan has a significant anti-apoptotic and anti-senescence effect on human retinal pericytes grown in diabetic-like conditions. Further studies are necessary to better understand the mechanisms through which it works, in particular the signalling pathways involved and/or influenced by the RAS.

FAD286, an aldosterone synthase inhibitor, reduces retinal neovascularisation

D. Deliyanti¹, A.G. Miller¹, K.J. Binger¹, G. Tan¹, L. Sutton¹, M. Jayamanne², T. Rupasinghe², D.L. Tull², M. McConville², J.L. Wilkinson-Berka¹; ¹Immunology, Monash University, Melbourne, ²Metabolomics Australia, The University of Melbourne, Parkville, Australia.

Background and aims: Blockade of the type 1 angiotensin receptor (ARB) is a potential treatment for microvascular disease in diabetic retinopathy. We previously identified that inhibition of the mineralocorticoid receptor (MR) also reduces vasculopathy in experimental diabetic retinopathy. However, it remains to be determined whether aldosterone or corticosterone, which both bind to the MR, are responsible for MR stimulation on retinal neovascularization. The aim of this study was to determine if inhibition of aldosterone with the aldosterone synthase inhibitor, FAD286, reduces retinal neovascularization, and whether it is as effective as ARB. Additionally, we evaluated the cellular source of aldosterone synthase in retina.

Materials and methods: Oxygen-induced retinopathy (OIR) was induced in Sprague Dawley rats (80% O₂, 22hrs/day) from postnatal days (P) 0 to P11, followed by 7 days in room air. Control rats were always in room air. FAD286 (30mg/kg/day), the ARB valsartan (10mg/kg/day) or a combination of FAD286+valsartan was administered between P12 to P18. Primary cultures of rat retinal microglia, rat glia, rat ganglion cells, bovine retinal endothelial cells and bovine retinal pericytes were studied.

Results: In OIR, FAD286 reduced pre-retinal neovascularization and neovascular tufts by approximately 89% and 67% respectively compared to untreated OIR, and to a similar extent as valsartan and combination treatment. In OIR, retinal mRNA and protein levels of the potent angiogenic factor, vascular endothelial growth factor, were increased by 1.7 and 4.74 fold respectively compared to control ($P < 0.05$), and reduced to a similar extent with FAD286, valsartan and combination treatment. In OIR, FAD286 reduced the retinal mRNA levels of the inflammatory mediators: tumor necrosis factor- α , intercellular adhesion molecule-1, vascular adhesion molecule-1 and monocyte chemoattractant molecule-1 to a similar extent as valsartan and combination treatment ($P < 0.05$ to OIR). In retina, FAD286 reduced both aldosterone synthase mRNA and aldosterone levels, whereas hydrocorticosterone levels were unchanged. In vitro, microglia and ganglion cells were identified as the major sources of aldosterone synthase mRNA and all cell types expressed MR mRNA. In OIR, the density of microglia (Iba1 immunolabelling) was increased in OIR (2.54 ± 0.33) compared to controls (0.21 ± 0.02), and reduced to a similar extent with FAD286 (1.24 ± 0.18 , $P < 0.05$ to OIR) and other treatments.

Conclusion: The finding that inhibition of aldosterone production per se, is equally effective as ARB in ameliorating retinal neovascularization, suggests that aldosterone may be needed to be considered when evaluating treatments for diabetic retinopathy that involve blockade of the renin-angiotensin system. The localization of aldosterone synthase to retinal microglia and ganglion cells suggests that these cell types participate in the neovascular response induced by aldosterone.

Effects of atorvastatin and insulin in the retina of an animal model of type 2 diabetes with hyperlipidaemia

R. Fernandes¹, C. Bento², C.M. Sena³, R.M. Seica³, P. Pereira²; ¹Laboratory of Pharmacology and Experimental Therapeutics, IBILI/FMUC, ²COVS, IBILI/FMUC, ³Laboratory of Physiology, IBILI/FMUC, Coimbra, Portugal.

Background and aims: Insulin resistance, a key feature of obesity, the metabolic syndrome and T2D, results in a variety of metabolic and vascular abnormalities. Endothelial dysfunction is intricately related to insulin resistance through the parallel stimulatory effects of insulin on glucose disposal in metabolic tissues. Perturbations characteristic of insulin resistance, including dyslipidaemia, inflammation and oxidative stress, may together contribute to disrupt the structural or functional integrity of the retina endothelium. The purpose of this study is to investigate the retinal cells damage in diabetic and high-fed animal models and elucidate the potential mechanisms underlying the benefits of therapy with atorvastatin or insulin.

Materials and methods: The proteasome activities were assessed using fluorogenic substrates in non-diabetic animals (Wistar rats), untreated Goto-Kakizaki rats (diabetic rats), high-fat fed GK rats (fed with atherogenic diet only for 4 months, treated with insulin or atorvastatin for the last month). Production of oxygen reactive species was determined by immunofluorescence in frozen retina sections using dihydroethidium, in the different groups of animals. Protein levels of ubiquitin conjugates, free ubiquitin, E1, I κ B and NF- κ B were determined by Western Blotting. Cell death was determined by evaluation of the levels of Bax, Bcl-2 and caspase-3 by immunofluorescence and immunoblot analysis. Data were expressed as mean \pm SEM. ANOVA followed by Bonferroni's post hoc test. $P < 0.05$ was considered statistically significant.

Results: Diabetes and atherogenic diet significantly induced an increase in the production of superoxide anion in retinas (from 100% to $158 \pm 12.5\%$ and $195 \pm 13.6\%$, respectively). Our data indicates also a significant decrease in chymotrypsin-like (to $39.9 \pm 0.02\%$) and post-glutamyl peptide hydrolytic-like (to $75.1 \pm 0.01\%$) activities and unchanged tryptic-like activity when the diabetic animals were fed with atherogenic diet. Statins significantly reverted the levels of oxidative stress and recovered the proteasome activities to similar levels of control rat retinas. The atherogenic fat diet induced a significant decrease in the high molecular weight ubiquitin conjugates (to $58.3 \pm 5.9\%$) paralleled with an increase in free ubiquitin. This may occur as a result of degradation of E1-ubiquitin activating enzyme by calpains, being a limiting step in the formation of the ubiquitin protein conjugates. Diabetes increases the ratio of Bax/Bcl-2 proteins. We also observed that atherogenic diet induced a hyperphosphorylation of Bcl-2 and its inactivation, leading to caspase-3 cleavage and cell death by apoptosis. Bcl-2 inactivation led to degradation of I κ B, allowing NF- κ B to enter the nucleus and induce gene expression.

Conclusion: Increased oxidative stress in diabetic retinas from animals with obesity leads to inactivation of the 20S proteasome activity and increased cell death by apoptosis. Atorvastatin monotherapy restores the retina cell function and significantly improves local oxidative stress in high-fat fed GK rats. Improved retinal cells function due to statins was at least partially to the ubiquitin proteasome pathway restoration, and represents a pharmacological approach to prevent some of the complications associated with diabetic retinopathy.

S-nitrosoglutathione ameliorates the early marker of diabetic retinopathy through oxidative status balance

J.M. Lopes de Faria, K.C. Silva, M.A.B. Rosales, M.G. Oliveira, J.B. Lopes de Faria; University of Campinas, Brazil.

Background and aims: The chemistry associated with the production of nitric oxide (NO) in biological systems provides arguments from which the diverse functions of NO may be interpreted. NO is a readily diffusible, short-lived molecule produced by the action of NO synthase (NOS) on L-arginine. In the nervous system, NO is a neurotransmitter and can act both intracellularly as a second messenger and extracellularly as a conveyor of information between cells and as a neuromodulator. On the other hand, NO signaling in endothelial cells regulates vascular permeability and blood flow, and the uptake and response to therapeutic compounds. S-nitrosoglutathione (GSNO), a possible carrier of NO, may extend the *in vivo* actions of locally produced NO. GSNO has been shown to be several-fold more potent than reduced

glutathione (GSH) against oxidative stress. N-nitrosation of amines to form N-nitrosamines (RNNOs) has been studied mainly in the context of carcinogenesis with no information in diabetic retinal disease. The aim of this study was to investigate the efficacy of GSNO topically (eye drop) in preventing the early retinal change in an *in vivo* and *in vitro* study.

Materials and methods: 4-week-old spontaneously hypertensive rats (SHR) were rendered diabetic by intravenous injection of streptozotocin (50 mg/kg), the control rats received only citrate buffer. Diabetic SHR rats were randomized to receive no treatment or treatment with GSNO topically twice a day (600 nM) for 20 days. *In vitro* studies were performed with human retinal pigment epithelial cell (ARPE-19) cultured in normal glucose (NG; 5mM), high glucose (HG; 30mM) and high glucose (HG; 30mM) plus GSNO treatment with 1, 10 and 100nM, 1 and 10μM for 24 hours after MTT cytotoxicity assay. Intracellular reactive oxygen species (ROS) production was assessed by 2',7'-dichlorofluorescein diacetate (H₂DCFDA). The results were compared by Analysis of Variance (ANOVA) followed by Fisher's protected least significant difference test.

Results: As expected, body weight was lower and glycaemia was greater in diabetic SHR's than in non-diabetic rats ($p<0.0001$); the systolic blood pressures were equal in all studied groups. The early molecular marker of diabetic retinopathy (DR), evaluated through glial reaction by expression of glial fibrillary acidic protein (GFAP), was significant increased in diabetic SHR compared with control SHR rats ($p=0.005$). The eye drop treatment in diabetic SHR prevented this increment. In ARPE-19 cells, there was an increasing in ROS production under HG compared with NG ($p=0.02$) and the treatment with GSNO (1, 10 and 100nM) reestablished to normal levels.

Conclusion: Topical treatment with GSNO eye drop prevented the increase of GFAP in diabetic rats and *in vitro* abolished the ROS production in ARPE-19 under HG. The molecular mechanisms of GSNO actions in the diabetic retinas are being assessed in *in vitro* studies.

HM-VN118, a herbal medicine, inhibits the development of diabetic retinopathy and retinal AGEs accumulation in spontaneous diabetic Torii rats

J. Kim, C.-S. Kim, E. Sohn, J. Kim;

Diabetic Complications Research Center, Korea Institute of Oriental Medicine, Daejeon, Republic of Korea.

Background and aims: Diabetes alters the structure and function of most cell types in the retina, including the vasculature and neural network. The loss of retinal capillary cell and neuronal cell is a hallmark of diabetic retinal changes. Advanced glycation end products (AGEs) are believed to contribute to retinal cell loss in diabetic retinopathy. The aim of this study was to investigate the potential preventive effect of HM-VN118, a herbal medicine, on diabetic retinopathy in spontaneous diabetic Torii (SDT) rat, and animal model of type II diabetes.

Materials and methods: Twenty five week-old male SDT rats were treated with HM-VN118 (100 and 250 mg/kg body weight) once a day orally for 17 weeks. AGEs accumulation, pericyte loss, blood retinal barrier breakage and ganglion cell injury were investigated in retinas from SDT rats.

Results: Vehicle-treated SDT rats exhibited hyperglycaemia and diabetic retinopathy. However, the treatment of HM-VN118 decreased significantly AGEs levels in retinal tissues ($p<0.01$ vs vehicle). In fluorescein angiography, the changes of retinal vasculature, such as fluorescein leakage and vessel narrowing were significantly reduced in SDT rats treated with HM-VN118. In addition, the retinal vascular disorders such as pericyte loss and acellular capillary formation were highly observed in SDT rats, but in SDT rats treated with HM-VN118, these changes were observed rarely. Similarly, diabetes-induced microvascular and neuronal cell apoptosis was also reduced in HM-VN118-treated SDT rats ($p<0.05$ vs vehicle).

Conclusion: These results suggest that HM-VN118 is useful in inhibiting the AGEs accumulation in diabetic retinas and may have therapeutic potential in the treatment of diabetic retinopathy.

Figure 1. Effects of HM-VN118 on retinal vascular hyperpermeability (upper panels), microvascular cell loss (middle panels) and AGEs accumulation (low panels) in SDT rats. In fluorescein angiography, white arrow indicates the vascular leakage. In PAS staining, black arrowhead and arrow indicate acellular capillary and migrating pericyte (magnified inset), respectively. Retinal AGEs accumulation (red) was observed in SDT rats.

Green tea polyphenols protect retinal cells in high glucose condition

K.C. Silva, M.A.B. Rosales, A.M. Faria, J.B. Lopes de Faria, J.M. Lopes de Faria;

Faculty of Medical Sciences, State University of Campinas, Brazil.

Background and aims: In our previous studies, we have demonstrated that green tea polyphenols (GTPs) attenuate the early changes in the retina from experimental diabetic rats, such as glial fibrillary acidic protein (GFAP), tight junction occludin and nitrotyrosine expression, blood retinal barrier breakdown and retinal function evaluated by electroretinogram. The ARPE-19 cell line is a human retinal pigment epithelium (RPE) and has been used in studies to evaluate not only the outer blood retinal barrier (BRB) but also the retinal neuroprotection since these cells exhibit glutamate transporters. Glial cells (especially Muller cell) have a central role in the homeostasis in the retina including maintenance of BRB and the neural retinal elements from the excessive stimulation of neuronal NMDA-sensitive glutamate receptors. Thus, the mechanisms to remove glutamate from the extracellular space are required for efficient maintenance of a healthy retina. The aims of this study were to investigate the possible mechanisms involved into the protective effects of GTPs on Muller and retinal pigment epithelium cells (ARPE-19) exposed to high glucose.

Materials and methods: For these studies, we used ARPE-19 and Muller cells. The cells were exposed to normal glucose (NG; 5mM), high glucose (HG; 30mM) in presence or absence of GTPs treatment and high glucose (30mM) with epigallocatechin gallate (EGCG) for 24 hours. In ARPE-19, the cytotoxicity was determined by MTT assay for treatments with GTPs and EGCG. 100 μg/ml was selected for GTPs and 50, 25 and 10μM for EGCG for the experiments. The total intracellular reactive species (ROS) was determined by 2',7'-dichlorodihydrofluorescein diacetate (H₂DCFDA) method. The expression on cell lysates of EAAC1 (glutamate transporter) was determined by western blot. In Muller cells, we analyzed the expression of GFAP by immunofluorescence and glutamate transporter (Glast) and glutamate receptor (NMDAR1) by Western blot. The results were compared by Analysis of Variance (ANOVA) followed by Fisher's protected least significant difference test.

Results: In ARPE-19 cells, cultured under HG for 24 hours, there was an increasing in ROS production compared with NG ($p<0.0001$). The presence of GTPs prevented this abnormality ($p=0.001$); similar findings were observed in presence of EGCG under HG condition ($p=0.001$). The protein expression of EAAC1 was increased in HG and reversed with GTPs ($p<0.05$). In Muller cells, the levels of GFAP evaluated by immunofluorescence were increased in HG compared with NG and the treatment with GTPs abolished this effect. Glutamate transporter expression and its receptor decreased in HG ($p<0.05$) and the treatment with GTPs reestablished ($p<0.05$).

Conclusion: GTPs prevented the ROS and EAAC1 increments in ARPE-19 cells. In the Muller cells, there was a significant reestablishment of glutamate transporter/NMDAR1 status. These findings may be an indicative that GTPs protect either glial as epithelial retinal cells from the high glucose damage. Studies to identify the mechanisms of action of GTPs on different retinal cells in HG are being performed.

Polyphenol enriched cocoa protects the retinal function in experimental diabetes: an *in vivo* and *in vitro* study

M.A.B. Rosales, K.C. Silva, A. Papadimitriou, J.B. Lopes de Faria, J.M. Lopes de Faria;
Department of Internal Medicine, Faculty of Medical Sciences, State University of Campinas (UNICAMP), Brazil.

Background and aims: A significant body of evidence demonstrates that moderate chocolate consumption could be part of a healthy diet has gained acceptance in past years based on the health benefits ascribed to selected cocoa components. It has been demonstrated flavonoid compounds found in foods, including epicatechins found in high-cocoa-solid chocolates, in the prevention and treatment of diabetic complications by antioxidant and anti-inflammatory properties. The mechanisms behind these effects are still under investigation. The blood-retinal barrier (BRB) is essential to maintaining the eye as a privileged site and is essential for normal retinal function and diabetic retinopathy (DR) is associated with early alterations of the BRB in its pathogenesis. The objective of this study was to investigate the effects of polyphenol enriched cocoa in neural retina and in BRB function in an experimental diabetic rat.

Materials and methods: Diabetes was induced by streptozotocin (60 mg/kg) in normotensive rats (WKY) with 10 week-old. The animals were divided into 4 groups, control and diabetic WKY treated with polyphenol enriched cocoa (190 mg/kg), and control and diabetic WKY with placebo (cocoa without polyphenols) by oral gavage daily. After 16 weeks, the animals were submitted to electroretinography (ERG) and then euthanized; the retinas were collected for protein extract and morphology. The *in vitro* study was performed with human retinal pigment epithelium cells line (ARPE-19) exposed to high glucose (30 mM) for 24 hours. The cytotoxicity of the polyphenol enriched cocoa on ARPE-19 cells was determined by MTT assay and 10 ng, 100 ng and 1 µg/ml were selected for the experiments. The total intracellular reactive species (ROS) was determined by 2',7'-dichlorodihydrofluorescein diacetate (H₂DCFDA) method.

Results: As expected, body weight was lower and glycemia was greater in diabetic WKY's than in non-diabetic rats ($p = 0.0008$ and $p < 0.0001$ respectively); the systolic blood pressure were similar in all studied groups. An increase of inducible nitric oxide synthase (iNOS) measured by western blot was observed in diabetic placebo (DM-placebo) ($p < 0.05$) compared with non-diabetic placebo (non-DM placebo) group. The treatment with polyphenol enriched cocoa prevented this upregulation ($p = 0.02$) in diabetic group. The retinal function, evaluated by ERG, showed a decrease in *b*-wave amplitude (post-photoreceptor response) in DM-placebo group compared with non-DM placebo. The cocoa treatment in diabetic rats protected this abnormality ($p = 0.01$). In ARPE-19 cells there was a significant increasing in ROS in cells exposed to high glucose compared to normal glucose ($p = 0.01$) and the presence of the cocoa inhibited about 30% of this ROS increase. The expression of claudin-1, a tight junction protein, was decreased in cells exposed to high glucose and it was prevented in presence of cocoa ($p < 0.05$).

Conclusion: In ARPE-19 cells, the polyphenol enriched cocoa treatment prevented the increase in ROS production and the decrease of claudin-1, an indicative of maintenance of outer BRB integrity. In diabetic rats, the treatment preserved the retinal function. Further studies are being conducted in order to better clarify the possible mechanisms involved in the beneficial effects of cocoa in diabetic milieu.

Human versus an automated grading system (Retmarker) in diabetic retinopathy screening

V. Maduro¹, V. Genro¹, J. Raposo¹, J. Feijo², C.M. Oliveira²;
¹Ophthalmology, APDP, Lisbon, ²Critical Health, Coimbra, Portugal.

Background and aims: Evaluate the benefits of using automated grading system (Retmarker technology) in screening diabetic retinopathy and compare this system with the golden standard (human grading).

Materials and methods: Anonymous retinal images (2 per eye) from 1092 patients screened in 2009 and 2010 were obtained using a non-mydiatic 45-degree fixed Cannon-45NM camera on a Diabetic Retinopathy screening program run by APDP. Images were taken and graded by 3 experienced ophthalmologist. Additionally, images were evaluated by an automated grading system - Retmarker - and classified as "Disease", "No disease". Retmarker technology performs a 2-step analysis based on the detection of Microaneurysms and Lesion Activity (progression) within the macular region. Results of the automated analysis were compared with those obtained by manual grading.

Results: The Retmarker software classified, from the 1092 patients, 539 (49.4%) as having "Disease" and 553 (50.6%) as having "No disease", thus requiring manual grading. Retmarker achieves a sensitivity of 81.4% and a specificity of 52% with a negative predictive value of 98.6% and a positive predictive value of 6.5% when compared human grading based on patient referral criteria. A total of 8 cases marked by the human grading as having signs of Diabetic Retinopathy were not detected by the automated system, out of the 1092 patients (0.73%).

Conclusion: Automated grading of diabetic Retinopathy may safely reduce the burden of grading patients with and without disease in Diabetic Retinopathy screening programs. The novel two-step automated analysis system using Retmarker has the capability to reduce the human workload of grading by approximately 50.6%, while achieving a high sensitivity of 81.4%. Applying an automated program, such as the described one, an important reduction in the number of cases the expert needs to address is achieved, and thus there is an associated cost saving. Most importantly, an automated system, although not providing full detection, provides consistency by removing subjectivity.

1117

Validation of a predictive model for diabetic retinopathy progression in type-2 diabetic patients with mild NPDR

S. Nunes¹, R. Bernardes^{2,3}, T. Santos², I. Pires⁴, C. Lobo^{4,3}, J. Cunha-Vaz⁵;

¹Coimbra Coordinating Centre for Clinical Research, Association for Innovation and Biomedical Research on Light and Image (AIBILI), ²Centre of New Technologies for Medicine, Association for Innovation and Biomedical Research on Light and Image (AIBILI), ³Institute of Biomedical Research on Light and Image (IBILI), Faculty of Medicine, University of Coimbra, ⁴Centre for Clinical Trials, Association for Innovation and Biomedical Research on Light and Image (AIBILI), ⁵Association for Innovation and Biomedical Research on Light and Image (AIBILI), Coimbra, Portugal.

Background and aims: To validate a predictive model for diabetic retinopathy progression in type-2 diabetic patients with mild NPDR using non-invasive examinations.

Materials and methods: Four-hundred and twelve (412) type-2 diabetic patients with mild NPDR were included in this 2-years observational and prospective study. Three hundred and seventy-four (374) patients completed the first 6-month of follow-up and underwent: color fundus photography, retinal thickness (RT) measurements and blood tests. Microaneurysm formation rate (MAFR) was computed from color fundus photographs using a new automatic method for MA earmarking (RetmarkerDR, Critical Health SA.). Increased RT maps (Stratus OCT, Zeiss Meditec Inc.) were computed using proprietary software.

Results: Three hundred and seventy-one (371) patients were included in the analysis (1 patient was lost of follow-up and 3 patients were treated with laser photocoagulation before the 6-month visit). Patients were distributed according to RT values and MAFR into 3 distinct DR phenotypes: Phenotype 1 (low MAFR and normal RT); Phenotype 2 (low MAFR and increased RT) and; Phenotype 3 (high MAFR). One hundred and fifty (150, 40.4%) patients were assigned to Phenotype 1, 116 (31.3%) to Phenotype 2 and; 105 (28.3%) to Phenotype 3.

notype 3. Clinically significant macular edema occurred during the follow-up period only in eyes from phenotype 2 (9 eyes, 7.8%) and phenotype 3 (7 eyes, 6.7%).

Conclusion: Our preliminary data confirms the existence of 3 different phenotypes of DR progression, as previously proposed, and simultaneously shows a similar distribution although using a different population.

Clinical Trial Registration Number: NCT00763802

Altered fibrin clot properties are associated with retinopathy in type 2 diabetes mellitus

M. Waluś-Miarka¹, P. Wołkow², K. Cyganek¹, B. Sieradzka¹, A. Undas³, M.T. Malecki¹

¹Department of Metabolic Diseases, Collegium Medicum, Jagiellonian University, ²Department of Pharmacology, Collegium Medicum, Jagiellonian University, ³Institute of Cardiology, Collegium Medicum, Jagiellonian University, Kraków, Poland.

Background and aims: Development and progression of diabetic retinopathy (DR) in type 2 diabetes mellitus (T2DM) have been associated with poor glycemic control, long disease duration and some other clinical features. However, the pathogenesis of this complication is still poorly understood. Formation of dense fibrin clots resistant to lysis has been described in patients with diabetes. It is unclear whether abnormal fibrin clot properties may predispose to vascular complications, including DR, in T2DM. We tested the hypothesis that altered clot structure and function are associated with DR in T2DM patients.

Materials and methods: We included 182 consecutive European Caucasian patients with T2DM lasting for at least 5 years (mean age at examination 56.3 ± 6.52 years). There were 111 (61%) T2DM patients without diabetic retinopathy (NDR) and 71 T2DM with DR (mean age 55.7 ± 6.2 and 57.1 ± 7 years, respectively, $p = \text{NS}$). The average duration of T2DM was 7.8 ± 5.6 in the NDR and 13.4 ± 6.8 years in the DR group, respectively ($p < 10^{-7}$). We assessed plasma fibrin clot permeation using a pressure-driven system, expressed as a permeation coefficient (Ks), indicating the pore size, and the time required for a 50% decrease in clot turbidity ($t_{50\%}$) as a marker of susceptibility to fibrinolysis. All patients underwent ophthalmological examination including fundus photography. Potentially important clinical and biochemical covariables were also measured. Determinants of DR were identified using stepwise multivariable logistic regression analysis.

Results: Patients with DR had lower clot permeability than those free of this complication (Ks 7.53 ± 1.24 vs 6.15 ± 1.18 [10^{-9}cm^2], respectively; $p < .0001$). Fibrin clot degradation by tPA was slower in DR patients ($t_{50\%}$ 10.12 ± 1.24 vs 9.12 ± 1.4 min, respectively; $p < .0001$). Logistic analysis revealed associations between DR and Ks, $t_{50\%}$, fasting glucose, HbA1c, insulin and C-peptide ($p < .05$). After adjustment for these variables, as well as for age and gender, associations between Ks and $t_{50\%}$ with DR proved to be significant.

Conclusion: Our study is the first to show that formation of compact fibrin clots and impairment of clot lysis characterize T2DM patients with retinopathy. These results might be relevant for new preventive strategies of DR in T2DM.

1119

Glomerular filtration rate deterioration as the high intraocular value of the vascular endothelial growth factor is seemed to be the marker of diabetic retinopathy progression after cataract surgery

A.G. Kuzmin¹, D.V. Lipatov¹, T.A. Chistyakov¹, O.M. Smirnova², M.I. Arbuzova², A.V. Ilyin², M.V. Shestakova²

¹Diabetic retinopathy and ophthalmic surgery, Research Centre of Endocrinology, ²Research Centre of Endocrinology, Moscow, Russian Federation.

Background and aims: Cataract surgery in diabetics is associated with the higher intraoperative complications incidence and poor visual outcome than in non-diabetics because of the diabetic retinopathy (DR) progression. Detection of the DR progression markers and preventing treatment performing are highly important. The aim of the study was to estimate the influence of the vascular endothelial growth factor (VEGF) value in the aqueous humor (AH) and glomerular filtration rate (GFR) deterioration on the DR progres-

sion after cataract surgery. The study was cross-sectional study with following prospective observation for 12 months in humans.

Materials and methods: In the study were included 120 patients with diabetes mellitus (DM) underwent the cataract phacoemulsification with intraocular posterior lens implantation. All patients were examined by ophthalmologist and to analyze glycemia, glycated hemoglobin, GFR before operation. At the operation beginning the samples of the AH were obtain to excess the VEGF value (by the enzyme-linked immunosorbent assay). There were the estimation of visual acuity (VA) using a Golovin-Sivtsev table from a 5-m distance and color fundus photography at 5th day and at 12 month after operation and the detection of neovascular complications (such as neovascular glaucoma (NG)). There was relative risk measurement, significance was proved using chi-square statistic.

Results: There was noted that than more severe DR was than VEGF level in the AH was higher. The patients with severe nonproliferative DR and proliferative DR had poor VA after operation, than patients with mild NPDR, although before operation they didn't differ by VA. Patients with high VEGF level in the AH had 9,62-fold risk ($p = 0,0004$) of DR progression (NG was developed in 25% of cases) and they had lower VA at the 12 month after operation than patients with lower VEGF level in the AH. The incidence of the NG in patients with GFR above $60 \text{ ml/min/1,73m}^2$ was 3%, in patients with GFR below $60 \text{ ml/min/1,73m}^2$ was 17%. There was VA at the 12 month similar in these groups. Reduced GFR (below $60 \text{ ml/min/1,73m}^2$) was associated with 5,9-fold risk of NG progression after cataract surgery ($p = 0,009$). There wasn't noted the correlation between GFR and VEGF value in the AH. Other parameters (high glycated hemoglobin, glaucoma presents, blood pressure, laser treatment and diabetic nephropathy) didn't achieve the statistic significant value.

Factorial analysis of the risk factors NG development after cataract surgery

Parameter	Relative risk	Odds ratio	chi-square test, p-value
VEGF value in the AH above 137,4 pg/ml	9,62	12,3	0,0004
GFR below $60 \text{ ml/min/1,73m}^2$	5,9	7,0	0,009
Glycated hemoglobin > 7,5%	3,5	4,8	0,12
Open-angle glaucoma incidence	3,09	3,6	0,09
Performed laser photocoagulation of the retina before operation	1,65	1,8	0,58
High blood pressure (>160/80 mm Hg)	1,82	1,8	0,58
Microalbuminuria/proteinuria incidence	2,8	3,1	0,12

Conclusion: Increased VEGF in the AH and reduced GFR significantly enhanced the risk of NG development after cataract phacoemulsification in diabetics.

The prevalence of clinically significant macular edema in patients with type 2 diabetes: Istanbul diabetic retinopathy study - IDRS report 2

S. Karadeniz¹, T. Yilmaz²

¹Ophthalmology, Group Florence Nightingale Sisli Hospital, Istanbul, Turkey, ²Endocrinology and Metabolism, Istanbul University, Medical Faculty, Turkey.

Background and aims: To determine the prevalence of clinically significant macular edema (CSME) in people with type 2 diabetes (T2DM) who have applied to the Diabetes outpatient Clinic between the years 1998 and 2010.

Materials and methods: This study includes 5 818 patients with T2DM (F/M 2189/3629, mean duration of DM 8.9 ± 7.8 years, mean chronological age 57.3 ± 11.2 years). The patients were seen by the same ophthalmologist at their visit to the Diabetes Outpatient Clinic or were referred as a routine diabetes follow-up for fundus examination between the years 1998 and 2010. The findings at their last visit for ophthalmological examination were considered. All patients underwent a comprehensive ophthalmologic evaluation, including funduscopy using a 78 D aspheric lens with a slit lamp and an indirect ophthalmoscopic examination. In addition fundus fluorescein angiography and OCT were performed if necessary. The CSME was defined according to the Early Treatment Diabetic Retinopathy Study classification protocol or if there was a prior history of macular edema with evidence of photocoagulation treatment and fundus fluorescein angiography and/or OCT consistent with it.

Results: Diabetic retinopathy was present in 2195 patients (37.7%). Clinically significant macular edema was diagnosed in 405 patients (7.0%). The preva-

lence of CSME rose from 2.2% in patients with duration of diabetes less than 6 years to 16.0% in patients with duration of diabetes more than 15 years.

Conclusion: High prevalence of diabetic CSME in people with T2DM and especially in the group with duration of T2DM more than 15 years is noticeable. These findings support the need both for identification and modification of risk factors for the development of CSME in order to prevent it and also timely diagnosis and effective treatment for the patients who suffer from it.

1121

Psychometric validation of the NEI-VFQ 25 in patients with diabetic macular edema

J.V. Loftus¹, A. Lloyd², M. Turner³, G. Lai³, S. Doyle², A. Pleil⁴;

¹Pfizer Ltd, Tadworth, ²Oxford Outcomes, UK, ³ICON Plc, San Francisco,

⁴Pfizer Inc, La Jolla, USA.

Background and aims: Diabetic macular edema (DME) is a common cause of impaired vision and blindness amongst diabetic patients. If not detected and treated early, the resulting vision loss can lead to considerable health costs and decreased health-related quality of life (HRQoL). The aim of this study was to provide evidence of the psychometric properties (i.e. reliability, validity, responsiveness, clinically meaningful change) of the National Eye Institute - Visual Functioning Questionnaire (NEI-VFQ 25) for use in a cohort of DME patients who participated in a clinical efficacy and safety trial of pegaptanib sodium (Macugen).

Materials and methods: A phase 2/3 randomised, double masked trial evaluated pegaptanib injection versus sham injection in patients with DME. The modified intent-to-treat analysis comprised 235 patients. QoL was measured using the NEI-VFQ 25 and the EQ-5D health index. The NEI-VFQ 25 was administered by a trained interviewer by telephone in the week prior to baseline and 54 weeks of treatment along with the EQ-5D health index. The NEI-VFQ 25 is a vision-specific measure of QoL composed of 8 multi-item scales, 4 single-item scales, and 1 composite score ranging in value from 0 (poor) to 100 (high HRQoL). Distance visual acuity (DVA), measured according to the Early Treatment Diabetic Retinopathy Study (ETDRS), was assessed at all time points.

Results: The overall operating characteristics of the NEI-VFQ 25 are supported. Exploratory factor analysis suggest that an 11 rather than 12 factor solution may be appropriate; however, variable clustering methods show that none of the 8 established multi-item scales met the criterion for further splitting. Internal consistency reliability was demonstrated for 7 out of 8 multi-item scales with Cronbach's alpha ranging from 0.58 (Distance Activities) to 0.85 (Vision Specific: Dependency). With the exception of ocular pain, the VFQ domains generally showed a low to moderate correlation with EQ-5D visual analogue scale (range 0.16–0.43) and visual acuity score (range 0.10–0.41). Construct validity was upheld with higher VFQ scores for patients who see more letters according to the ETDRS. All scales were shown to be responsive (except for Social Functioning) with Guyatt's statistic ranging from 0.10 to 0.56 at 54 weeks.

Conclusion: The NEI-VFQ 25 is a valid and reliable patient reported outcome instrument for use in DME. The existing 12-domain factor structure appears to be adequate though researchers may want to consider additional analyses with different datasets of DME patients to confirm this.

Pooled safety analysis in patients with visual impairment due to diabetic macular edema treated with 0.5 mg ranibizumab in RESOLVE and RESTORE trials

F. Bandello¹, G.E. Lang², R.O. Schlingemann³, D. Leclair⁴, A. Weichselberger⁵;

¹Department of Ophthalmology, University Vita-Salute Scientific Institute,

San Raffaele, Milano, Italy, ²Department of Ophthalmology, University

Eye Hospital, Ulm, Germany, ³Department of Ophthalmology, Academic

Medical Center, Amsterdam, Netherlands, ⁴Novartis Pharmaceuticals

Corporation, East Hanover, USA, ⁵Novartis Pharma AG, Basel, Switzerland.

Background and aims: The pivotal trials RESOLVE (n=151, phase II) and RESTORE (n=345, phase III) have demonstrated the efficacy and tolerability of repeated intra-ocular ranibizumab injections in patients with visual impairment due to diabetic macular edema (DME), a complication occurring in 1–3% of diabetic patients. The aim of the present analysis is to evaluate the

overall relative risk (RR) of targeted adverse events (AEs) in patients treated with ranibizumab in these two controlled trials.

Materials and methods: In total 217 patients treated with 0.3–1.0 mg ranibizumab and 159 control patients treated with sham (RESOLVE) or laser photocoagulation (RESTORE) were assessed. The 12-month RR of the following targeted ocular and systemic AEs was evaluated: hypersensitivity reactions, retinal pigment epithelial tear, endophthalmitis, retinal detachment, retinal tear, cataract, intraocular inflammation, intraocular pressure (IOP) increase, vitreous hemorrhage, hypertension, non-ocular hemorrhage, proteinuria, myocardial infarction (MI), non-MI arterial thromboembolic events, venous thromboembolic events, deterioration of retinal blood flow (including central retinal artery occlusion).

Results: Relative to controls, ranibizumab treatment was associated with an increased RR [95% confidence interval] at 12 months of the following AEs: IOP increase (8.79 [2.11, 36.67]), vitreous hemorrhage (2.20 [0.45, 10.75]), non-ocular hemorrhage (1.47 [0.27, 7.9]), and arterial thromboembolic events (except MI) (1.22 [0.30, 5.04]). Endophthalmitis and proteinuria were observed in 1.4% and 0.5% patients treated with ranibizumab, respectively. There was no overall increased RR for the other targeted AEs.

Conclusion: The results of this analysis are consistent with the established safety profile of 0.5 mg ranibizumab, licensed for the treatment of visual impairment due to DME in Europe in 2011, and did not reveal any new ocular or systemic safety risks.

Addition of liraglutide improves retinal endothelial function and vascular risk profile in type 2 diabetic patients well controlled by metformin monotherapy

M. Mitry¹, T. Forst¹, G. Michelson², F. Ratter³, M.M. Weber⁴, S. Anders⁵,

B. Wilhelm³, A. Pfützner²;

¹Medical, Institute for Clinical Research and Development, Mainz,

²Interdisciplinary Centre for Ophthalmic Medicine and Imaging, Friedrich

Alexander University, Erlangen-Nuernberg, ³Medical, Novo Nordisk, Mainz,

⁴Endocrinology, Johannes Gutenberg University, Mainz, ⁵Clinical Research, Institute for Clinical Research and Development, Mainz, Germany.

Background and aims: GLP-1 receptor agonists have been introduced in the treatment of type 2 diabetes mellitus (T2DM). Beside their metabolic effects, GLP-1 agonists were shown to address vascular biology and to affect endothelial function.

Materials and methods: This two arm, parallel study, included 40 well controlled patients with T2DM (20 male, age: 56.5±6.1 years; duration of diabetes: 4.3±3.1 years; HbA1c: 6.3±0.4 %; mean±SD). Main inclusion criteria were: pretreatment with metformin on a stable dosage, HbA1c < 7.0%, age 30 – 65 years. Patients were randomized to receive additional liraglutide in a stepwise escalating dosage from 0.6 mg to 1.8 mg or to remain on metformin monotherapy. After 6 weeks (1.2mg) and after 12 weeks (1.8 mg) retinal capillary blood flow was assessed using a retinal laser doppler scanner at 670 nm (Heidelberg Retina Flowmeter, Heidelberg Engineering) at baseline and 20 seconds after flicker light stimulation. In addition, venous blood was taken for the measurement of several laboratory markers characterizing vascular and endothelial function.

Results: As shown in the table, blood glucose control and body weight declined in patients receiving liraglutide in addition to their previous metformin treatment (p<0.01), while glucose control and body weight remained unchanged in those patients remaining on metformin monotherapy. The retinal microvascular hyperaemic response to flicker light stimulation tended to increase during treatment with liraglutide within the first 6 weeks (p=0.06). Even this effect of liraglutide was somewhat attenuated after 12 weeks of treatment, it still remained detectable (p=0.07). In patients on metformin monotherapy a slight, albeit non significant, deterioration in the retinal hyperaemic response could be observed. During treatment with liraglutide, a continuous decline in ADMA, E-Selectin, PAI-1, and intact proinsulin levels was obtained (p<0.05 respectively). No such effects could be found during sustained treatment with metformin.

Conclusion: This pilot study suggests a beneficial effect for the treatment with the GLP-1 receptor agonist liraglutide on retinal endothelial function, which runs in parallel with an improvement in laboratory markers for endothelial and vascular function.

Table 1. Study Parameters at baseline and after 6 and 12 weeks of study treatment (mean±SD)

	Met	Met	Met	Lira+Met	Lira+Met	Lira+Met
	Baseline	6 weeks	12 weeks	Baseline	6 weeks	12 weeks

Insulin regulates tyrosine hydroxylase expression in neuronal pc12 cells

F. Fiory^{1,2}, P. Mirra^{1,2}, C. Nigro^{1,2}, M. Lucariello^{1,2}, P. Ungaro^{1,2}, P. Formisano^{1,2}, C. Miele^{1,2}, F. Beguinot^{1,2};

¹University of Naples Federico II, ²Icos, CNR, Naples, Italy.

Background and aims: Impairment of insulin synthesis or action is associated with neurodegenerative disease and with a decline in cognitive function. Recent studies show that diabetes represents a risk factor for dementia. Streptozotocin-diabetic rats have lower catecholamines levels in the corpus striatum and immunoreactive tyrosine hydroxylase (TH), the rate limiting enzyme in catecholamines synthesis, is decreased in nigrostriatal neurons of the genetically diabetic BB Wistar rats. Moreover, insulin treatment raised TH mRNA levels in intact adrenals. Hif-1 alpha is the alpha subunit of a heterodimeric basic helix-loop-helix factor activated by ERK and PI3K in response to growth factor and hypoxia. It is known that Hif-1 alpha is able to bind TH promoter.

Materials and methods: TH protein and mRNA levels in PC12 cells were evaluated by Western blot and RT-PCR respectively. ChIP experiments were performed to evaluate Hif-1 alpha binding on TH promoter.

Results: We have evaluated insulin ability to regulate the TH levels in PC12 cells. Insulin induces IR and IRSs tyrosine phosphorylation and PKB and ERK activation in PC12 cells. Treatment of PC12 cells with 100nM insulin for 2 hours leads to a 7-fold increase in the mRNA levels of TH. TH protein levels are also increased upon 2, 4 and 6 hours of insulin treatment. Pretreatment of PC12 cells either with 50 μM LY294002, a PI3K inhibitor, for 30' or with 50 μM PD98059, a MAPK inhibitor, for 1h completely abolished insulin induced increase of TH mRNA and protein levels. Moreover, insulin stimulation increases the binding of Hif-1 alpha to TH promoter. The pretreatment of PC12 cells for 16h with 100nM chetomin, a Hif-1 alpha inhibitor, almost completely abolished insulin positive effect on TH mRNA, confirming the role of Hif-1 alpha in insulin regulation of TH expression.

Conclusion: These results suggest that insulin effect on TH mRNA is mediated by Hif-1 alpha activation through an ERK/PI3K dependent mechanism. Thus, improvement of insulin signal transduction in brain could preserve neurotransmitters content in diabetic condition.

Impaired release of serotonin at the spinal cord of STZ-diabetic rats

C. Morgado¹, P. Pereira-Terra¹, F. Neto¹, T. Mixcoatl-Zecuatl², N.A. Calcutt², I. Tavares¹;

¹Institute of Histology and Embryology - FMUP and IBMC; University of Porto, Portugal, ²Department of Pathology; University of California, San Diego, USA.

Background and aims: Spontaneous pain is an important complaint associated with diabetic neuropathy. It is caused by disarrangements at the somatosensory system, which seem to involve both peripheral and central mechanisms. As to the central mechanisms, we have previously shown that long-term diabetes is associated with hyperactivity of the spinal nociceptive neurons and impairments in the serotonergic neuronal population of the rostroventromedial medulla (RVM). The RVM plays a key role in pain control by sending serotonergic neuronal projections to the spinal dorsal horn. At spinal level serotonin acts by inhibiting or enhancing spinal neurotransmission, according to the receptor it binds. Considering the impairments detected at the spinal dorsal horn and RVM during diabetic neuropathy it is likely that spinal serotonergic neurotransmission is disrupted in this pain condition. The aim of the present study was to evaluate the levels of serotonin in spinal homogenates and in cerebrospinal fluid (CSF) collected from the lumbar spinal cord of streptozotocin (STZ)-diabetic rats, along with the evaluation of monoamine oxidase A (MAO A) activity, the main enzyme involved in serotonin degradation.

Materials and methods: Diabetes was induced by intraperitoneal injection of STZ in male Wistar rats. Control received equal volumes of vehicle solution. At 10 weeks post-injection, an intrathecal catheter was placed in the subarachnoid space with the tip at the level of L4-L5 spinal segments and approximately 100μl of CSF was collected. Two other groups of STZ and control rats

were sacrificed and L4–L5 spinal segments were removed and homogenised. Serotonin contents were quantified by ELISA in the spinal homogenates and CSFs and MAO A activity was evaluated in the spinal homogenates. SPSS was used for statistical analysis and data were compared by independent sample t test. Statistical significance was settled at $p < 0.05$.

Results: STZ rats presented increased levels of serotonin in spinal homogenates (STZ: 0.4 ± 0.04 ng/mg tissue; Control: 0.3 ± 0.03 ng/mg tissue), but significant decreased levels in CSF (STZ: 0.3 ± 0.11 ng/ μ g protein; Control: 7.4 ± 1.07 ng/ μ g protein). The activity of MAO A was significantly lower at the spinal cord of STZ rats when compared with the age-matched non-diabetic control animals (STZ: 1.9 ± 1.14 nmol/mg protein/h; Control: 5.8 ± 1.35 nmol/mg protein/h).

Conclusion: These results point to impairments in the mechanisms of serotonin release during diabetes. The increased levels of serotonin at the spinal cord homogenates of STZ rats could represent increased accumulation of serotonin at axonal terminals from the descending RVM neuronal projections, probably caused by the decline in the release and degradation of the neurotransmitter, as suggested by the decreased levels of serotonin at the CSFs and the reduction in MAO A activity. It is likely that the impaired release of serotonin at the spinal cord will attenuate the serotonergic inhibitory action upon spinal nociceptive transmission, which may account to the spontaneous neuronal hyperactivity at the spinal cord and exacerbated pain responses detected in STZ-diabetic rats.

Suppression of neuropathy development in spontaneously diabetic GK rats by treatment with DPP-IV inhibitor, vildagliptin

H. Mizukami, W. Inaba, K. Takahashi, S. Yagihashi;

Pathology and Molecular Medicine, Hirosaki University Graduate School of Medicine, Japan.

Background and aims: Incretin is now widely used as a new type of treatment for diabetes. The incretin effects on chronic complications of diabetes attract an attention because the prevention and inhibition of the development of complications are the final purpose of diabetes management. In this study, we explored whether long-term treatment with DPP-IV inhibitor is beneficial for the neuropathy in spontaneously diabetic GK rats, non-obese type 2 diabetic model, and if it is to clarify the mechanism.

Materials and methods: Male GK rats 4 weeks of age were treated with DPP-IV inhibitor (DI: vildagliptin) at a dose of 15 mg/kg/day orally twice a day for 18 weeks. During the observation period, body weight, blood glucose, nerve conduction velocities (NCVs) were monitored regularly. Normal Wistar rats were treated in a similar manner and untreated animals served as controls. At end, all the animals were killed, and dorsal root ganglia (DRG) and sciatic nerves were extirpated for structural observations. To explore the mechanism of how DI influences on the neuropathic changes, molecular analysis on DRG and sciatic nerve tissues was conducted.

Results: Both motor and sensory NCVs were significantly delayed in GK rats. DI treatment improved the delay to 80% and 75% of normal levels, respectively, while DI treatment suppressed postprandial hyperglycemia by 26%. Average neuronal size in DRG was reduced in GK rats compared to control animals and normalized by DI-treatment. Reduced neuropeptide expression of CGRP was also improved in DI-treated rats. RT-PCR analysis disclosed the presence of both GLP-1R and GIP-R in DRG but not in the sciatic nerve. Western blots demonstrated marked reduction of Akt and phospho-Akt expressions in DRG of GK rats which was recovered to near 70% of normal levels. The alterations of cellular signaling were associated with significant recovery of suppressed mRNA expression of arginase I, a CREB-associated axon-growth enhancer, in DI-treated GK rats.

Conclusion: Neuropathic changes in GK rats were ameliorated by DI (vildagliptin) treatment which may have directly exerted Akt-phospho-Akt pathway via activated GLP-1, resulting in promoting arginase I which plays a central role in the maintenance of peripheral axons. In addition, improvement of glucose tolerance by DI-treatment may also have contributed to the recovery of peripheral nerve changes.

1127

Prevention and reversal of diabetic neuropathy by treatment with ghrelin M. Nakazato;

Internal Medicine, University of Miyazaki, Japan.

Ghrelin, an acylated peptide produced in the stomach, increases food intake and growth hormone (GH) secretion, suppresses inflammation and oxidative stress, and promotes cell survival and proliferation. Polyneuropathy is the most common complication of diabetes mellitus, but none of agents approved for clinical use. Ghrelin's diverse functions raise the possibility of its clinical application; clinical trials with ghrelin for anorexia nervosa, diabetic gastroparesis, and cachexia have commenced. We investigated the pharmacological potential of ghrelin in the treatment of diabetic polyneuropathy in rodents and humans. Experimental diabetic polyneuropathy was induced by streptozotocin injection in C57BL/6N mice, ghrelin receptor knockout mice (GHS-R^{-/-}), and GH deficient rats. Ghrelin or desacyl-ghrelin, which lacks the acyl modification, was administered daily for 4 weeks immediately after disease onset or 4 weeks after streptozotocin injection. Ghrelin administration did not alter food intake, body weight gain, or blood glucose levels in C57BL/6N mice when compared with mice administered saline or desacyl-ghrelin. Ghrelin administration prevented and alleviated motor and sensory polyneuropathy in C57BL/6N mice in both preventive and therapeutic studies. Ghrelin reduced the plasma concentrations of oxidative stress markers and ameliorated reductions in fiber number and fiber density of sciatic nerves. In all experiments, desacyl-ghrelin failed to show any effect. Ghrelin prevented the reduction of nerve conduction velocities in GH deficient rats, but not in GHS-R^{-/-} mice. We have completed preliminary clinical application of ghrelin to type 2 diabetic patients without insulin therapy. Ghrelin at 1 μ g/kg BW was administered iv after breakfast for 2 weeks. Ghrelin did not change food intake or body weight. Ghrelin increased plasma GH level 60 ng/ml in healthy subjects at 15 min after iv injection, while ghrelin increased it to 16 ng/ml in diabetics. Ghrelin improved motor conduction velocity of the tibial nerve, sensory conduction velocity of the sural nerve, and polyneuropathy-related symptoms in all the patients. Thus, ghrelin's effects represent a novel therapeutic paradigm for the treatment of this otherwise intractable disorder. Ghrelin also prevented and alleviated muscle atrophy in a mouse model of disused muscle atrophy. Ghrelin is highly likely to be used as a novel peptide drug for diabetes mellitus and cachexia.

Effects of the 11betaHSD1 inhibitor SAR184841 on peripheral neuropathy in Zucker Diabetic Fatty rats

L. Noah¹, A. Castro², B. De Miguel², R. Lopez², A. Burriel², D. Simard¹, M.-P. Pruniaux¹;

¹sanofi aventis, Chilly-Mazarin, France, ²sanofi aventis, Alcorcon, Spain.

Background and aims: Selective 11betaHSD1 inhibitors may provide potential therapeutic treatment for patients suffering from T2D or T2D-associated complications. Such compounds have not been reported to improve microvascular complications, such as peripheral neuropathy, while specific treatments addressing these diseases still represent an unmet medical need. The aim of the study was to evaluate the effect of SAR184841, a selective 11betaHSD1 inhibitor (human IC₅₀=4nM), on glucose homeostasis, blood lipid profile, and peripheral neuropathy in a rodent model of Type 2 Diabetes.

Materials and methods: Male Zucker Diabetic Fatty (ZDF-fa/fa) rats and their lean (fa/?) controls, 11 weeks-old at the beginning of experiments, were used in the study. Diabetic (fa/fa) animals were treated with SAR184841 (30 mg/kg/day, n=10), the antihypertensive irbesartan (~30 mg/kg/day, n=10), or the oral antidiabetic rosiglitazone (~5 mg/kg/day, n=10), in chow, and compared with a vehicle-control group (n=10). After a 4-week treatment, blood and plasma metabolic parameters were measured, and peripheral neuropathy was assessed by the in vivo measurement of motor nerve conduction velocity (MNCV) from the sciatic nerve.

Results: Rosiglitazone was the only treatment to improve blood glucose homeostasis over the 4 week-period, as illustrated by %HbA1c values (8.2 ± 0.8 for the rosiglitazone group vs 12.7 ± 1.3 for vehicle, $p < 0.01$), and a significant improvement of glucose tolerance measured after 3 weeks (AUC 0-120min: 33359 ± 4765 mg/dL*min for the rosiglitazone group vs 48180 ± 1845 mg/dL*min for vehicle, $p < 0.05$). None of the compounds significantly modified plasma insulin levels. While irbesartan (230.5 ± 26.2 mg/dL, -28% vs vehicle,

$p < 0.01$) and rosiglitazone (100.6 ± 4.2 mg/dL, -69% vs vehicle, $p < 0.01$) significantly decreased plasma triglycerides versus the control group (319.6 ± 28.5 mg/dL) at the end of the experiment, SAR184841 only showed a tendency to decrease this parameter (251.3 ± 20.2 mg/dL, -21% vs vehicle, $p = 0.05$). However, SAR184841 significantly decreased cholesterol levels after 4 weeks (164.2 ± 4.7 mg/dL for SAR184841 group vs 187.3 ± 8.2 mg/dL for vehicle, $p < 0.01$), whereas rosiglitazone and irbesartan had no effect. Interestingly, the MNCV, which was impaired in the vehicle-ZDF rats (31.8 ± 1.4 m/s vs 45.0 ± 1.3 m/s in lean animals), was significantly improved by SAR184841 (39.5 ± 2.0 m/s, $p < 0.01$ vs vehicle-ZDF), and by rosiglitazone (37.2 ± 1.2 m/s, $p < 0.05$ vs vehicle-ZDF). Irbesartan had no effect on this parameter (34.2 ± 0.7 m/s).

Conclusion: Taken together, these results show that the 11 β HSD1 inhibitor SAR184841 improved peripheral neuropathy in diabetic animals and that this effect can be achieved independently of a major effect on blood glucose control. Complementary histological studies are currently running to evaluate the structural alterations of intra-epidermal nerve fibres.

1129

Thermal nociceptive threshold in diabetic db/db mice: the use of loop-diuretics as analgesics

M. Di Fulvio, S. Alshahrani, K.M. Elased;
Pharmacology & Toxicology, Wright State University, Dayton, USA.

Background and aims: Almost one third of all diabetic patients suffer from painful diabetic neuropathy (PDN). PDN is characterized by hyperalgesia i.e., increased sensitivity to noxious stimulus. The primary target of PDN is the primary sensory neuron (PSN). GABA-mediated depolarization of PSNs is a fundamental event in gating the flow of nociceptive information in the spinal cord. GABA released from interneurons mediate primary afferent depolarization (PAD) via Cl⁻ channels coupled to GABAA receptors. This is possible because PSNs maintain their [Cl⁻]_i above electrochemical equilibrium generating and outwardly directed transmembrane Cl⁻ gradient. The Na⁺K⁺2Cl⁻ co-transporter 1 (NKCC) plays a key role in the generation and maintenance of this gradient. Hence, NKCC modulates and control PSN excitability, in particular nociceptive processing, and participates in the generation and maintenance of hyperalgesic states. Genetic ablation of NKCC1 expression in mice causes impaired nocifensive (pain-avoiding) behavior. In the hot-plate test of nociception, adult NKCC1 knock-out mice show longer response latencies to noxious heat and increased behavioral thresholds after intra-dermal capsaicin injection. However, this conventional method for the study of thermal nociception in rodents applies constant supra-threshold heat stimuli (52–55°C) and measures the reflex latency of nocifensive reactions of the animal. The response latency to noxious stimuli determined by these methods vary considerably upon repeated measurements, which is a major disadvantage concerning reliability and reproducibility.

Materials and methods: By applying a slowly increasing thermal stimulus we have determined the thermal nociceptive threshold of diabetic db/db and WT mice and the results were compared to the ones obtained with mice lacking NKCC1.

Results: The thermal nociceptive threshold, that is the lowest temperature at which the animal shows nocifensive behavior, of db/db mice, WT or NKCC1 KO mice were: $47.1 \pm 0.3^\circ\text{C}$ ($n=20$), $48.0 \pm 0.1^\circ\text{C}$ ($n=64$) and $49.2 \pm 0.2^\circ\text{C}$ ($n=34$), respectively ($p < 0.001$). Injection of non-diuretic doses of bumetanide (or furosemide), both inhibitors of NKCC, to these mice resulted in a significant increase in their thermal nociceptive thresholds ($p < 0.01$): db/db $49.1 \pm 0.4^\circ\text{C}$ ($n=7$), WT $50.0 \pm 0.3^\circ\text{C}$ ($n=8$) and KO $49.8 \pm 0.2^\circ\text{C}$ ($n=8$).

Conclusion: These results suggest that diabetic db/db mice are hyperalgesic whereas mice lacking NKCC1 have higher than normal thermal nociceptive thresholds. Furthermore, these thresholds could be increased after treatment with NKCC inhibitors, confirming a partial, although not exclusive role of NKCC in the maintenance of the thermal nociceptive threshold in these mice.

Effects of urotensin receptor antagonist SB-657510 in diabetic erectile dysfunction *in vitro*

M. Olukman, D. Çoşkunsever, F.G. Çelenk, C. Can, S. Ülker;
Medical Pharmacology, Ege University School of Medicine, Izmir, Turkey.

Background and aims: The pathogenesis of erectile dysfunction (ED) in diabetes mellitus (DM) is complex in nature, multifactorial and not understood in details. The prevalence of questionnaire-diagnosed ED in primary care is 30–50%. Urotensin-II (U-II) has been identified as an endogenous ligand for the orphan G-protein coupled receptor 14, initially named as sensorial epithelium neuropeptide-like receptor. Elevated plasma levels of U-II and increased expressions of U-II per se and its receptor (UT) have been demonstrated in numerous diseased conditions including hypertension, atherosclerosis, heart failure, pulmonary hypertension, diabetes, renal failure, and the metabolic syndrome. U-II significantly relaxes human corpus cavernosum strips in endothelium- and NO-dependent manner. The peptide caused a significant increase in intracavernous pressure in anesthetized rats although the cumulative addition of U-II was not able to produce either relaxation or additional contraction in pre-contracted cavernosal strips from rats or mice. We aimed to determine the role of UT antagonist, SB-657510 in diabetic ED.

Materials and methods: Diabetes was induced by multiple intraperitoneal streptozotocin injections (55 mg/kg/day, five days) in male Swiss albino mice. Animals were killed 6 weeks after last streptozotocin dosage. Cumulative concentration-response curves for the phenylephrine and Rho-kinase inhibitor Y-27632 (after 80% maximal phenylephrine precontraction) were determined. Cumulative responses to acetylcholine were measured to determine endothelium-dependent relaxation. Transmural electrical field stimulation (EFS) was delivered using platinum wire electrodes (duration 30 seconds, 2 to 64 Hz, 10-ms pulses, 40 V). In the presence of atropine (1 μM) and guanethidine (3 μM), nitrenergic nerve-mediated relaxation in response to electrical stimulation was assessed against phenylephrine precontraction. This protocol is repeated in both control and diabetic corpus cavernosum after incubation with 3×10^{-7} M SB-657510 for 30 minutes.

Results: Both contractile responses to phenylephrine and relaxant responses to EFS, acetylcholine and Y-27632 were increased in diabetic cavernosal strips. *In vitro* incubation of the diabetic strips with SB-657510 significantly prevented the increase in phenylephrine contractility ($p < 0.01$), whereas it further enhanced the increased relaxant responses ($p < 0.05$). In the control strips, EFS-induced relaxation was significantly attenuated after incubation with SB-657510 ($p < 0.05$).

Conclusion: This is the first study suggesting that U-II has an active involvement in the pathogenesis of diabetic ED and antagonism of UT with SB-657510 restores diabetes-induced ED. In conclusion, it is considered that U-II may be a good target in the research and development of drugs to treat diabetic ED.

The effect of aminoguanidine on cultured human fibroblasts exposure to advanced glycation end products

A.I. Serban¹, C.M. Munteanu², V.G. Tica², M. Costache², A. Dinischiotu²;
¹Biochemistry and Molecular Biology, University of Agricultural Science and Veterinary Medicine, ²Biochemistry and Molecular Biology, University of Bucharest, Faculty of Biology, Bucharest, Romania.

Background and aims: In diabetes, the excessive accumulation of extracellular matrix proteins and skin aging are considered to be due to advanced glycation end products (AGEs) formation. The aim of this study was to elucidate the controversial effect of aminoguanidine (AG) on the expression of AGEs receptor (RAGE) and TGF- β in relation to type I and III collagen regulation at transcriptional and translational levels in cultured fibroblasts exposure to AGE-BSA.

Materials and methods: The 70% confluent CCD-1070Sk fibroblast cultures were treated for 12 and 24 hours with 50 $\mu\text{g}/\text{ml}$ AGE-BSA in the presence and absence of 10–100 μM AG. The mRNA expression of all target genes was analyzed by qPCR. Type I and III collagen and TGF- β from conditioned media and RAGE from cell membranes were investigated by Western immunoblot.

Results: The cell treatment by 50 $\mu\text{g}/\text{ml}$ AGE-BSA up-regulated the mRNA and protein expression of RAGE, TGF- β and both procollagens $\alpha 2$ (I) and $\alpha 1$ (III). Thus, the relative expression ratio (R) increased to: 4.1 ± 0.25 for RAGE, 3.07 ± 0.32 for TGF- β , 5.85 ± 0.14 for procollagen $\alpha 2$ (I) respectively

2.73+/-0.34-fold after 12 hours and to 2.67+/-0.19, 1.81+/-0.35, 2+/-0.33 and 1.18+/-0.19 at 24 hours of exposure. After 12 hours of AGE-BSA and AG co-treatment, the relative expression ratio (R) of RAGE and TGF- β increased to 6.6+/-0.15 and 5.16+/-0.16-fold at 10 μ M AG and with the rise of AG concentration, R decreased but at 100 μ M AG it remained of 4.5+/-0.19 and 3.86+/-0.17 levels. R for procollagen α 2 (I) and α 1(III) increased with the rise of AG level and at 100 μ M AG, R for procollagen α 1(III) equalized the R for α 2 (I), being increased to 8+/-0.12. After 24 hours, R for all target genes decreased with the increase of AG concentration, but only at 100 μ M AG, R had subunitary value for RAGE and TGF- β . The relative protein expression of RAGE at 12 hours increased with AG concentration but at 24 hours decreased with AG level, reaching a subunitary value. In culture media, TGF- β had a similar profile with RAGE but its relative expression after 24 hours did not reach subunitary value. Both collagen types accumulated in time, reaching at 12 hours the same relative protein expression. After 24 hours of treatment, only the relative protein expression of type III collagen had a decreasing tendency reaching at 100 μ M AG the value recorded in the presence of 50 μ g/ml AGE-BSA.

Conclusion: Our results provide further evidence for the hypothesis that TGF- β is regulated by RAGE-AGE interaction and plays a pivotal role in mediating collagen deposition in diabetes context, especially at skin level. The positive effects of AG can be observed after 24 hours when it decreased the mRNA and protein expression of RAGE. Probably after 24 hours it could reduce the extracellular matrix accumulation of both collagen types, restoring the ratio collagen I/collagen III in the collagen's I favour.

Diabetes impairs the expression of the CB₁ cannabinoid receptor, the novel homeostatic regulator of the skin

E. Leal, D. Espinoza, A. Köfalvi, E. Carvalho;

Center for Neurosciences and Cell Biology, Coimbra, Portugal.

Background and aims: The G protein-coupled metabotropic cannabinoid receptor type-1 (CB₁R) is a major regulator of metabolism, growth and inflammation, and is present in most tissues of the body. For the first time, we aimed to test the expression of CB₁R and other factors of inflammation and regeneration in the skin of diabetic and in CB₁R knockout mice (CB₁R KO).

Materials and methods: We quantified by q-RT-PCR markers of proliferation, inflammation, angiogenesis and oxidative stress, in the skin of wild-type (WT) control, WT streptozotocin (STZ)-induced diabetic mice and CB₁R KO mice.

Results: In the skin of the CB₁R KO mice, the expression of 1) the growth factors, epithelial growth factor (EGF), fibroblast growth factor (FGF), stromal derived growth factor (SDF-1) and its receptor, CXCR4, 2) the inflammatory markers, interleukin-6 (IL-6), keratinocyte-derived chemokine (KC), tumor necrosis factor-alpha (TNF-alpha), monocyte chemoattractant protein-1 (MCP-1) and metalloproteinase-9 (MMP9), as well as 3) the antioxidant defense enzymes, heme-oxygenase-1 (HO-1) and superoxide dismutase (SOD), were all decreased when comparing with WT mice. Furthermore, we found that CB₁R expression is decreased in the skin of diabetic mice, indicating the possible impairment of the expression of these CB₁R-dependent homeostatic markers.

Conclusion: Apparently, the absence of CB₁Rs impairs the expression of several markers involved in the control of inflammation and tissue regeneration. Thus, the observed decrease in CB₁R expression may be a major pathologic mechanism in diabetic skin complications.

PS 102 Neuropathy: small fibres and pain

1133

Intraepidermal nerve fibre density is associated with weight

K. Pourhamidi¹, L.B. Dahlin², E. Englund³, O. Rolandsson¹;

¹Department of Public Health and Clinical Medicine, Family Medicine, Umeå University, ²Department of Clinical Sciences Malmö, Hand Surgery, Skåne University Hospital, Lund University, Malmö, ³Department of Pathology, Clinical Sciences, Lund University, Sweden.

Background and aims: Intraepidermal nerve fibre density (IENFD) quantification is regarded to be a sensitive and specific measure of small nerve fibre dysfunction and IENFD loss is an early feature in glucose dysregulation. Our aims were to study IENFD in individuals with normal glucose tolerance (NGT), impaired glucose tolerance (IGT) and type 2 diabetes (T2D) and to study if IENFD was associated to metabolic traits, e.g. obesity and dyslipidemia, and to neurophysiologic assessments of nerve function.

Materials and methods: Participants were consecutively recruited from the population-based Västerbotten Intervention Program; NGT (n=22), IGT (n=14), T2D (n=24), at the age of 60±1 years. The individuals' height and weight were measured. Blood glucose and lipids were measured. Nerve conduction studies (NCS) were performed (sural and peroneal nerves) and the results were standardized to z-scores and compiled into a composite Z-score representing the nerve function in the leg. Neuropathy disability score (NDS) was used to evaluate neuropathic signs. In addition, thermal threshold tests (TTT) were performed to assess small nerve fibre function. Skin biopsies were performed using a 3-mm punch taken 10 cm proximal to the lateral malleolus. The intraepidermal nerve fibres were evaluated by routine immunohistochemistry and stained with anti-PGP9.5 (ubiquitin carboxyl-terminal hydrolase) antibodies. Light microscopy was used to identify nerve fibres in thin sections (5 μ m) according to a standardized protocol. The IENFD was given as the mean of counts in 3 sections per millimeter of epidermal length. The assessors were blinded to the identity of the samples.

Results: Patients with diabetes had lower IENFD (median 2.9 nerves mm⁻¹, IQR 1.2-4.8) than controls (median 4.4 nerves mm⁻¹, IQR 3.5-6.3; Mann-Whitney U test p=0.007). IGT individuals did not differ in IENFD (median 3.2 nerves mm⁻¹, IQR 1.4-5.5) compared to controls (p=0.12) or diabetic patients (p=0.53). IENFD was positively correlated to NCS (r=0.39, p=0.002), but not to TTT and NDS. Individuals in the 3rd tertile of composite Z-score (i.e. better nerve conduction) had higher IENFD (median 4.1 nerves mm⁻¹, IQR 2.7-5.8) than individuals in the 1st tertile (median 2.4 nerves mm⁻¹, IQR 0.7-3.9; p=0.009). Triglycerides and cholesterol were not associated with IENFD. However, a stepwise multiple linear regression analysis revealed that weight was independently associated to IENFD, after adjustment for age, sex, height, and diabetic status (β = -0.419, p<0.001).

Conclusion: We conclude that skin biopsies for IENFD quantification in thin sections is a simple useful method for assessing small nerve fibre neuropathy in individuals with diabetes. The association between weight and IENFD indicates that metabolic traits other than glucose dysmetabolism might play a role in the development small nerve fibre neuropathy.

Corneal nerve fibre damage defined using corneal confocal microscopy in relation to tear film proteomics

M. Tavakoli, I. Petropoulos, H. Fadavi, U. Alam, O. Asghar, G. Ponirakis, A.J.M. Boulton, R.A. Malik; University of Manchester, UK.

Aims: The novel technique of corneal confocal microscopy has previously identified early and significant corneal nerve damage in diabetic patients. However, the mechanistic basis of the damage has not been explored. We have therefore undertaken an analysis of differentially expressed proteins in type 1 diabetic patients with neuropathy compared to healthy controls.

Methods: 10 type 1 diabetic patients (age: 52 ± 5) with a long duration of diabetes (38 ± 4 yrs) and 5 control subjects (age: 33 ± 5 yrs) underwent assessment for neuropathy. Tear samples were collected using micro-capillary tubes and analysed by LC-MS label-free comparative peptide profiling. The data acquired was searched against a human protein database and reviewed in the OBS DECIDER database.

Results: Diabetic patients had a significant neuropathy (NDS- 8.5 ± 4.8 v 0.20 ± 0.20 , $P = 0.2$), VPT (27.9 ± 8.9 v 2.9 ± 0.4 , $P = 0.07$) and using the novel technique of corneal confocal microscopy a significant reduction in corneal nerve fibre density (18.3 ± 3.7 v 35.9 ± 2.8 , $P = 0.01$), branch density (32.8 ± 10.13 v 67.4 ± 14.4 , $P = 0.08$) and length (14.6 ± 2.1 v 25.4 ± 2.2 , $P = 0.009$). In the tear samples an initial set of 36 differentially expressed proteins were identified from 103 statistically significantly different peptides in diabetic patients with neuropathy compared to control subjects. The following proteins were particularly significantly increased: Ceruloplasmin (5.90 fold, $P = 0.02$); Cystatin-C (1.4 fold, $P = 0.03$); Galectin-3-binding-protein (5.10 fold, $P = 0.04$); Lysozyme C (8.50 fold, $P = 0.0001$); Nucleobindin-2 (7.67 fold, $P = 0.01$); SPARC-like protein 1 (4.19 fold, $P = 0.05$). The following proteins were significantly decreased: AntileukoproteinaseALP (5.09 fold, $P = 0.05$); Caskin-1 (3.89 fold, $P = 0.02$); Complement C3 (4.67 fold, $P = 0.07$); Haptoglobin (-10.82 fold, $P = 0.003$); prolactin-inducible protein (-1.39, $p = 0.005$); vonWillebrand factor A domain containing protein 3A (-7.02 fold, $P = 0.009$).

Conclusion: This analysis identifies increased tear proteins which have previously been associated with oxidative stress (plasma Ceruloplasmin), neuropathy (plasma Cystatin-C). It also identifies reduced expression of complement C3, and vonWillebrand protein which may be relevant to neuropathy as both show increased deposition in blood vessels of patients with neuropathy. However, this analysis fails to show significant differences in a range of neurotrophins and growth factors which have previously been implicated in nerve damage, despite significant corneal nerve damage observed via CCM. It also reveals potentially new candidates and target pathways for future study and intervention in diabetic neuropathy.

1135

Factors influencing pain experience in patients with diabetic neuropathy
L. Vileikyte¹, J.S. Gonzalez², A.J.M. Boulton¹;

¹Medicine, University of Manchester, UK, ²Psychology, Yeshiva University, Bronx, USA.

Background and aims: While the impact of diabetic painful neuropathy (DPN) on individuals' functioning and quality of life is well researched, factors influencing DPN experience are poorly understood. This study of patients with diabetic neuropathy, DN ($n = 346$; age 61.2 ± 10.8 ; 71% male; 73% type 2 DM) examined the cross-sectional and longitudinal (baseline-18 months) associations of demographic, disease and psychological factors to DPN.

Materials and methods: DPN symptom severity was assessed with a 7-item NeuroQoL-pain scale by patient self-report (2.9 ± 0.8); the Neuropathy Disability Score, NDS (total score: 7.4 ± 2.2) assessed the clinical signs of small (pain and temperature) and large (vibration and Achilles reflexes) sensory-motor fiber dysfunction; Sleep Impairment was measured with 1-item from NeuroQoL scale. Psychological self-report instruments included: the Hospital Anxiety and Depression Scale, HADS, measuring anxiety HADS-A and depression HADS-D; the Big Five Inventory, BFI, a personality measure assessing neuroticism, openness, agreeableness, conscientiousness, extraversion, and Illness Perception Questionnaire-Revised, IPQ-R, adapted to DN to assess specific cognitions of chronic timeline, unpredictable course, consequences, treatment and personal control. Multivariate linear regression tested relationships between baseline predictors in three models of DPN severity: (1) baseline, (2) follow-up, and (3) change in DPN over time.

Results: BFI-neuroticism emerged as the only personality characteristic with significant cross-sectional and longitudinal relationships to DPN severity. However, these relationships were reduced to non-significance by the addition of HADS-A and HADS-D. The temperature component of NDS was a significant positive predictor of DPN severity cross-sectionally and longitudinally, but these relationships were reduced to non-significance by the addition of HADS-D. (1) In the cross-sectional model, factors independently associated with more severe DPN were HADS-A ($\beta = 0.13$; $p = 0.020$); HADS-D ($\beta = 0.16$; $p = 0.002$); Sleep Impairment ($\beta = 0.47$; $p < 0.001$) and IPQ-R symptom unpredictability ($\beta = 0.15$; $p = 0.001$). (2) The longitudinal model was largely consistent with baseline results with younger age ($\beta = -0.10$; $p = 0.04$); HADS-A ($\beta = 0.17$; $p = 0.007$); Sleep Impairment ($\beta = 0.39$; $p < 0.001$) and IPQ-R symptom unpredictability ($\beta = 0.1$; $p = 0.026$) as independent predictors of DPN at 18 months. The strongest longitudinal predictor of DPN was baseline pain severity ($\beta = 0.72$; $p < 0.001$), explaining 62% of the variance in DPN at 18 months. (3) Change-based analyses, controlling for baseline DPN, showed that younger age ($\beta = -0.09$; $p = 0.025$) and higher levels of HADS-A

($\beta = 0.09$; $p = 0.021$) were the only significant predictors of increments in DPN over time.

Conclusion: These data suggest that although pain experience in diabetic neuropathy is consistently accompanied by depression, sleep impairment, and negative cognitive appraisals, these factors are unlikely to be causally related to pain. The most important predictor of pain over time is baseline pain severity. Anxiety may also play a causal role. Pain management in patients affected by diabetic neuropathy should therefore target both pain intensity and anxious mood.

1136

Phantom limb pain with diabetic amputation is no different to that of non-diabetic amputation

R.L. Clark¹, F.L. Bowling², F. Jepson¹, S. Rajbhandari¹;

¹Lancashire Teaching Hospitals, Preston, ²University of Manchester, UK.

Background and aims: There is a commonly-held belief that diabetic amputees experience less phantom limb pain (PLP) than non-diabetic amputees because of the effects of diabetic peripheral neuropathy. The aim of our study was to validate or refute this belief; we did this by examining the effects of diabetes on the prevalence, severity and characteristics of PLP and phantom sensations. We also explored the relationship between PLP and stump pain, and attempted to determine whether PLP had any effect on mobility.

Materials and methods: We used a customized postal questionnaire to collect information about amputees' experiences of phantom limb pain. Using the patient database from a UK regional centre for mobility rehabilitation (Lancashire Teaching Hospitals), we sent the questionnaire to 200 of the most recent lower limb amputees receiving mobility rehabilitation.

Results: From the 200 questionnaires sent, we received 102 complete responses; there were 11 respondents with amputations on both legs (who completed two questionnaires), therefore the total number of accounts of PLP was 113. Of these 113 accounts of PLP, there were 16 instances of recent trauma to the amputation stump. Limbs with recent stump trauma produced significantly higher average phantom limb pain scores (5.69 ± 0.59 out of 10 on a numerical pain scale), compared to limbs with no recent stump trauma (4.13 ± 0.29) ($p = 0.0416$). When comparing PLP prevalence and severity between the diabetic and non-diabetic groups, we excluded limbs with recent stump trauma to prevent this variable from skewing the results. Forty-four (50%) of the amputees without recent stump trauma reported that they had diabetes mellitus (DM group), while forty-four (50%) reported that they were non-diabetic (ND group). Some degree of PLP was reported in 85.6% of amputated limbs, and there was no difference in the prevalence of PLP when comparing the DM group (prevalence = 82.0%) and the ND group (prevalence = 89.4%) ($p = 0.391$). Phantom sensations were reported in 68.0% of amputated limbs, and similarly there was no difference in the prevalence of phantom sensations when comparing the DM group (66.0%) and ND group (70.2%) ($p = 0.665$). The average intensity of PLP was $3.89 (\pm 0.40)$ for the DM group and $4.38 (\pm 0.41)$ for the ND group, this was not a statistically significant difference ($p = 0.402$). To assess the impact of PLP on mobility, we asked "does phantom limb pain ever stop you walking?" The mean phantom limb pain score of the group which answered "yes" to this question was significantly higher than the remainder of the respondents, at $7.04 (\pm 0.61)$ and $3.39 (\pm 0.34)$ respectively. This difference was highly significant ($p < 0.001$).

Conclusion: Despite the common belief regarding a relationship between diabetes and phantom limb pain, we could find no evidence that diabetes has any effect on the prevalence or severity of PLP. This may be because the pathological process behind the development of PLP occurs primarily in the central nervous system. We did, however, corroborate previous evidence that phantom limb pain severity has a relationship to stump pain, by showing that people with recent stump trauma had a higher average phantom limb pain score. We were also able to show that amputees with high average phantom limb pain scores were significantly more likely to have their walking affected than those with low pain scores; this is an important result, as it stresses the value of aggressively treating phantom limb pain during mobility rehabilitation.

1137

Sensory profiles of neuropathic pain in painful diabetic polyneuropathy
V. Spallone¹, R. Morganti¹, C. Greco¹, C. D'Amato¹, L. Cacciotti¹, S. Rotella¹, G.A. Marfia²;

¹Internal Medicine, ²Neurological Sciences, Tor Vergata University, Rome, Italy.

Background and aims: The identification of distinct sensory profiles of neuropathic pain in painful diabetic polyneuropathy (PDPN) that reflect the underlying pain-generating mechanisms, can support a mechanism-based individual therapeutic approach. The aim of this study was to describe the characteristics of neuropathic pain and to determine whether specific sensory profiles are identifiable in PDPN using screening and assessment tools of neuropathic pain.

Materials and methods: In 59 patients with clinical diagnosis of PDPN, Michigan Neuropathy Screening Instrument Questionnaire, Michigan Diabetic Neuropathy Score (MDNS), Vibration Perception Threshold (VPT), Cold (CTT) and Warm Thermal Threshold (WTT), Nerve Conduction Studies (NCS), Douleur Neuropathique en 4 Questions (DN4), and Neuropathic Pain Symptom Inventory (NPSI) were performed.

Results: Paresthesia/dysesthesia (tingling and pins and needles) and burning were the most frequent sensory descriptors reported by the patients on NPSI (96% and 87%, respectively), followed by paroxysmal pain (electric shock and stabbing), evoked pain (by brushing, pressure and cold), and deep pain (squeezing and pressure) (77%, 69%, and 67%, respectively). The highest scores were reached by NPSI dimensions of burning (5.4±2.9) and paresthesia/dysesthesia (4.9±2.5), the lowest scores by evoked pain (2.1±2.1). When looking for an internal association among the sensory descriptors of DN4 or NPSI, an association was found between electric shock and pins and needles ($\chi^2=4.60$, $P=0.032$) and between tingling and itching on DN4 ($\chi^2=5.11$, $P=0.016$), between burning pain and deep pain ($\chi^2=5.36$, $P=0.012$) and between evoked pain and paroxysmal pain ($\chi^2=5.15$, $P=0.022$) on NPSI. When looking for neurological correlates of the pain descriptors, we found that DN4 burning was associated with higher sural amplitude z score (-0.98 ± 1.19 Vs -2.41 ± 0.59 , $P=0.020$), DN4 tingling with a lower number of NCV abnormalities (4.61 ± 3.22 Vs 9.27 ± 6.87 , $P=0.007$), DN4 numbness with higher VPT (28.42 ± 11.23 Vs 19.24 ± 7.4 , $P=0.004$), and DN4 prick hypoesthesia with higher MDNS (15.00 ± 5.32 Vs 8.24 ± 4.37 , $P<0.0001$), higher WTT (42.60 ± 5.11 Vs 39.26 ± 3.84 , $P=0.022$), lower CTT (22.28 ± 8.78 Vs 26.78 ± 3.97 , $P=0.017$), and lower peroneal conduction velocity z score (-2.45 ± 0.53 Vs -1.17 ± 1.46 , $P=0.021$). NPSI burning was associated with higher CTT (26.37 ± 4.05 Vs 20.22 ± 11.52 , $P=0.014$), whereas NPSI evoked pain subscore with lower sural amplitude z score (-1.70 ± 1.05 Vs -0.07 ± 1.19 , $P=0.029$). NPSI deep pain subscore was positively related to VPT ($\rho=0.32$, $P=0.032$) and inversely related to tibial motor amplitude z score ($\rho=-0.53$, $P=0.009$); NPSI paresthesia/dysesthesia subscore was positively related to VPT ($\rho=0.30$, $P=0.039$) and inversely related to peroneal nerve amplitude z score ($\rho=-0.51$, $P=0.011$).

Conclusion: A sensory profile of burning pain and paresthesia is prevalent in PDPN patients, however, other combinations of symptoms can occur, i.e. burning pain with deep pain and allodynia with paroxysmal pain. Although the suggestion that burning pain - and not evoked pain - might be associated with preserved nerve function, identification of neurological correlates of different sensory profiles in PDPN remains unachieved.

1138

A functional magnetic resonance imaging study of central pain processing of co-existing depression in painful diabetic neuropathy

J. Davies¹, D. Selvarajah¹, A. Sankar¹, E. Cachia¹, I. Tracey², I. Wilkinson¹, S. Tesfaye¹;

¹Diabetes Research Unit, University of Sheffield, ²FMRIB, Oxford University, UK.

Background and aims: Painful diabetic polyneuropathy (painful DPN) is a distressing and disabling condition that negatively impact on quality of life. The relationship between chronic pain and depression has been well documented in painful DPN with significant association between depression, anxiety and pain catastrophising behaviour. Pain perception is a subjective experience and can be modulated by various factors including mood disturbance. A heightened response is seen in emotional/affective brain processing structures in chronic pain patients however the exact influence of mood disturbance on pain processing in DPN is still poorly understood.

Methods: 19 right-handed subjects with painful-DPN underwent neurophysiological assessments. All subjects had neuropathic pain below the knees [mean-Likert 7.5(1.8)]. Depression assessed using the Hospital Anxiety and Depression Scale (HADS-D). Depressed patients $n=12$, non depressed $n=7$. Together with 15 age-matched healthy volunteers (HV), all subjects underwent functional magnetic resonance imaging (fMRI) during noxious heat pain application to the thigh (non-neuropathic region) versus pain-free baseline thermal stimulation in a 'boxcar' paradigm. MR examinations were performed on a 3T Phillips Acheiva. Images were analysed using SPM5 (www.fil.ion.ucl.ac.uk/SPM5).

Results: Patients with painful DPN showed an increased stimulus response in the prefrontal cortex (PFC) (Talairach coordinates 18, 40, 14mm; $p<0.001$ uncorrected) and anterior cingulate cortex (ACC, 20 32 20mm) compared to HV ($p<0.001$ uncorrected). Greater activation was seen in the cingulate cortex in painful DPN patients with depression compared to those without (-12, 4, 3 0 mm; $p<0.001$ uncorrected). No clusters of activation seen in non-depression vs. depression. A greater response was seen in the posterior cingulate cortex (16 -40 12mm; $p<0.001$ uncorrected) and parahippocampal gyrus (-36, -46, -6mm; $p<0.001$ uncorrected) in depressed vs. non-depressed patients using HADs anxiety score (HADS-A) as a covariate.

Discussion: Our results suggest the cingulate gyrus plays an important role in modulating pain perception in mood disorders. Whilst the anterior cingulate has a role in emotional processing the posterior cingulate is often characterised as 'evaluative' and associated with memory through its connections with the hippocampus. Constant interruption of neuropathic pain in patients with coexisting depression results in significant emotional distress. This may explain the increased activation of the anterior cingulate cortex. Patients with anxiety report greater number of painful symptoms and pain intensity this may be mediated by increased activation of the posterior cingulate cortex and parahippocampus. Using this novel technique we are gaining new insights into brain regions involved in abnormal pain processing in DPN and the pain modulating effects of mood disorders which may lead to potentially new targets for future therapies and pain management strategies.

Neuropathic pain severity relates to important patient related health outcomes: implications for effective early management of painful diabetic neuropathy

T. Cash, D. Selvarajah, A. Roddick, R.S. Gandhi, S. Tesfaye;
Diabetes Research Unit, Royal Hallamshire Hospital, Sheffield, UK.

Background and aims: It is well recognised that chronic painful diabetic peripheral neuropathy (painful-DPN) results in immense loss of quality of life and significant disability. However, the relationship between pain severity and important health related outcomes is less clearly defined. The goal of this study was to assess the impact of neuropathic pain severity on mood, functionality, sleep and quality of life in patients with painful-DPN.

Materials and methods: 300 patients with the diagnosis of painful-DPN were identified from the Sheffield Teaching Hospitals diabetes register. From this pool, 44 patients (mean age, 61.5 ± 10.52 , 25 males, 10 with Type 1 diabetes and neuropathic pain duration of, 9.5 ± 6.33) have so far undergone assessment of: 1) peripheral neuropathy using Neuropathic Disability Score, 2) pain severity using the Modified Brief Pain Inventory (m-BPI-DPN) and the Neuropathic Pain Scale (NPS), 3) quality of life (QoL) and functionality using the DPN specific, Norfolk QoL Scale, 3) mood using Hospital Anxiety and Depression Scale (HADS) and 4) sleep quality and duration.

Results: Based on the m-BPI-DPN scores patients were divided into mild (score of 0-3), moderate (4-6) and severe (7-10) painful-DPN groups. With increasing pain severity significant differences (one way ANOVA) between the groups were found for: number of prescription medications ($p=0.046$), general activity ($p=0.01$), interference with work activity ($p=0.001$), walking ability ($p=0.004$), Norfolk QoL Scale ($p=0.043$) and sleep interruption ($p=0.026$). However, there was a high prevalence of anxiety and/or depression (61.5%) regardless of pain severity in this cohort of patients.

Conclusion: These findings demonstrate that neuropathic pain severity is associated with worse outcomes for important patient related outcomes including functionality, QoL and sleep quality. Therefore, early identification of painful-DPN patients and effective management of pain is crucial to combat the debilitating burden of painful-DPN.

Amitriptyline versus alpha-lipoic acid in the treatment of painful diabetic polyneuropathy

A. Psurek, M. Wróbel, A. Szymborska-Kajaneck, D. Rokicka, W. Grzeszczak, K. Strojek;

Department of Internal Medicine, Diabetology and Nephrology, Medical University of Silesia, Zabrze, Poland.

Background and aims: Painful diabetic polyneuropathy is a serious health problem. There is a need of a medication that is well tolerated and which provides meaningful pain relief and improved quality of life. The aim of this study was to compare the efficacy and safety of alpha-lipoic acid and amitriptyline in alleviating pain associated with diabetic polyneuropathy.

Materials and methods: In this randomized, single-blind, clinical trial 32 patients with diabetic polyneuropathy who had a pain score of at least 40 mm in a 0–100 mm VAS scale, were assigned to sequential treatment with 600 mg alpha-lipoic acid once daily intravenously and placebo orally for 3 weeks or to treatment with amitriptyline orally, at doses of 25, 50 and 75 mg and placebo intravenously for 3 weeks. The treatment was followed in ambulatory for 3 months. Patients continued the treatment with the same drug orally in previously established doses. Pain relief (SFMPQ-VAS), quality of life improvement (EuroQol EQ-5D) and occurrence of adverse events were assessed weekly during hospitalization and monthly when treated in outpatient.

Results: Upwards 50% VAS reduction was noted in 7 (44%) patients on alpha-lipoic acid and 6 (38%) patients on amitriptyline ($P = \text{ns}$). A comparable reduction in pain intensity was obtained with both drugs from the first week on ($\Delta\text{VAS} -13 \pm 13$ mm vs. -13 ± 14 mm, $P = 0.94$, respectively). The improvement in quality of life was significantly higher in patients treated with amitriptyline after 1 and 3 weeks of the observation when compared to alpha-lipoic acid (respectively: $\Delta\text{EQ}_{1\text{week}} -1 \pm 10$ vs. 9 ± 13 , $\text{EQ}_{3\text{week}} 12 \pm 20$ vs. 28 ± 21 , $P < 0.05$). The adverse events were reported only with amitriptyline, dry mouth being the most common.

Conclusion: Amitriptyline and alpha-lipoic acid is similarly effective in the treatment of painful diabetic polyneuropathy. Amitriptyline has greater beneficial impact on the quality of life, but is associated with a higher risk of adverse effects.

Reduced heart rate variability in youth with type 1 diabetes: the SEARCH CVD Study

D. Dabelea¹, M. Jaiswal¹, E.M. Urbina², J. Talton³, P.R. Wadwa⁴, L.M. Dolan⁵, R.F. Hamman¹, S.R. Daniels⁶, S. Marcovina⁷;

¹Epidemiology, Colorado School of Public Health, Aurora, ²Cincinnati Children's Hosp.Med.Ctr., ³Wake Forest University School of Medicine, Winston-Salem, ⁴Pediatrics, Barbara Davis Center, Aurora, ⁵Cincinnati Children's Hosp.Med.Ctr., ⁶Pediatrics, The Children's Hospital, Aurora, USA, ⁷Northwest Lipid Laboratory, Seattle, USA.

Background and aims: Reduced heart rate variability (HRV) is the earliest sign of cardiac autonomic neuropathy (CAN), a major diabetes complication. We examined differences in HRV markers reflecting early (parasympathetic loss with sympathetic override) or more advanced (sympathetic and parasympathetic loss) subclinical CAN in 237 youth with T1D (age 19.5 ± 2.8 years, T1D duration 10.1 ± 3.9 years) compared to 125 non-diabetic control subjects (age 19.2 ± 3.0 years) who participated in the SEARCH CVD study in Colorado and Ohio.

Materials and methods: Resting HRV measures were obtained using the SphygmoCor Vx (AtCor Medical, Lisle, IL). Body mass index (BMI), blood pressure (BP), fasting lipids (LDL and HDL-cholesterol, triglycerides) and hemoglobin A1c were measured. General linear models were used to explore group differences (T1D vs. controls) in measures of HRV, after adjustment for covariates.

Results: Older age, male sex, higher LDL-cholesterol and triglyceride levels were consistently associated with worse HRV parameters, regardless of case/control status. Compared with controls, T1D youth had lower HRV parameters in both time [standard deviation of normal RR intervals (SDNN), root mean square successive difference (RMSSD), percent of normal RR intervals less than 50 msec (pNN50)] and frequency domains [low and high frequency power (LF, HF)], even after adjustment for age, sex, race, BMI, BP and lipid levels (Table). On further adjustment for A1c, all differences became non-significant. A pattern of combined parasympathetic and sympathetic loss (reduced pNN50, RMSSD, HF with higher LF: HF ratio) reflecting a more advanced CAN stage was evident in T1D youth.

Conclusion: These findings advocate for CAN screening in youth with T1D and suggest the need for improved glycemic control to prevent the development and progression of CAN.

Adjusted HRV parameters among T1D and controls*

HRV parameters	T1D	Controls	p-value
SDNN (msec)	63.3	76.3	0.002
RMSSD (msec)	59.2	75.2	0.002
pNN50 (%)	41.5	47.1	0.03
HF power (Hz)	56.4	61.3	0.04
LF: HF ratio	1.11	0.82	0.06

* Adjusted for age, sex, race, BMI, BP, LDL-cholesterol, HDL-cholesterol and triglyceride levels

Spectral analysis of heart rate variability: an early biomarker of cardiac autonomic neuropathy?

R.S. Gandhi¹, T. Cash¹, D. Selvarajah¹, J.L.B. Marques^{1,2}, T. Hughes¹, S. Tesfaye¹;

¹Diabetes Research Unit, Royal Hallamshire Hospital, Sheffield, UK,

²Institute of Biomedical Engineering, Federal University of Santa Catarina, Florianopolis, Brazil.

Background and aims: Cardiac autonomic neuropathy (CAN) is a serious complication of diabetes and carries up to a five-fold increased risk of mortality. However, early detection of CAN is problematic since conventional autonomic function tests (AFT) are cumbersome and are not feasible in busy diabetes clinics. The aim of this ongoing study is to assess the diagnostic util-

ity of spectral heart rate variability (SHRV), which is a simple 5-minute test, as an early biomarker of CAN. Early detection of this disorder might lead to a better prognosis by the deployment of multi-factorial interventions which may slow or even reverse its progression.

Materials and methods: At baseline, 130 type 1 diabetes (T1DM) subjects underwent SHRV, baroreceptor sensitivity testing (BRS) and AFT (O'Brien's protocol). Based on the results of these tests patients were divided into no-CAN (normal BRS and AFT), subclinical-CAN (normal AFTs but abnormal BRS) and established-CAN (abnormal AFT and BRS). Using a discriminant function analysis model, we were able to correctly classify 79% of cases using only SHRV parameters. Having excluded those with established disease at baseline, 20 subjects (11 with subclinical-CAN and 9 with no-CAN) have thus far undergone the same autonomic function tests (AFT, BRS and SHRV). The mean follow-up period was 2.95 ± 0.7 years. HbA1c at initial and follow-up visit was 8.7 ± 0.39 and $8.6 \pm 0.26\%$ respectively. There were no significant changes in the use medications that would alter autonomic function between the two study periods.

Results: Three subjects with subclinical-CAN progressed to develop established-CAN (27.3% incidence rate). No subjects with no-CAN developed established-CAN over this period. There was a trend for deterioration in SHRV parameters in all subjects [mean change from baseline TP $0.09(0.52)$]. SDNN deterioration was greater in the subclinical-CAN group compared to no-CAN [subclinical-CAN vs no-CAN; $0.03(0.10)$ vs $-2.86(0.31)$; Mann-Whitney $p < 0.001$]. Subjects with subclinical-CAN who progressed to develop established-CAN demonstrated much greater deterioration in TP and SDNN compared to those who did not [TP $0.24(0.28)$ vs $-0.007(0.23)$ and SDNN $0.05(0.13)$ vs $0.02(0.10)$ respectively].

Conclusion: The preliminary results of this ongoing prospective study show an incidence for established-CAN in subjects with subclinical-CAN of 27.3% over the follow-up period. There was also a general deterioration in SHRV measures over time and this decline was most pronounced in subclinical-CAN subjects, especially those who progressed to develop established-CAN. SHRV, a simple, non-invasive and quick bedside 5-minute test that is feasible in the context of a busy diabetes clinic and seems to be an early biomarker for the development of clinically significant CAN.

Cardiovascular autonomic neuropathy and subclinical cardiovascular disease in normoalbuminuric type 1 diabetic patients

U.M. Mogensen¹, T. Jensen², A.S. Matthiesen², L. Køber¹, H. Kelbæk¹, U. Diken³, P. Rossing⁴, J. Hilsted², K.F. Kofoed^{1,5};

¹Department of Cardiology, University Hospital Rigshospitalet, Copenhagen,

²Department of Endocrinology, University Hospital Rigshospitalet,

Copenhagen, ³Department of Cardiology, University Hospital Hvidovre,

Copenhagen, ⁴Steno Diabetes Center, Gentofte, ⁵Department of Radiology,

University Hospital Rigshospitalet, Copenhagen, Denmark.

Background and aims: Cardiovascular autonomic neuropathy (CAN) is associated with increased morbidity and mortality in diabetes. The underlying mechanisms are largely unknown. The aim of the present study was to investigate the potential association between CAN and subclinical coronary atherosclerosis and prognostic markers of cardiac disease in asymptomatic normoalbuminuric type 1 diabetic patients.

Materials and methods: Fifty-six normotensive, normoalbuminuric, type 1 diabetic patients were divided into 26 with (+) and 30 without (-) CAN according to tests of their autonomic nerve function. Coronary artery plaque burden and calcium score (CACS) were evaluated using multislice computed tomography. Left ventricular function was evaluated with Tissue Doppler Imaging (TDI) echocardiography. Blood pressure and electrocardiography were recorded through 24 hours to evaluate nocturnal drop in blood pressure (dipping), pulse pressure and ventricular ectopia.

Results: In patients +CAN compared to -CAN there was a trend towards a higher prevalence of coronary plaques and flow limiting stenosis (24% vs. 10%), but this was not significant. However, in +CAN the CACS was significantly higher (median±range) (197 (0–5552) vs. 5 (0–312), $P=0.0012$) and only patients +CAN had CACS >400 ($n=9$ vs. $n=0$, $p=0.0004$), a value strongly associated with increased risk of cardiovascular disease. TDI of mitral annular motion showed a decrease in both early diastole (e') (7.9 (5–11) vs. 9.8 (8–13) cm/s, $p=0.0007$) and in systole (s') (7.0 (6–11) vs. 8.1 (6–11) cm/s, $p=0.028$) in +CAN compared to -CAN, demonstrating subclinical impairment in left ventricular diastolic and systolic function. Non-dipping was more prevalent (73% vs. 37%, $p=0.02$) and pulse pressure was increased (mean±standard de-

viation) (58 ± 9 vs. 46 ± 9 mmHg, $p < 0.0001$) in +CAN compared to -CAN. In multivariable analysis including age, sex, diabetes duration, HbA1c, BMI, total cholesterol and smoking, CAN was an independent predictor of increased CACS, subclinical left ventricular dysfunction, increased pulse pressure and ventricular ectopia.

Conclusion: CAN in asymptomatic normoalbuminuric type 1 diabetic patients is associated with distinct signs of subclinical cardiovascular disease. Although such findings do not explain the excess mortality reported in CAN, they do identify pathophysiological mechanisms which - if uninterrupted - could cause clinically evident cardiovascular disease.

Effect of cardiovascular autonomic neuropathy on hypoglycaemia unawareness, QTc interval and exercise tolerance in type 1 diabetes mellitus

O.V. Svetlova, I.V. Gurieva;

Federal Bureau of Social and Medical Expertise, Moscow, Russian Federation.

Background and aims: The patients of type 1 DM with cardiovascular autonomic neuropathy (CAN) have a more risk of prolonged QTc, exercise intolerance, sudden death and poor hypoglycemic sympatho-adrenal responses. We investigated the influence of diabetic autonomic dysfunction on QTc lengthening, exercise tolerance in type 1 DM with hypoglycemia unawareness.

Materials and methods: The 80 DM1 patients (35.7 ± 1.3 y.o.) were submitted to CGM during 72-h. CAN was assessed by five cardiovascular autonomic tests by Ewing; QTc and QTcd were measured before and after treadmill. Treadmill was performed using Gardner protocol in 46 patients.

Results: Patients were divided into 3 groups: 1 - with symptomatic hypoglycemia (42,5%), 2 - with 1-2 episodes of hypoglycemia unawareness (35%), 3 - with 3 and more episodes of hypoglycemia unawareness (22,5%) during CGM time. Presence of CAN was 73 (91,25%) patients. CAN differed statistically between 1 and 2(3) groups ($p < 0,01$). Relation between CAN and hypoglycemia unawareness ($r=0,76$, $p < 0,001$), CAN and QTc ($r=0,73$, $p < 0,01$) were found. CAN differed before and after treadmill in every group and was greater after treadmill ($p < 0,01$). QTc showed a significant correlation with hypoglycemia unawareness ($r=0,71$, $p < 0,001$). QTc and QTcd were increased in 3rd group ($447,1 \pm 2,3$ ms and $106,8 \pm 34,6$ ms). After treadmill QTc differed between 1(2) and 3rd group ($p < 0,001$) and prolongation of QTc increased after exercise test. QTcd increased in 2nd and 3rd groups after treadmill.

Conclusion: CAN is related to prolonged QTc and QTcd. The patients with hypoglycemia unawareness characterized significant prevalence of autonomic dysfunction, exercise intolerance, prolonged QTc, QTcd.

1145

Heart rate variability is severely impaired among type 2 diabetic patients with hypertension

I. Istenes, Z. Putz, K. Keresztes, T. Martos, N. Németh, A.E. Körei, R. Haraszti, P. Vargha, P. Kempler;

Ist Dept. of Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: Cardiovascular autonomic neuropathy is a common complication of diabetes mellitus and it may be present among patients with essential hypertension as well. The aim of our study was to assess heart rate variability among Type 2 diabetic patients with and without hypertension and in hypertensive patients without diabetes.

Materials and methods: Fourty type 2 diabetic, normotensive patients (mean age: $52,8 \pm 8,1$ years) 63 type 2 diabetic patients with hypertension (mean age: $55,2 \pm 6,5$ years), 74 nondiabetic patients with essential hypertension (mean age: $53,0 \pm 12,1$ years), and 25 healthy control subjects (mean age: $52,2 \pm 9,2$ years) were studied. Autonomic function was evaluated by 24 hour heart rate variability (HRV) measurement. HRV was characterized by the triangular index value (HRVti) and by the spectral components of the frequency domain analysis: the low (LF) and the high frequency (HF) components and the total power (TP).

Results: According to the two-factor analysis of variance, hypertension and diabetes were independently associated with diminished heart rate variability and their effects proved to be additive. All HRV parameters were diminished

in Type 2 diabetic patients with and without hypertension and in hypertensive diabetic patients compared to healthy control subjects, but significant difference was found only between Type 2 diabetic patients with hypertension and healthy controls. (mean±SD/ TP: 3 ± 0.4 vs. 3.4 ± 0.25 ms² $p<0.001$, LF: 2.3 ± 0.51 vs. 2.87 ± 0.28 ms² $p<0.0001$, HF: 1.96 ± 0.4 vs. 2.4 ± 0.43 ms² $p<0.01$, HRVti: 1.38 ± 0.18 vs. 1.51 ± 0.23 $p<0.05$, respectively). Moreover, the HRV parameters of Type 2 diabetic patients with hypertension were significantly diminished compared to hypertensive patients without diabetes. (TP: 3 ± 0.4 vs. 3.27 ± 0.33 ms² $p<0.001$, LF: 2.3 ± 0.51 vs. 2.68 ± 0.32 ms² $p<0.0001$, HF: 1.96 ± 0.4 vs. 2.3 ± 0.42 ms² $p<0.001$, HRVti: 1.38 ± 0.18 vs. 1.51 ± 0.14 $p<0.001$, respectively). Furthermore, the low frequency component, which is one of the most reliable predictors of poor prognosis, was significantly lower in the diabetic patients with hypertension compared to diabetic patients without hypertension. (2.3 ± 0.51 vs. 2.59 ± 0.5 ms² $p=0.01$).

Conclusion: Diabetes seems to have a greater impact on autonomic dysfunction compared to hypertension. Patients suffering from both diabetes and hypertension are at the highest risk of reduced heart rate variability. Early assessment of the autonomic nerve function is suggested being performed among diabetic patients with hypertension.

1146

Relation between sleep-disordered breathing and cardiac autonomic neuropathy in non-obese Japanese subjects with type 2 diabetes

K. Nomura, H. Ikeda, Y. Hamamoto, S. Honjo, Y. Kawasaki, Y. Wada, K. Mori, H. Koshiyama;
The Center for Diabetes & Endocrinology, Medical Research Institute Kitano Hospital, Osaka, Japan.

Background and aims: Although obesity is a major risk factor for sleep-disordered breathing (SDB), many Japanese subjects with diabetes are less obese than Caucasians. We evaluated the relationship between SDB and clinical parameters, especially in relation to cardiac autonomic neuropathy (CAN) in Japanese subjects with type 2 diabetes.

Materials and methods: The study included a total of 261 consecutive Japanese subjects with type 2 diabetes (161 men and 100 women, aged 40–79 years) including nonobese subjects (defined as body mass index (BMI) <25 kg/m² for Japanese) (n=141). SDB was defined by 4% oxygen desaturation index (ODI) level of 5 or more events per hour, which was measured by nocturnal pulse oximetry. CAN was examined with the variation of R-R intervals (CVRR).

Results: The patients with SDB were 24.5 and 16.3% of total subjects and nonobese diabetic subjects, respectively. The nonobese subjects with SDB had significantly lower coefficient of CVRR than those without SDB. Multiple regression analysis revealed that BMI and heart rate were significant independent factors for SDB as a whole, but CVRR was the only independent factor for SDB in nonobese subjects with type 2 diabetes.

Conclusion: SDB is highly prevalent in Japanese subjects with type 2 diabetes, even in nonobese ones, and that CAN is associated with SDB.

1147

Elevation of serum high molecular weight adiponectin in patients with type 2 diabetes and orthostatic hypotension: association with arterial stiffness and hypercoagulability

Y. Aso, T. Terasawa, R. Naruse, K. Hara, K. Takebayashi, T. Inukai;
Medicine, Dokkyo University School of Medicine, Koshigaya Hospital, Japan.

Background and aims: Orthostatic hypotension (OH) is a hallmark of diabetic autonomic neuropathy and is associated with increased mortality. The serum level of adiponectin is elevated in patients with heart failure or renal failure. In the present study, we measured serum levels of total and high molecular weight (HMW) adiponectin in patients with type 2 diabetes and OH. We also investigated the relationship between the presence of OH and various clinical parameters in patients with type 2 diabetes.

Materials and methods: We studied 105 patients with type 2 diabetes. OH was defined as a decrease of 20 mmHg or more in systolic blood pressure (BP) and/or 10 mmHg in diastolic BP when BP was measured for 3 minutes while standing. The brachial-ankle pulse wave velocity (baPWV) was also measured as an index of arterial stiffness.

Results: OH was found in 30 patients with diabetes (28.6%). The hematocrit and estimated glomerular filtration rate were significantly lower in patients

with OH than in those without it. BaPWV and serum total and HMW adiponectin were significantly higher in patients with OH than in those without it. Furthermore, the HMW/total adiponectin ratio was higher in patients with OH than in those without it and hypertension was more common in patients with OH. Plasma prothrombin F1+2, a coagulation maker, was higher in patients with OH than in those without it, while there were no differences of fibrinolytic markers between the two groups. Multivariate analysis showed that HDL cholesterol, hematocrit, F1+2, baPWV, and a decline of systolic BP on standing were independent determinants of HMW adiponectin.

Conclusion: Patients with type 2 diabetes and OH had an elevated serum level of HMW adiponectin, which was associated with the simultaneous presence of renal dysfunction, anemia, arterial stiffness, and hypercoagulability.

1148

Application of thioctic acid in type 2 diabetic patients with cardiovascular autonomic neuropathy and chronic heart failure

I. Pochinka, J. Struchkova, L. Strongin;
The Nizhny Novgorod State Medical Academy, Russian Federation.

Background and aims: Cardiovascular autonomic neuropathy seems one of the pathogenetic factors of heart failure in diabetic patients. Thioctic acid proves efficiency in treatment of diabetic neuropathy. It has to be checked whether thioctic acid can prevent deterioration of heart failure in diabetic patients with cardiovascular autonomic neuropathy.

Materials and methods: Open prospective controlled randomized study was performed. 50 type 2 diabetic patients with cardiovascular autonomic neuropathy and chronic heart failure were included. SDNN < 33 ms (in the research of heart rate variability at 5-minute registration of an electrocardiogram in rest in patients with sinus rhythm) was regarded as criterion of cardiovascular autonomic neuropathy. The severity of heart failure was estimated by a 6-minute walk test and by the echocardiography. Glycemic control was also searched. Patients were randomized into 2 groups (27 patients in the group of intervention and 23 in the group of control). Oral thioctic acid 600 mg every day in the course of 3 months was prescribed for patients from group of intervention only. The patients of both groups were examined in 3 and 6 months after including in study. The results are presented in median and interquartile range.

Results: Level of SDNN rose in the group of intervention: 18 ms [15; 22] on basic visit, 28 ms [19; 35] in 3-d month, and 30 ms [14; 36] in 6-th month ($p < 0.001$, Friedman ANOVA). Level of SDNN in the group of control was reduced: 18 ms [14; 26] - 15.5 ms [11; 23] - 13 ms [11; 19] ($p < 0.001$, Friedman ANOVA). We did not find significant changes of glycated hemoglobin and parameters of echocardiography in both groups during 3 and 6 months. Results of a 6-minute walk test significantly went down only in control group: from 295 m [180; 324] on basic visit to 274 m [220; 294] in 3-d month, and up to 240 m [180; 299] in 6-th month ($p=0.02$, Friedman ANOVA). In contrast to control, there was not significant reduction in results of a 6-minute walk test in the group of intervention: 295 m [178; 316] - 286 m [202; 345] - 273 m [166; 370] ($p = 0.5$, Friedman ANOVA).

Conclusion: Thioctic acid 600 mg per os every day in the course of 3 months in type 2 diabetic patients with cardiovascular autonomic neuropathy and chronic heart failure improves parameters of heart rate variability and has a beneficial influence on tolerance to physical exercise.

PS 104 Autonomic neuropathy and sexual dysfunction

1149

Decreased baroreflex gain more strongly predicts microalbuminuria and increased pulsatile stress than decreased RR E/I ratio in patients with type 1 diabetes

A.J.L. Scheen, M. Marchand, J.-C. Philips;

Division of Diabetes, Nutrition and Metabolic Disorders, CHU Sart Tilman, Liege, Belgium.

Background and aims: Long-lasting type 1 diabetes (T1DM) may be associated with cardiac autonomic neuropathy (CAN), increased pulse pressure (PP) or pulsatile stress, and microalbuminuria (μ A), all cardiovascular risk factors. We compared the relationships of two markers of CAN, RR E/I (Expiratory/Inspiratory) ratio and baroreflex gain (BRG), with μ A and pulsatile stress during an active orthostatic test in patients with T1DM.

Materials and methods: 167 patients with T1DM (mean age 40 years, diabetes duration 20 years, body mass index 23.6 kg/m^2 , HbA1c 8.64%), who had a measurement of μ A and RR E/I ratio during a deep breathing test, were submitted to a postural squat-stand test with a continuous noninvasive arterial blood pressure (BP) monitoring (Finapres®). The mirror changes in heart rate and systolic BP during the squat-stand transition allows the calculation of a so-called BRG (msec.mm Hg^{-1}), by plotting the pulse intervals (RR) against systolic BP values, as classically assessed during a pharmacological test using the infusion of a vasodilator and a vasopressor agent. Pulsatile stress was defined as the product of PP and heart rate, both during the whole test and during the squatting position only. The T1DM cohort was divided in two subgroups according to the median value of RR E/I ratio (>1.25 vs <1.25) or of BRG (>2.20 vs $<2.20 \text{ bpm.mmHg}^{-1}$).

Results: Compared to T1DM patients with high BRG ($n = 82$; $4.51 \pm 2.31 \text{ bpm.mmHg}^{-1}$), patients with low BRG ($n = 85$; $1.17 \pm 0.61 \text{ bpm.mmHg}^{-1}$; $p < 0.00001$) tended to be slightly older (42 vs 38 years, NS), to have a slightly longer duration of diabetes (21 vs 18 years; NS), and to have lower RR E/I ratio (1.25 vs 1.31; NS), but had similar recent HbA1c levels (8.64 vs 8.64 %). However, T1DM patients with low BRG had an increased pulsatile stress index (5190 vs $4521 \text{ mmHg.min}^{-1}$; $p = 0.0019$), especially in squatting position (5408 vs $4396 \text{ mmHg.min}^{-1}$; $p < 0.0001$). Similarly, μ A was higher in T1DM patients with low BRG, being expressed by the mean level (59 ± 133 vs $10 \pm 16 \text{ mg/l}$; $p = 0.0019$) or by its logarithm to adjust for a non Gaussian distribution (1.14 ± 0.67 vs 0.76 ± 0.42 ; $p = 0.0001$). There was an inverse correlation between BRG and log μ A ($r = -0.28$; $p = 0.0006$), but not between RR E/I ratio and log μ A ($r = 0.09$; $p = 0.12$). Altogether, 26.9 % of T1DM patients with low BRG had abnormal μ A ($\geq 30 \text{ mg/l}$) versus only 5.3 % of patients with high BRG ($p < 0.001$). Similarly, the correlation between BRG and pulsatile stress ($r = -0.28$; $p = 0.0003$) was stronger than that between RR E/I ratio and pulsatile stress ($r = -0.19$; $p = 0.0153$).

Conclusion: The calculation of BRG during a squat-stand test in subjects with T1DM allows to better detect patients with increased pulsatile stress and even more strongly patients with μ A than the classical RR E/I ratio CAN index. Decreased BRG may be used to detect T1DM patients at high risk of cardiorenal complications.

²Laboratory of Nuclear Medicine, ³Diabetes Division, 1st Propedeutic Department of Internal Medicine, "AHEPA" Hospital of Thessaloniki, Medical School, Aristotle University of Thessaloniki, Greece.

Background and aims: This study investigates if there is an association between glomerular filtration rate (GFR) measurement, as index of renal function, and autonomic function assessment in patients with type 1 diabetes mellitus (T1DM).

Materials and methods: Forty-six patients (28 male, 18 female), aged 36 ± 10 years (range 19–62), with a duration of T1DM 19 ± 6 years (range 7–31), without known diabetic complications and receiving only insulin were enrolled prospectively. Participants were evaluated clinically for autonomic dysfunction with the mean circular resultant (MCR), the Valsalva maneuver (Vals), postural index (PI) and orthostatic hypotension (OH) assessment. The number of abnormal clinical tests was also considered. Within one month patients underwent glomerular filtration rate measurement with ⁵¹Cr-EDTA (expressed in ml/min/1.73m^2) and cardiac ¹²³I metaiodobenzylguanidine (MIBG) imaging [with the ratio of the heart to upper mediastinum count density (H/M) at 4 hours post-injection calculated].

Results: The values of examined variables were as follows [mean \pm 1SD (range)]: GFR 98 ± 17 (61–137), MCR 40 ± 29 (5–108), Vals 1.55 ± 0.30 (1.11–2.29), PI 1.33 ± 0.17 (1.03–1.81), OH 5 ± 9 (0–30) and H/M 1.65 ± 0.20 (1.30–2.34). GFR correlated significantly with age ($r = -0.377$, $p = 0.011$), the duration of diabetes ($r = -0.514$, $p = 0.000$), Vals ($r = 0.377$, $p = 0.010$), OH ($r = -0.448$, $p = 0.002$) and the number of abnormal clinical tests ($r = -0.366$, $p = 0.012$). MCR, PI and the H/M showed no significant correlation with GFR. There was also no significant difference in GFR between male and female patients. In multiple backward regression analysis (in which variables were entered if they were significant in univariate analysis) only the duration of the disease was found to be an independent predictor of GFR.

Conclusion: In T1DM patients GFR is associated with clinically evaluated autonomic function (which predominantly address the parasympathetic system) but not with cardiac MIBG measurements (which reflect sympathetic dysfunction). However, once the duration of T1DM is taken into account it is likely that this association is no more significant.

Exploring prevalence and risk factors for sexual dysfunction in Dutch men and women with type 2 diabetes

M.M.I. van Splunter¹, L.M.C. Welschen¹, J.M. Dekker², F.J. Snoek³, P. Enzlin^{4,5}, G. Nijpels¹;

¹General practice, EMGO+ Institute, ²Epidemiology and biostatistics, EMGO+ Institute, ³Medical Psychology, EMGO+ Institute, Amsterdam, Netherlands, ⁴Institute for Family and Sexuality Studies, Katholieke Universiteit Leuven, ⁵Context - Centre for Marital, Family and Sex therapy, UPC KU Leuven, Belgium.

Background and aims: Diabetes is known to have a negative impact on sexual function in men. Sexual function in women with diabetes, however, has received much less attention and if addressed most studies have exclusively been conducted in women with type 1 diabetes. It has been suggested that in men with diabetes, sexual dysfunction is linked to somatic factors, whereas in women with diabetes psychological factors are more dominant. The aim of this study is to determine the prevalence of sexual dysfunction and study the risk factors of sexual dysfunction in men and women with type 2 diabetes.

Material and methods: A cross-sectional survey study was conducted in patients with type 2 diabetes, aged 40 to 75 years. In total 700 questionnaires were distributed to type 2 diabetes patients of four different diabetes centres in The Netherlands. The Female Sexual Function Index (FSFI) and the International Index of Erectile Function (IIEF) were used to evaluate sexual function. The CES-D was used to evaluate depressive symptoms. Complications were assessed based on self-report. Prevalence of sexual dysfunction was evaluated separately for men and women with type 2 diabetes. Logistic regression analyses were performed to determine which risk factors were associated with sexual dysfunction. Additional subgroup analysis was performed, all adjusted for age.

Results: In total 205 questionnaires were returned (response rate 29%). Mean age of the patients was 62.7 ± 8.1 years, 57.1% was male. Based on pre-defined criterion scores, 68.5% of men and 70.0% of women reported sexual dysfunction. Logistic regression analyses revealed three variables which were associated with sexual dysfunction in men and women with type 2 diabetes: higher age, a depression score ≥ 16 and ≥ 1 diabetes related complications (see Table 1). Depression showed the strongest association with sexual dysfunction and this association remained statistically significant when adjusted for age and diabetes related complications. The association between depression and sexual dysfunction was even stronger in men (OR= 9.67) than women (OR= 6.87) after correction.

Conclusion: Sexual dysfunction is highly prevalent in men and women with type 2 diabetes. Age, depression and diabetes related complications are associated with sexual dysfunctions in women as well as in men with type 2 diabetes. Men with depression had an almost 10-fold higher risk for sexual dysfunction and women a 7-fold higher risk than patients without depression. However it remains unclear whether depression causes sexual dysfunction or sexual dysfunction causes depression.

Table 1. Risk factors for sexual dysfunction in men and women with type 2 diabetes

	Women	Men
	Risk of sexual dysfunction	Risk of sexual dysfunction
<i>Model 1 (Univariate tests)</i>		
Age (10 year period)§	2.74 (1.21 - 6.21)**	2.00 (1.19 - 3.38)**
Depression (CES-D score ≥ 16)†	10.89 (1.27 - 93.07)**	4.51 (1.25 - 16.30)**
Complications‡	5.57 (1.48 - 21.02)**	2.52 (1.01 - 6.24)**
<i>Model 2</i>		
Depression corrected for age	7.43 (0.83 - 66.51)*	6.87 (1.77 - 26.63)**
<i>Model 3</i>		
Depression corrected for age and complications	6.87 (0.73 - 64.41)*	9.67 (1.80 - 51.86)**

Data are Odds ratio's (95% CI); CES-D score range 0 - 60; Sexual dysfunction is measured on the Female Sexual Function Index for women and the International Index of Erectile Function for men;

§ Age is divided in 10-year periods, reference is a 10 year younger person; † Reference category is no depression; ‡ Reference category is no complications; ** $P \leq 0.05$; * $P \leq 0.10$

Cardiovascular, neurological and psychological correlates of sexual dysfunction in diabetic women

D. Cortelazzi¹, C. Mauri¹, A. Marconi², M. Guazzi³, M. Cristina¹, B. Zecchini¹, C. Cattalini⁴, A. Innocenti⁴, G. Bosco⁴, A. Veronelli¹, A.E. Pontiroli¹;

¹Cattedra di Medicina Interna, ²Cattedra di Ostetricia e Ginecologia,

³Cattedra di Cardiologia, ⁴Cattedra di Neurologia, Università Degli Studi di Milano, Italy

Objective: Female Sexual Dysfunction (FSD) has been described in diabetic women, but discrepancies exist between different reports. The aim of this study was to assess the prevalence of sexual dysfunction in women with diabetes mellitus, and to evaluate the metabolic, neurological, cardiovascular, and psychological correlates.

Methods: We studied 100 pre-menopausal women, in stable sex relationship, during follicular phase: 40 with diabetes mellitus (12 T1DM and 28 T2DM, without chronic complications) and 60 age-matched healthy women as controls. Sexual function, depression, and somatic neuropathy were assessed by Female Sexual Function Index questionnaire (FSFI), Beck Depression Inventory (BDI) and Diabetic Somatic Neuropathy Score (DSN), respectively. All women were evaluated for intima-media-thickness (IMT), endothelial vascular function (flow mediated dilatation (FMD), ECG (heart rate and Qtc, indexes of sympathetic activity), echocardiogram, and electromyography (amplitude and conduction of peroneal, posterior tibial, and sural nerves). Fasting blood samples were taken to measure glucose, insulin, fibrinogen, cholesterol (total, HDL-, LDL-), triglycerides, HbA1c, HS-PCR, PRL, testosterone and estradiol. Finally, we evaluated physical activity and smoking habits, parity, weight, BMI and waist circumference (WC).

Results: Score for lubrication and orgasm domains was statistically lower in diabetic women than in control group ($P < 0.05$), as well as nerve conduction and amplitude ($p < 0.05$, $p < 0.001$); diabetic women showed significantly higher BDI and SDN Score ($p < 0.01$, $p < 0.04$, respectively). In all women considered together, FSFI score was directly correlated with echocardiographic

Doppler E waves ($r = 0.24$), physical activity ($r = 0.24$) and with peroneal nerve amplitude ($r = 0.21$), and inversely with parity ($r = 0.298$), age ($r = 0.23$), BDI ($r = 0.43$), SDN ($r = 0.35$), IMT ($r = 0.31$), testosterone ($r = 0.2$), HbA1c ($r = 0.23$), ($P < 0.05$ to $P < 0.01$).

Conclusions: The findings of this study indicate that diabetes, even in the absence of complications, significantly affects sexual function in women. Although depression is the major predictor of FSD, decreased FSFI is associated with sub-clinical vascular and neurological impairment.

1153

Treatment of erectile dysfunction in men with diabetes: results of a phase 3, multicenter, randomised, controlled trial of avanafil

I. Goldstein¹, L.H. Belkoff², C.H. Bowden³, K. DiDonato³, B. Trask³, C.A. Peterson³, W.W. Day³;

¹San Diego Sexual Medicine At Alvarado Hospital, San Diego, ²Philadelphia College of Osteopathic Medicine, Bala Cynwyd, ³VIVUS, Inc., Mountain View, USA.

Background and aims: Erectile dysfunction (ED) is present in >50% of men with diabetes, since comorbidities associated with diabetes (eg, neuropathy, impaired circulation) can interfere with normal erectile function (EF). Treatment with phosphodiesterase type 5 (PDE5) inhibitors currently constitutes first-line therapy. Avanafil is an investigational, rapidly absorbed PDE5 inhibitor with high PDE5 specificity. This study prospectively assessed the safety and efficacy of avanafil for the treatment of ED in adult males with type 1 or type 2 diabetes.

Materials and methods: This multicenter, double-blind, study randomized 390 eligible subjects (type 1 [10.5%] or type 2 [89.5%] diabetes; mild-to-severe ED of ≥ 6 months' duration) to placebo, avanafil 100 mg, or avanafil 200 mg for on-demand use for 12 weeks. Sexual function was assessed using patient diaries and the International Index of Erectile Function (IIEF) questionnaire. Coprimary end points included changes in successful vaginal insertion (Sexual Encounter Profile [SEP2]); successful intercourse (SEP3); and the EF domain score of the IIEF (IIEF-EF). There were no restrictions on the timing of food or alcohol intake, and concurrent alpha-blocker use was permitted.

Results: Least-squares (LS) mean change from baseline in the percentage of successful insertions and intercourse (SEP2 and SEP3, respectively) and in the IIEF-EF domain score were significantly improved following administration of both 100-mg and 200-mg doses of avanafil relative to placebo ($P \leq 0.002$ for both comparisons) (Table). The change from baseline in percentage of attempts resulting in successful intercourse was significantly improved with avanafil vs baseline ($P \leq 0.01$) for subjects with either type 1 or type 2 diabetes, all durations of diabetes history (< 2 to ≥ 10 years), and all ED severity subgroups. Additional analyses indicated that successful intercourse could be achieved in some subjects when initiated ≤ 15 minutes from dosing and, in other subjects, > 6 hours following dosing with avanafil. Most subjects attempted intercourse early; $> 60\%$ of sexual attempts were between 15 and 45 minutes after dosing. The most commonly reported adverse events (AEs) in the avanafil treatment groups were headache (7.8%), nasopharyngitis (3.1%), flushing (2.7%), and sinus congestion (1.9%). There were no drug-related serious AEs and no deaths reported during the study.

Conclusion: Avanafil was studied without food or alcohol restrictions and was found to be well tolerated and effective for mild-to-severe ED in men with type 1 or type 2 diabetes. Data also indicates that avanafil was effective as early as 15 minutes and in some subjects beyond 6 hours after dosing. As subjects with diabetes have a high incidence of ED, avanafil may provide an additional therapeutic option to benefit this population.

End of treatment mean and LS mean change from baseline to week 12 in coprimary end points (ITT)

	Placebo (n=127)		Avanafil 100 mg (n=126)		Avanafil 200 mg (n=126)	
	End of Treatment Mean	LS Mean Change from Baseline	End of Treatment Mean	LS Mean Change from Baseline	End of Treatment Mean	LS Mean Change from Baseline
Successful insertion (SEP2)	42.0%	7.5%	54.0%	21.5%*	63.5%	25.9*
Successful intercourse (SEP3)	20.5%	13.6%	34.4%	28.7%*	40.0%	34.0%*
IIEF-EF domain score†	13.2	1.8	15.8	4.5*	17.3	5.4*

* $P \leq 0.002$ vs placebo; †Baseline values for the IIEF-EF domain score were missing for 4 subjects (2 placebo, 1 avanafil 100 mg, and 1 avanafil 200 mg).

The association between Neuropad testing with peripheral neuropathy in diabetes: a meta-analysis

N. Tentolouris, A. Kokkinos, E. Diakoumopoulou, I. Eleftheriadou, K. Alexiadou;

1st Department of Propaedeutic and Internal Medicine, Athens University Medical School, Laiko General Hospital, Greece.

Background and aims: Published data suggest that the results obtained by visual test Neuropad correlate with presence and degree of peripheral neuropathy as well as with foot ulceration in subjects with diabetes. The aim of this meta-analysis was to examine the association between the results obtained by Neuropad testing with diabetic peripheral neuropathy and its performance in the diagnosis of this complication.

Materials and methods: A total of 8 published studies were identified involving 2146 patients (mean age 58.8 ± 11.2 years; mean duration of diabetes 13.1 ± 8.0 years) with type 1 and type 2 diabetes. A cut-off value of Neuropathy Disability Score ≥ 6 was used for the diagnosis of peripheral neuropathy. Neuropad response was evaluated as normal or abnormal according to complete colour change after 10 min of application. Weighted averages were reported as odds ratios (OR) with 95% confidence intervals using a fixed-effects model. Statistical heterogeneity scores were assessed using the Q and I^2 statistic.

Results: An abnormal Neuropad response was associated with increased OR [9.54 (7.10–12.83)] of peripheral neuropathy, with significant heterogeneity across the trials. An abnormal Neuropad response was associated significantly with peripheral neuropathy in all, but one, studies. The performance of Neuropad testing for the diagnosis of peripheral neuropathy was as follows: sensitivity: 0.85; specificity: 0.56, positive predictive value: 0.50, and negative predictive value: 0.86.

Conclusion: An abnormal Neuropad response after 10 min of application is associated with an almost 10-fold increased risk for peripheral neuropathy in subjects with diabetes. In addition, the test has a high sensitivity for the diagnosis of established peripheral neuropathy.

1155

Assessment of sudomotor function as a tool for cardiorespiratory fitness level evaluation: comparison with V02max

J.-H. Calvet¹, A. Raisanen², J. Eklund², P. Brunswick¹, P. Schwarz³;

¹Impeto Medical, Paris, France, ²Aino Active, Helsinki, Finland, ³Mediinishe Fakultät Carl-Gustav Carus, Dresden, Germany.

Background and aims: Physical inactivity is one of the main modifiable risk factors for cardiovascular (CV) and metabolic disorders. VO2max is the best method to assess cardio-respiratory fitness level but it is poorly accepted by the patient. Sudomotor dysfunction may develop early in cardiometabolic diseases. We compared the usual health analysis tests for CV risk evaluation to EZSCAN® a quick and non invasive method developed to assess sudomotor function.

Materials and methods: Cardio-respiratory fitness level was assessed in Finnish workers through a questionnaire, physical examination (BMI, blood pressure, waist, body composition) and VO2max using a maximal test on bicycle ergometer (T0). Based on local measurements of sudomotor function on hands and feet a cardiometabolic risk score was calculated. Sudomotor function was assessed before and after the exercise test to assess reproducibility of the method. In the subgroup of women with poor fitness level a training program was proposed. Cardio fitness level and sudomotor function were assessed after a 12 month follow-up (T12). Results are expressed as median (iqr). Correlation between V02max and EZSCAN® cardiometabolic risk score was performed using Spearman's rank correlation test.

Results: 537 women (age: 51 (13) years, BMI: 25 (6); VO2max: 8.9 (2.4) METs) and 113 men (age: 52 (11) years, BMI: 25 (4); VO2max: 12.2 (3.4) METs) were involved in the study. A difference in BMI, waist and body fat was present in men and women according to EZSCAN® risk score classification (no risk, moderate risk or high risk). For women and men the correlation between sudomotor function score and V02max was $r = -0.57$, $p < 0.0001$ and 0.48 , $p < 0.0001$ respectively. Coefficient of variation for sudomotor function measurements performed before exercise and after exercise was 5 %. In the subgroup of women with poor fitness level ($n = 65$) correlation between sudomotor function score and V02max was -0.58 , $p < 0.0001$ at T0 and -0.62 , $p < 0.0001$ at T12 (see Figure).

Conclusion: Sudomotor dysfunction as assessed by EZSCAN® is correlated to cardio-respiratory fitness levels and suggests that it can be used to assess

CV or metabolic disease risk and to follow individual preventive interventions.

1156

Sudomotor dysfunction and cardiovascular autonomic neuropathy assessed by spectral analysis of heart rate variability in diabetes

P. Brunswick¹, J.-H. Calvet¹, J.-P. Deslypere², C. Yajnik³;

¹Impeto Medical, Paris, France, ²Aesculape, Singapore, ³King Edward Memorial Hospital, Pune, India.

Background and aims: Cardiovascular autonomic neuropathy (CAN) is a common but frequently overlooked complication of diabetes. Sweat glands are innervated by small unmyelinated sympathetic C-fibers that can be damaged very early in the disease course. A consensus statement of the American Diabetes Association has suggested that sudomotor function should be included in diagnostic test for early detection of diabetic neuropathy. SUDOSCAN a new quick, non invasive and quantitative method recently developed to simply assess sweat gland function was compared to spectral analysis of heart rate variability at rest and during exercise known to be valuable and reliable method for investigation of CAN.

Materials and methods: 241 patients with diabetes were involved in this study. The investigation consisted of spectral analysis of heart rate variability at rest (15 min) and during exercise (45 min, stair climbing) with measurement of average standard deviation of all NN intervals over 5 minutes (ASDNN-5min), High Frequency component (HF, linked to parasympathetic nervous system) and Low Frequency domain component (LF, linked to sympathetic nervous system). Sweat function was measured on hands and feet (areas with the highest sweat gland density). Patients placed their hands and feet on large electrodes where a low voltage ($<4V$) was applied during 2 minutes. Results are expressed as median (iqr), comparisons were done using Kruskal-Wallis test or quantile regression (for adjustment).

Results: As diabetic peripheral nerve function is disturbed in a length dependent manner, patients were classified according to the results of their feet sweat function expressed as the feet Electrochemical Sweat Conductance (ESC, μS): feet ESC $> 60\mu S$ no sweat dysfunction, $40-60\mu S$ moderate sweat dysfunction, $< 40\mu S$ high sweat dysfunction. Results of heart rate variability according to sweat dysfunction are displayed in the Table.

Conclusion: SUDOSCAN allowing quick and quantitative assessment of sudomotor function can be used for early screening of cardiovascular autonomic neuropathy in daily clinical practice before performance of more sophisticated, more specific but more time consuming tests.

Demography and heart rate variability data according to feet ESC						
	All (n=241)	Feet ESC > 60 μ S (n=117)	Feet ESC 40–60 μ S (n=63)	Feet ESC < 40 μ S (n=61)	p value Kruskall- Wallis test	p value adjusted on age and diabetes duration

Oxidative stress and diabetic neuropathy

A. Sliwinska¹, M. Mrowicka², M. Kosmalksi¹, J. Kasznicki¹, I. Majsterek², J. Drzewoski¹;

¹Department of Internal Medicine, Diabetology and Clinical Pharmacology, Medical University of Lodz, Zgierz, ²Department of Medical Chemistry and Biochemistry, Medical University of Lodz, Poland.

Background and aims: Diabetic neuropathies (DN) are one of the most common complications of diabetes mellitus affecting ~ 50% of all diabetics. Experimental evidences suggest that hyperglycaemia-induced excessive reactive oxygen species (ROS) production and subsequent damage to proteins, lipids and DNA play a key role in degradation of neurons. The disturbances of antioxidant enzyme defense system (including superoxide dismutase - SOD, catalase - CAT and glutathione peroxidase - GPx) are also thought to contribute to the pathogenesis of DN. The study was designed to evaluate the level of oxidative stress parameters such as total antioxidants status (TAS), concentration of nitric oxide (NO), the level of DNA damage, and activity of antioxidant enzymes in type 2 diabetes mellitus (T2DM) patients with coexisting neuropathy.

Materials and methods: This study included 19 healthy subjects, 16 T2DM patients without and 16 T2DM patients with DN. The concentration of TAS and NO were measured in plasma. The level of DNA damage in lymphocytes of peripheral blood was assessed by the alkaline comet assay. The activity of SOD1, GPx and CAT were measured in erythrocyte hemolysate.

Results: No significant difference was observed between three groups regarding to age. Healthy subject revealed significantly higher NO plasma concentration ($8.9 \pm 1.6 \mu\text{mol/L}$) than T2DM patients with and without DN (7.6 ± 0.9 and 7.7 ± 1.3 , respectively) ($p < 0.05$). In T2DM patients with DN the level of TAS was lower than in patients without DNS and healthy subject (0.96 ± 0.3 vs 1.05 ± 0.21 vs 1.11 ± 0.3 mmol/L). Lymphocytes of T2DM patients with and without neuropathy exerted significantly higher level of endogenous and oxidative DNA damage compared to healthy subjects (Figure). Moreover, DNA of lymphocytes isolated from T2DM patients with and without DN was more susceptible for damage induced by hydrogen peroxide (Figure). The erythrocyte activity of SOD1 [U/gHb/100ml] was significantly lower ($p < 0.05$) in T2DM patients with DN (1895 ± 193) compared to healthy subject (2201 ± 529) and T2DM patients (2005 ± 320). The activity of GPx was markedly reduced ($p < 0.05$) in T2DM patients with DN (45.1 ± 8.8) compared to healthy subject (51.5 ± 9.2) and T2DM patients (50.8 ± 8.9). The CAT activity was lower in both groups of diabetics than in healthy subjects, but differences did not reach a significant statistical power.

Conclusion: We found the higher level of oxidative stress in T2DM people with DN. The higher level of oxidative stress was associated with lower antioxidant enzymes activity, depletion in plasma antioxidant status, reduced level of NO, and significantly higher level of DNA damage. These findings provide further evidence that the development of DN may be associated with inappropriate oxidant/antioxidant balance in people with diabetes mellitus.

The $\epsilon 4$ allele of APOE gene is associated with more severe diabetic peripheral neuropathy in type 2 diabetic patients

C. Monastiriotis¹, K. Karanikola², N. Papanas¹, S. Veletza², G. Trypsianis³, E. Maltezos¹;

¹Outpatient Clinic of Obesity, Diabetes and Metabolism, Second Department of Internal Medicine, ²Laboratory of Medical Biology,

³Department of Medical Statistics, Democritus University of Thrace, Alexandroupolis, Greece.

Background and aims: The $\epsilon 4$ allele of APOE gene is a recognised risk factor for several neuromuscular diseases. However, some studies have cast doubt on this relation in diabetic neuropathy. Therefore, the aim of the present study was to investigate the potential adverse effect of $\epsilon 4$ allele of APOE gene on the severity of peripheral diabetic neuropathy in type 2 diabetic patients

Materials and methods: This study included 234 type 2 diabetic patients (120 men, age [mean \pm SD] 65.35 \pm 8.26 years, diabetes duration 12.08 \pm 8.01 years). Diabetic peripheral neuropathy was diagnosed and graded according to the Neuropathy Disability Score (NDS). Patients were grouped into those exhibiting mild (NDS lower than or equal to 6) and those exhibiting severe (NDS greater than 6) diabetic peripheral neuropathy. They were also genotyped for APOE gene and each NDS group was further divided into two subgroups, i.e. $\epsilon 4$ carriers and $\epsilon 4$ non-carriers. To evaluate the risk of severe diabetic peripheral neuropathy according to $\epsilon 4$ carrier status, logistic regression analysis was performed with adjustment for gender, age, duration of diabetes and HbA1c levels. Finally, the association between severity of neuropathy and the aforementioned patient characteristics was investigated as well.

Results: The relative risk of severe diabetic peripheral neuropathy was more than 5-fold increased in $\epsilon 4$ carriers (Adjusted OR: 5.26; 95% CI: 2.24–12.31; $p=0.0001$). Other significant risk factors were male gender ($p=0.036$), diabetes duration ($p=0.039$), and HbA1c levels ($p=0.020$).

Conclusion: Among type 2 diabetic patients, those carrying the $\epsilon 4$ allele of the APOE gene have a significantly higher risk of severe diabetic peripheral neuropathy.

1159

Evaluating a new device in the assessment of peripheral sensory neuropathy in diabetes: the Vibratip® study

N.J. Bracewell¹, B.E. Scammell², W.J. Jeffcoate³, F.L. Game³;

¹University of Nottingham, ²Division of Orthopaedic and Accident Surgery, University of Nottingham, ³Department of Diabetes and Endocrinology, Nottingham University Hospitals Trust, UK.

Background and aims: To evaluate the sensitivity, specificity, predictive values and likelihood ratios of a new device, Vibratip®, for detecting diabetic peripheral neuropathy (DPN) in routine clinical screening and to assess the intra-rater reliability of the Vibratip.

Materials and methods: The Vibratip was compared with the current reference for loss of protective sensation (Neurothesiometer®), as well as other bedside methods: 10g monofilament, 128Hz tuning fork and Neurotip®. 141 patients with type I or type II diabetes were studied. Sensation at five sites on each foot was assessed with a 10g monofilament, Neurotip and Vibratip and at two sites with a 128Hz tuning fork. A Neurothesiometer result at the hallux pulp $\geq 25V$ in either foot was considered indicative of DPN. Receiver operating characteristic (ROC) curves were produced and sensitivity, specificity, predictive values and likelihood ratios subsequently calculated. Sensation was assessed using the Vibratip twice in 18 patients and intra-rater reliability calculated using Cronbach's alpha.

Results: The sensitivities of the 10g monofilament, Vibratip, Neurotip and 128Hz tuning fork were found to be 84%, 79%, 74% and 69% respectively for the diagnosis of DPN. The negative likelihood ratios were 0.19, 0.25, 0.31 and 0.34, respectively. The ROC curves indicated that ≥ 2 insensate sites from 10 tested across two feet was predictive of a diagnosis of DPN for the 10g monofilament, Neurotip and Vibratip whereas ≥ 1 insensate site was predictive for the 128Hz tuning fork. The 10g monofilament had the best overall performance when compared with the Neurothesiometer, performing statistically significantly better than the 128Hz Tuning Fork and Neurotip ($p=0.0056$ and 0.0022 respectively). The alpha coefficient for Vibratip was 0.88, indicating good reliability.

Conclusion: In the detection of DPN as defined by the use of a Neurothesiometer, the performance of the 10g monofilament and Vibratip were comparable. Supported by: Samples of the Vibratip provided by the manufacturer.

Skin autofluorescence relates to soluble receptor for advanced glycation endproducts in diabetic patients

J. Škrha jr.^{1,2}, J. Šoupal¹, G.E. Loni³, J. Švarcová², M. Kalousová², M. Prázný¹, J. Škrha¹;

¹3rd Department of Medicine, First Faculty of Medicine, ²Institute of Clinical Biochemistry and Laboratory Diagnostics, First Faculty of Medicine, Charles University in Prague and General University Hospital, Czech Republic, ³Department of Internal Medicine, Ayos District Hospital, Yaounde, Cameroon.

Background and aims: Advanced glycation endproducts (AGEs) play important role in the pathogenesis of diabetic complications. Their accumulation in the skin evokes elevation of skin autofluorescence (AF). According to novel findings, soluble receptors for AGEs (sRAGE) can reduce the pro-inflammatory effect of AGEs due to decreased activation of RAGE. The aim of this study was to evaluate skin autofluorescence levels in diabetic patients in respect of their sRAGE levels and other metabolic parameters.

Materials and methods: Skin AF was measured in 121 diabetic patients (62 Type 1 /T1DM/, 58 Type 2 /T2DM/; aged 54 \pm 16 yrs) and 26 healthy controls (aged 45 \pm 12 yrs) on forearm 3 times consecutively by AGE-Reader (Diagnoptics BV, Groningen, Netherlands). Results were expressed as arbitrary units (AU) and compared with age, diabetes duration, sRAGE concentration determined by ELISA kit, glycated hemoglobin HbA1c (expressed in IFCC units) and fructosamine. Albuminuria was expressed as albumine-creatinine ratio (ACR).

Results: Skin AF was significantly higher in both T1DM and T2DM as compared to healthy controls (2.35 \pm 0.56 AU, 2.62 \pm 0.69 AU vs 2.04 \pm 0.47 AU, ANOVA $p=0.0003$). Mean HbA1c was similar in both types of diabetic patients (7.5 \pm 1.8 % vs 7.0 \pm 2.1 %, NS). Significant relationship was found between AF and age (T1DM: $r=0.6$, $p<0.0001$, T2DM: $r=0.32$, $p<0.01$ and controls: $r=0.62$, $p<0.001$), and between AF and diabetes duration ($r=0.30$, $p<0.02$; $r=0.36$, $p<0.006$). However, no relationship was observed between AF and HbA1c or fructosamine in both T1DM and T2DM. Significant correlation was found between AF and sRAGE in all diabetic patients ($r=0.45$, $p<0.0001$), both in T1DM ($r=0.31$, $p<0.03$) and in T2DM ($r=0.63$, $p<0.0001$). Interestingly, patients with normal albuminuria (ACR<2.5 g/mol creatinine) had significantly lower AF in comparison to patients with positive (micro)albuminuria (T1DM: 2.25 \pm 0.52 vs 2.75 \pm 0.57 AU, $p=0.0003$; T2DM: 2.45 \pm 0.61 vs 3.01 \pm 0.84 AU, $p=0.0003$). Significant positive relationship was found between AF and (micro) albuminuria in both T1DM and T2DM ($r=0.36$, $p<0.005$ and $r=0.42$, $p<0.003$).

Conclusion: This is the first study describing relationship of the skin autofluorescence and serum sRAGE concentrations in Type 1 and Type 2 diabetic patients. In addition, higher levels of skin AF and sRAGE are related to more advanced vascular changes evaluated by albuminuria, but without any effect of actual diabetes control. It may be speculated that development of diabetic angiopathy is associated with markers of AGEs formation and in parallel with generation of protective mechanisms as free sRAGE molecules. Their role and interplay in the whole process of chronic diabetic complications will be confirmed in the follow-up study.

Diabetic foot ulcer risk stratification systems: Which one to choose?

A validation study

M. Monteiro-Soares, R. Guimarães, A. Távora, E. Lemos, I. Duarte, J. Sobral, J. Campos-Lemos, D. Brandão, M. Madureira, M. Ribeiro, M.J. Oliveira; Endocrinology, Diabetes and Metabolism, CHVNG / Espinho EPE, Vila Nova de Gaia, Portugal.

Background and aims: Diabetic foot ulcer (DFU) risk stratification systems are a crucial tool for diabetic foot care, screening, resource allocation and complications' prevention. There are various systems with different characteristics and a recent systematic review has shown that little has been done for their validation and comparison. In fact, some of them were never externally validated nor their prognostic accuracy reported. Therefore, choosing which one to apply in our setting may not be straightforward. Thus, this study aims to validate and compare all the available systems [the University of Texas (UT), American Diabetes Association (ADA), International Working Group on the Diabetic Foot (IWGDF), Scottish Intercollegiate Grouping Network (SIGN) and Boyko and colleagues] for DFU occurrence prediction at 1 year (the lowest risk group recommended reevaluation).

Materials and methods: A retrospective cohort study was conducted on all patients with diabetes but without active DFU attending the CHVNG/Es-pinho EPE Diabetic Foot Clinic, from March 2006 to March 2011 ($n = 270$). Characterization variables (age, gender, diabetes' duration, type and treatment) and all those included in the stratification systems were assessed and registered at baseline [HbA1C, neuropathy and peripheral vascular disease, foot deformity, callus, visual and physical impairment, onychomycosis, tinea pedis, previous DFU and lower extremity amputation (LEA)]. Later, variables were collected from the patients' clinical files from mid to end of March 2011. All systems were applied at the data collection moment. Participants were followed for 1 year or until DFU occurred, i. e., a full-thickness skin defect distal to the malleoli requiring more than 14 days to heal. Variables' distribution was compared between the groups of patients with and without ulcers over the follow-up course, using the appropriate statistical tests (according to the variables' type and normality of distribution). Significance was defined as $p < 0.05$.

Results: Type 2 diabetes was present in 99.6% of patients, 44.2% were men and (at baseline) the median age was 66 years and diabetes duration 16 years. Median follow-up was 12 months (range 1–12) during which 29 participants (10.7%) developed a DFU. Variables associated with DFU occurrence at 1 year were age, HbA1C, Semmes-Weinstein monofilament and/or tuning fork sensitivity alteration, number of pulses present, previous DFU or LEA. For all the systems there were more ulcerations as the risk group increased (χ^2 for association and trend $p < 0.001$). The UT system presented an area under the receiver operating curve (AUC) of 0.70 [95% confidence interval (CI) 0.58–0.81], the ADA system of 0.82 (95% CI 0.77–0.88), the IWGDF system of 0.84 (95% CI 0.77–0.91), the SIGN system of 0.75 (95% CI 0.68–0.82) and the Boyko and colleagues system of 0.82 (95% CI 0.74–0.90).

Conclusion: There are several risk stratification systems that can be used in clinical practice to detect those at higher risk of DFU occurrence and they seem to be equally accurate. Although the selection of which system to apply is still unclear, this study shows that all of these systems present a high accuracy and therefore are a valuable tool. Nevertheless, further validation studies should be performed in larger samples and in different settings. There is also a great need to assess the reliability of the systems and their components.

1162

Endothelial dysfunction in diabetic subjects with neuropathic foot ulceration

M.R. El-Nahas¹, H. Gawish¹, A. Abd Al-Baky², T. Amer³;

¹Endocrinology and Diabetes Unit, Internal Medicine Department, ²Clinical Pathology Department, ³Radiology Department, Mansoura University, Egypt.

Background and aims: Diabetic patients with foot ulceration have increased risk of cardiovascular disease (CVD) that may seem logical for patients with ischemic ulcers. However, increased CVD had also been reported in patients with neuropathic foot ulceration (NFU) without clear explanation. Current evidence suggests that endothelial dysfunction contributes to the formation, progression, and complications of atherosclerosis. The aim of this study was to evaluate endothelial dysfunction as a possible element for excess CVD burden in diabetic patients with NFU.

Materials and methods: The study included forty diabetic subjects with NFU (The Neuropathic Group) and twenty diabetic subjects without peripheral nerve dysfunction (The Diabetic Group). The two groups were carefully selected to be matched for age (54.3 ± 7.6 vs. 56.3 ± 7.5 yrs, $P = 0.337$), sex (M/F: 21/19 vs. 12/8, $P = 0.784$), BMI (39.5 ± 7.1 vs. 36.8 ± 5.2 , $P = 0.103$), systolic and diastolic blood pressure (147.5 ± 21.9 vs. 140.8 ± 18.2 , $P = 0.213$ and 90 ± 9.9 vs. 88.3 ± 9.2 , $P = 0.503$ mmHg respectively). All subjects were treated with insulin. Subjects with renal impairment, peripheral arterial disease, smoking or using oral hypoglycemic or lipid lowering drugs were excluded. Endothelial function was evaluated by flow-mediated dilation (FMD) in the brachial artery after reactive hyperemia using high-resolution ultrasound (Toshiba Powervision 6000 with a 7.5 MHz linear array transducer). Carotid intimal medial thickness (CIMT) and FMD were evaluated by a single radiologist blinded to the study variables.

Results: FMD in the brachial artery was much reduced in the neuropathic group in comparison with the diabetic group (4.5 ± 4.4 vs. 16.1 ± 8.5 %, $P = 0.001$). Both groups were comparable in CIMT (1.2 ± 0.4 vs. 1.3 ± 0.4 mm, $P = 0.318$), A1c% (8.6 ± 0.7 vs. 8.8 ± 0.8 , $p = 0.413$), total cholesterol (205.6 ± 12.7 vs. 203.3 ± 16.5 mg/dl, $P = 0.575$) and triglycerides (201.5 ± 30.8 vs. 211.5 ± 36.3 mg/dl, $P = 0.299$). However, diabetes duration and waist circumference were significantly increased in the neuropathic group (17.3 ± 6.9 vs. 8 ± 5.8 yrs, $p =$

0.000 and 125.6 ± 9.7 vs. 118.3 ± 13.1 cm, $P = 0.022$ respectively). FMD correlated inversely with CIMT ($r = -0.319$, $P = 0.045$), age ($r = -0.34$, $P = 0.032$) and ulcer area ($r = -0.453$, $P = 0.005$) but not with duration of diabetes, BMI, waist circumference, ulcer duration, systolic or diastolic blood pressure. FMD was much reduced in men in comparison to women (2.9 ± 4.7 vs. 6.1 ± 3.4 %, $P = 0.023$).

Conclusion: The results of this study demonstrate more remarkable endothelial dysfunction in diabetic subjects with NFU in comparison to a matched group without peripheral nerve dysfunction. Endothelial dysfunction was greater in men and FMD was inversely and strongly related to CIMT, age of the patients and ulcer area. We suggest that attention should be paid to endothelial dysfunction in diabetic subjects with NFU in order to save not only limbs but also lives.

1163

Are certain psychological parameters independent risk factors for outcomes of diabetic foot therapy?

V. Fejfarová¹, A. Jirkovská¹, E. Dragomirecka², R. Bem¹, M. Dubský¹, V. Woskova¹, V. Lanska¹;

¹Diabetes Center, Institute for Clinical and Experimental Medicine,

²Psychiatric Center, Prague, Czech Republic.

Background and aims: The healing of the diabetic foot (DF) could depend not only on complex therapy served by health providers but also on patient compliance that is relying on certain psychological parameters of treated patients. The aim of our study was to assess possible associations of selected psychological parameters with the outcomes of DF therapy.

Materials and methods: 59 patients with DF (mean age 58.9 ± 9.5 years, diabetes duration 20.1 ± 11.4 years, HbA1c according to IFCC $6.3 \pm 2\%$) whose were consecutively treated in foot clinic from 1/2010 to 3/2010 were included into our study. In these patients certain psychological parameters were evaluated by following psychological tests - degree of pain by Visual Analog Scale, degree of depression by Geriatric depression scale, QoL by 4 domains (Physical, Psychological domains, Social Relationships and Environment) based on WHOQoL-Bref test, consequences of stress action by Social Readaptation Scale and discrimination of stress factors by Stress Scale. The follow up of one year of the outcomes of DF therapy was performed after the inclusion into our study. The primary endpoints were defined by Global Impression-Improvement Score as the improvement of DF (1–3; including healing and improvement of local findings) and the worsening of DF (5–7; including progression of local findings, lower limb amputations and death). During the observed period 22/59 study patients healed (37.2%), 15/59 underwent amputations (25.4%) and only 1/59 death was recorded (1.7%). The possible associations of psychological parameters with secondary end-points (number of hospitalizations, new ulceration development) were also assessed.

Results: Neither QoL (Physical domain - 12.2 ± 2.8 vs. 12.3 ± 3.1 , Psychological domain - 14.4 ± 2.4 vs. 14 ± 3.1 , domain of Social Relationships 14.7 ± 2.8 vs. 14 ± 3.3 and of Environment 13.8 ± 2.1 vs. 13.7 ± 2.5 ; NS) nor other psychological parameters including the degree of depression (12.4 ± 3.6 in patients with the improvement of DF vs. 12.9 ± 2.6 in patients with the worsening of DF; NS) were significantly associated with the primary end-points of DF therapy. Similarly secondary end-points were not significantly influenced by selected psychological parameters.

Conclusion: Selected psychological parameters had no predicting values for 1-year follow up therapy outcomes in patients with the DF. Possibly other redefinition (healed x unhealed DF) of primary end-points will be useful for statistical analyzing due to possible overlapping of patients psychological characteristics related to outcomes of DF therapy.

Risk predictors of lower-limb amputation in patients with type 2 diabetes mellitus in the fenofibrate intervention and event lowering in diabetes study

J.K. Rajamani, L. Li, J.D. Best, M. Voysey, R. Ting, M.C. d'Emden, M. Laakso, J.R. Baker, A.C. Keech;

c/o NHMRC Clinical Trials Centre, The University of Sydney, Camperdown, Australia.

Background and aims: Lower limb amputations associated with type 2 diabetes cause major disability and portend a high mortality over the next few

years. The aim of this analysis was to identify important risk predictors for future lower limb amputation among a large cohort of 9795 patients with type 2 diabetes mellitus in the Fenofibrate and Event Lowering in Diabetes (FIELD) study.

Materials and methods: Patients were randomised to receive co-micronised fenofibrate 200 mg/day or matching placebo over 5 years, and amputation events (a prespecified tertiary endpoint) were documented at 6-monthly intervals. Time to amputation was evaluated in multivariable proportional-hazards regression analysis using exhaustive-search methods to develop predictive models.

Results: The main predictors of the first on-study amputation were a history of previous diabetic skin ulcer or non-traumatic amputation (hazard ratio [HR] 5.6), neuropathy (HR 3.0), peripheral vascular disease (HR 2.6), age over 65 years (HR 2.04) and height (HR 1.5 per 10 cm taller) (all $P < 0.001$). Other significant predictors included smoking, albuminuria, HbA1c, retinopathy and PTCA. Increasing risk of cardiovascular disease events and death was associated with increasing amputation risk (trend $P < 0.0001$).

Conclusions: Classical markers of macrovascular and microvascular risk predicted amputations. We also identified height as a major predictor of diabetic amputations, independent of the presence of neuropathy, confirming a previous report from an observational study. These findings could enable more aggressive targeting of modifiable risk factors among patients at high risk of amputations and subsequent cardiovascular events who would benefit most from aggressive therapeutic intervention.

Charcot neuroarthropathy is a risk factor of coronary stenosis independent of calcium score

D. Pitocco, R. Marano, F. Zaccardi, T. Musella, G. Verrillo, F. Martini, G. Scavone, M. Galli, S. Caputo, L. Bonomo, G. Ghirlanda; Catholic University, Rome, Italy.

Background and aims: Type 2 diabetic subjects have an increased cardiovascular mortality. This elevated risk is linked to an accelerated vascular atherosclerosis, in particular coronary atherosclerosis. Coronary artery calcium (CAC) is an integral part of atherosclerotic coronary heart disease and there are several studies supporting the role of CAC score for prediction of myocardial infarction and cardiovascular mortality. The aim of our small cross-sectional study was to explore the differences in coronary calcium score (CCS, a marker of CAC) in four different populations.

Materials and methods: 10 health subjects, 10 uncomplicated type 2 diabetic patients, 10 type 2 diabetic patients with autonomic neuropathy and 10 type 2 diabetic subjects with Charcot Osteoarthropathy. The diagnosis of autonomic neuropathy was made with cardiovascular tests while Charcot foot was defined according to clinical signs and symptoms. CCS and CT Coronary Angiography were both performed by a 64-row multidetector CT scanner with ECG-gating.

Results: The three diabetic groups did not present significant differences about the variables known to influence coronary atherosclerosis (age, sex, disease duration, lipids, HbA1c, Waist-to-Hip ratio). Comparing diabetics with health controls, only HbA1c was significantly different ($p < 0.001$). All Charcot and diabetic patients with autonomic neuropathy had a cardiovascular autonomic score > 5 compared to controls and uncomplicated diabetics (all < 2 ; $p < 0.001$). With regard to total CCS, it was significantly higher in diabetic patients compared to controls (179 AS [112–862] vs 3.5 AS [3–4], respectively; $p = 0.009$), without differences among the three diabetic groups. Notwithstanding this, the rate of Charcot patients with coronary stenosis $> 50\%$ (clinically significant stenosis) was higher compared to no-Charcot patients (79 vs 52%; $p = 0.038$).

Conclusion: In conclusion, our study supports previous findings about CCS of diabetic subjects and underlines as Charcot Osteoarthropathy could be considered a prognostic marker of a more severe coronary atherosclerotic lesions. Further, larger and hard-points studies are necessary to confirm these data.

PS 106 Wound healing: experimental

1166

Insulin signalling regulates keratin-intermediate filaments structure and function

A. Blau Ben Yaakov, E. Dror, G. Weingarten, E. Wertheimer; Dept. of Pathology, Sackler Faculty of Medicine, Tel-Aviv University, Israel.

Background and aims: In recent years, new roles for insulin have emerged, including regulation of cellular proliferation, differentiation, and apoptosis. However, it has not yet been determined whether these newly recognized insulin regulatory functions have any clinical significance. Previously, we demonstrated that insulin is essential for skin proliferation and differentiation. Furthermore, we have found that insulin receptor (IR) deficient mice have impaired wound healing. This skin pathology was associated with abnormal structure of epidermal keratin 1 (K1) filaments. K1 is a member of the intermediate filaments family. These cytoskeletal proteins give the cell its strength, shape and motility. Thus, insulin-induced changes in the structure and assembly of keratins might lead to impaired cellular function. To further investigate insulin regulation of K1 structure and assembly, we further studied skin cells isolated from IR and IRS1 knockout mice (IRKO and IRS1KO respectively). In addition, we have established a human based cell model in which IR or IRS1 were inactivated.

Materials and methods: Primary cultures of keratinocytes are isolated from newborn IRKO, IRS1KO and control mice as previously set in our lab. IR or IRS1 silencing in human skin cells was achieved by expression of IR or IRS1 targeted shRNA in human keratinocyte HaCaT cells (IRKD and IRS1KD respectively). K1 assembly, structure and function are evaluated by Western Blot analysis, indirect immunofluorescence and confocal microscopy.

Results: Lack of IR resulted in a marked decrease in insoluble K1 filament level, indicating that K1 assembly is impaired in the IRKO cells. This decrease was associated with abnormal structure of K1 filaments, as visualized by indirect immunofluorescence (fig. 1). Interestingly, we have found that these changes were associated with changes in K1 serine phosphorylation. While in control cells insulin increased K1 phosphorylation, there was no K1 phosphorylation in the IRKO cells. Lack of IRS1 resulted in further deterioration in K1 expression, as IRS1KO murine cells show a decrease in both soluble and insoluble K1 expression. Thus, lack of IRS1 affects both the assembly as well as the expression of K1. These results were further corroborated in the human IRKD and IRS1KD cells. Human IRKD cells show a decrease in insoluble K1, whereas IRS1KD cells show a decrease in insoluble and soluble K1, as was found in the murine cells. Interestingly, both IRKD and IRS1KD cells had significantly lower proliferation rates compared to control keratinocytes. In addition, IRKD cells demonstrated decreased adhesion to ECM proteins.

Conclusion: Our results demonstrate for the first time that insulin regulates the structure, phosphorylation and function of keratin intermediate filaments. These findings suggest that insulin signaling is essential for normal skin development, and that impaired insulin signaling, as occurs in diabetes, directly contributes to the pathogenesis of impaired wound healing in diabetes.

Figure 1: Indirect immunofluorescence of keratin 1 filaments. Primary IRKO and WT murine keratinocytes were grown on coverslips. K1 protein was visualized by indirect immunofluorescence using a rabbit anti-mouse keratin 1 antibody as the primary antibody. The secondary antibody was Cy3-labeled goat anti-rabbit IgG (red). The nuclei of the cells were visualized by DAPI staining. Fluorescence signals were analyzed by confocal microscopy ($\times 63$).

1167

Impaired mast cell function affects wound healing in diabetesA. Tellechea^{1,2}, J.M. Zabolotny¹, L. Pradhan¹, E. Leal², A. Kafanas¹, S. Kuchibhotla¹, E. Carvalho^{2,1}, A. Veves¹;¹Harvard Medical School, Beth Israel Deaconess Medical Center, Boston, USA, ²Center for Neurosciences and Cell Biology, University of Coimbra, Portugal.

Background and aims: Recent studies suggest that neuropeptides and mast cells participate in wound healing but the mechanisms of their action are not clear. Our hypothesis is that skin mast cells are dysfunctional in diabetes due to neuropeptide deficiency, contributing to impaired wound healing.

Materials and methods: We assessed wound healing in both streptozotocin-induced diabetic (STZ-DM) and non-diabetic (non-DM) mast cell deficient mice (KitW/KitW-v) and their wild type (WT) littermates. Two 6-mm excision wounds per mouse were created on the dorsum of the anesthetized mice, wound healing was followed for ten days and wounds were harvested afterwards. In some animals, one wound was treated with Substance P (SP) and one with placebo. Skin O₂ hemoglobin saturation was determined prior to wounding (day 0) and at day 10 using hyperspectral imaging. To confirm the presence/absence of mast cells and to evaluate gene expression of growth factor and cytokines at the skin level, toluidine blue staining and q-RT-PCR were performed.

Results: Wound healing was delayed in mast cell deficient mice compared to WT mice. This impairment was evident at days 5 to 10 in the non-DM group and at days 8 to 10 in the STZ-DM group ($p < 0.05$). Furthermore, hemoglobin saturation was significantly lower in both non-DM and STZ-DM mast cell deficient mice when compared to WT non-DM and STZ-DM mice, respectively, at day 10 post-wounding ($p < 0.01$). Topical treatment of the wounds with SP accelerated wound closure in both non-DM and STZ-DM WT mice ($p < 0.05$), but had no effect in the KitW/KitW-v mice. As expected, the KitW/KitW-v mice did not have any mast cells at the skin level. WT STZ-DM mice had a lower mast cell count when compared to the non-DM mice but showed higher mast cell degranulation levels ($p < 0.05$). At day 10 post-wounding, gene expression of FGF, EGF, VEGF and MPO was decreased while gene expression of KC, IL-6, MMP-9 and SP was increased in the skin of KitW/KitW-v mice when compared to WT ($p < 0.05$).

Conclusion: Mast cell deficiency severely impairs wound healing in both DM and non-DM settings and leads to skin hypoxia and aberrant expression of growth factor and cytokines. STZ-induced diabetes affects skin mast cell abundance and function. SP exerts its beneficial effect on wound healing, at least partly, through mast cell function.

Protein tyrosine phosphatase 1B (PTP1B) deficiency promotes wound healingJ.M. Zabolotny¹, A. Tellechea^{1,2}, E. Leal², I. Kontoes², S. Kuchibhotla², L. Pradhan², E. Carvalho³, A. Veves²;¹Division of Endocrinology, Diabetes, and Metabolism, Beth Israel Deaconess Medical Center, ²Surgery, Beth Israel Deaconess Medical Center, Boston, USA, ³Center for Neurosciences and Cell Biology, University of Coimbra, Portugal.

Background and aims: The major complication of diabetes leading to hospitalization is chronic diabetic foot ulceration. Growth factors play a key role in wound healing, and wound site growth factor deficiency is associated with impaired healing of diabetic foot ulcers. PTP1B negatively regulates a network of growth factor and cytokine signaling pathways that promote wound healing, including vascular endothelial growth factor (VEGF), platelet derived growth factor (PDGF), epidermal growth factor (EGF), and leptin via dephosphorylation of their respective receptors or associated kinases. In mice, PTP1B expression is increased in a variety of tissues by obesity- or diabetes-associated inflammation and is elevated in response to tumor necrosis factor alpha (TNF α) treatment. The aim of the current studies was to determine whether PTP1B affects skin wound healing progress in healthy mice as well as in the context of diabetes.

Materials and methods: Wound closure kinetics of full thickness excisional skin wounds in PTP1B-deficient mice were compared to those of wildtype control mice. The effect of PTP1B deficiency on wound healing was also compared that of topically applied leptin, which is known to promote wound

healing. Medical hyperspectral imaging (MHSI), an advanced form of spectroscopy that provides a 2D map of tissue oxygenation, was used to measure tissue oxyhemoglobin and deoxyhemoglobin of the periwound area pre- and post-wounding to determine oxygen saturation of hemoglobin during the healing process. Mice were also made diabetic by streptozotocin treatment and wound closure kinetics examined.

Results: PTP1B deficiency in mice enhanced wound closure by ~25% at day 3 and by ~50% at day 10 post wounding compared to wildtype control mice ($p \leq 0.05$ for both measurements). Importantly, PTP1B deficiency also enhanced the ability of topical leptin to promote wound healing compared to that observed in wildtype mice receiving topical leptin. Prior to wounding, oxygen saturation of hemoglobin measured by MHSI in skin of wildtype and PTP1B-deficient mice was similar. In contrast, periwound hemoglobin oxygen saturation was enhanced by ~10% at day 3 and by ~20% at day 10 post wounding in PTP1B-deficient mice compared to wildtype, consistent with experimental and clinical findings linking tissue oxygen saturation with increased rates of wound healing. The effects of PTP1B deficiency on wound healing were similar in diabetic mice. Wound healing was enhanced by ~50% in diabetic PTP1B-deficient mice compared to diabetic wildtype controls by day 10 post wounding ($p \leq 0.05$).

Conclusion: These data show that augmenting signal transduction via PTP1B deficiency enhances skin wound healing in mice in both the presence and absence of diabetes and importantly, increases the efficacy of topically applied growth factors to promote healing. These results suggest that PTP1B inhibition may have utility treating chronic foot ulcers in diabetes.

Mesenchymal stem cells improve impaired foot ulcer healing in diabetic rats

J. Kato, H. Kamiya, T. Shibata, M. Kondo, T. Himeno, T. Okawa, E. Nakashima, A. Fukami, Y. Seino, S. Tsunekawa, N. Ozaki, Y. Hamada, K. Naruse, Y. Oiso, J. Nakamura;

Endocrinology and Diabetes, Nagoya University Graduate School, Japan.

Background and aims: Diabetes mellitus is one of the main causes of non-traumatic amputation of lower extremities, which substantially impair quality of life. Therefore, establishment of the treatment of foot ulcer in diabetic patients is required. Several therapies such as antiplatelet agents, prostaglandin analogues and/or local administration of bFGF have clinically been available as noninvasive treatment. Moreover, beneficial effects of mononuclear cell transplantation on foot ulcer have also been reported. It has been reported that mesenchymal stem cells (MSCs) produce and secrete various cytokines including VEGF and bFGF, which suggest that transplantation of MSCs would be useful for treatment of foot ulcer. Here we evaluated the therapeutic effects of MSC transplantation on impaired foot ulcer healing in the diabetic condition using a diabetic foot ulcer model and human keratinocytes (HKCs) primary cultured under the high glucose condition.

Materials and methods: 1) Isolation of MSCs: MSCs were isolated from bone marrow of 5 week-old SD rats. The characters and various growth factor producing abilities of MSCs were evaluated by FACS and RT-PCR, respectively. 2) HKC culture: HKCs were cultured under the 6 mM (NG) or 12 mM (HG) glucose condition with or without MSC-conditioned media (MSC-CM) for 72 hours. Cell viability was evaluated by MTS assay. 3) Diabetic foot ulcer model: Diabetes was induced by intraperitoneal injection of Streptozotocin to 6 week-old SD rats. After 8 weeks of diabetes, a full thickness 4mm diameter punch hole were created in the hind paw of normal (N) and diabetic rats (D). At the same time, 1×10^6 MSCs labeled with PKH were injected around the wounds. Wounds were photographed and the sizes of the remaining wounds were measured every other day. Blood flow on the wound beds (BF) was measured by laser Doppler flowmetry. Wounds samples were excised and histological evaluation was performed.

Results: 1) MSCs were positive for CD29 and CD90 and negative for CD34 and CD45. mRNA expressions of VEGF, bFGF, NGF, EGF and KGF were detected in MSCs. 2) HKC viabilities were significantly decreased under the HG condition (NG: $100 \pm 4\%$, HG: $87 \pm 4\%$ ($p = 0.02$)). MSC-CM significantly restored the impaired HKC viabilities under the HG condition (HG with MSC-CM: $192 \pm 21\%$ ($p < 0.01$ vs HG without MSC-CM)). 3) D showed significant hyperglycemia (N: 6.8 ± 0.2 mM, D: 24.1 ± 2.2 mM) and MSC transplantation did not affect glycemic levels. MSCs labeled with PKH were survived in dermal and subcutaneous tissues even three weeks after transplantation. At day 6, the percentage of wound area to original wound area was $62 \pm 1\%$ in N without MSC treatment (NC), $60 \pm 5\%$ in N with MSC treatment (NT), $76 \pm 4\%$ in

D without MSC treatment (DC) ($p=0.02$ vs NC) and $60\pm 2\%$ in D with MSC treatment (DT) ($p=0.02$ vs DC). Complete wound healing was observed at day 16.5 ± 1.8 in NC, 14.0 ± 1.2 in NT, 21.5 ± 1.1 in DC ($p=0.04$ vs NC) and 16.8 ± 0.7 in DT ($p=0.02$ vs DC). Decreased BF in DC was improved by MSC transplantation. Histological evaluation revealed the delayed wound reepithelialization in DC, which was ameliorated by MSC treatment.

Conclusion: These observations indicate that MSC transplantation would be useful for treatment of diabetic foot ulcer through not only ameliorating impaired microcirculation but also enhancing reepithelialization by keratinocytes.

Blocking notch pathway improves wound healing in diabetic mice

V.G. Sunkari, I. Botusan, S. Lindberg, J. Grunler, X. Zheng, K. Brismar, S.-B. Catrina;
Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden.

Background and aims: Wound healing is a complex process that needs coordination of several mechanisms such as cell proliferation, cell differentiation and angiogenesis. Diabetes has a repressive effect on wound healing and it is a high need for a better understanding of the pathophysiological pathways behind it in order to design new therapeutical approaches. The Notch system consists of several receptors (Notch 1-4) and ligands with a high specific cell dependent effect. The Notch signaling is activated after interaction between a ligand and one of the receptors. This interaction is transmitted intracellularly by a process involving proteolytic cleavage of the receptor by gamma-secretase complex. This results in the release of the intracellular domain of the Notch receptor (NICD) which translocates to the nucleus and activates several target genes. We have studied the modulation of the Notch pathway in diabetes having in mind the essential role played by the Notch system in the regulation of cell differentiation and angiogenesis.

Materials and methods: The effect of hyperglycemia on Notch system was studied *in vitro* in human dermal fibroblasts (HDF), mouse embryonic fibroblasts or in different animal models of diabetes (db/db mice and Goto-Kakizaki (GK) rat) using the appropriate method (western blot, Notch-responsive luciferase reporter gene assay or evaluation of target genes by quantitative RT-PCR). The functional consequences of the Notch system modulation were studied *in vitro* by the assessment of the migration of HDFs and by angiogenesis assay (using human endothelial cells). Notch pathway inhibition was induced either chemically with gamma-secretase inhibitors, (DAPT, L-685,458) or by specific siRNA silencing of the Notch receptors. The effect of the notch inhibition on wound healing was evaluated in db/db mice. Dermal punch biopsies were performed on the back of the animals and the wound healing rate was followed by digital photography. The angiogenesis was evaluated by lectin staining, the granulation tissue by hematoxylin & eosin staining and recruitment of endothelial precursors cells (EPCs) by QRT-PCR.

Results: Hyperglycemia activates Notch pathway at several levels as shown by increased NICD level, increased reporter gene activity and enhanced expression of several essential target genes as evaluated both *in vitro* and *in vivo*. The inhibitory effect of high glucose on migration of HDF and angiogenesis was cancelled by blocking the notch signaling with different gamma-secretase inhibitors (DAPT or L-685,458). Specific inhibition of different Notch receptors (1-4) by siRNA pointed out to a crucial role of Notch1 in migration and angiogenesis. Local treatment with gamma-secretase inhibitors (DAPT or L-685,458) improved the wound healing in db/db mice (Percentage of wound closure on day 12 was $60\pm 2\%$ (DAPT), $70\pm 4\%$ (L-685,458) and $43\pm 5\%$ (Placebo) respectively ($p<0.01$). Blocking Notch pathway in diabetic wounds was followed by increase in granulation and epidermal formation, increase in blood vessel formation and increase in expression of chemokine (SDF-1 alpha) responsible for better recruitment of EPCs.

Conclusion: Notch signaling was activated by hyperglycemia with deleterious effects on cell migration and angiogenesis. Blocking the overactive notch pathway by local treatment with gamma-secretase inhibitors improved wound healing rate in diabetic animal model.

Neurotensin and chitosan-based dressings: a new approach for diabetic wound healing treatment

L. Moura^{1,2}, A. Dias², E. Leal¹, H. Sousa², E. Carvalho¹;

¹Center for Neuroscience and Cell Biology, ²Chemical Engineering Department, Coimbra, Portugal.

Background and aims: Diabetes mellitus is one of the most widespread diseases in the world. It may cause chronic and non-healing diabetic foot ulcers (DFU) which decrease the welfare of patients. Recent studies indicated that some neuropeptides like Substance P, NPY, and CRH may act as inflammatory modulators and may improve the wound healing process. Natural biopolymers like chitosan, collagen and their derivatives, are presently receiving attention as wound dressing materials for wound healing applications. This is mostly due to some of their several favorable properties such as biocompatibility, biodegradability, non-toxicity and favorable biological behavior. Some chitosan derivatives such as N-carboxymethyl chitosan (CMC), N-carboxybutyl chitosan (CBC) and N-succinyl chitosan (SC) are known to be potential materials for wound healing applications. Employing these chitosan derivatives simultaneously as dressings and as platforms for the delivery of neuropeptides, such as, neurotensin (NT) has not yet been evaluated. This has been addressed in this work.

Materials and methods: Synthesis of CMC, CBC and SC: Chitosan reacted with glyoxylic acid, levulinic acid or succinic anhydride, for the synthesis of CMC, CBC and SC, respectively. *In vitro* release kinetics: Known amounts of a GSH solution (5mM) were loaded into previously weighted samples of each polymer. After drying, samples were immersed in PBS at different pHs at 37°C and for 8h. The quantification of released glutathione was based on the Ellman's Test. Release results with GSH were considered to choose polymeric samples for the Animal Model experiments. Animal model: Diabetes was induced by an intraperitoneal injection of 200mg/kg streptozotocin (STZ) dissolved in 200ml citrate buffer (pH 4.2) or buffer alone (non-diabetic mice). Control or STZ-treated mice were anesthetized and two 6 mm excision wounds, 2 cm apart, were created dorsally using a punch biopsy tool. CBC alone, NT alone (50ug/wound/per day), CBC loaded with NT (50ug/wound/per day) or PBS were placed daily on wounds and the progress of wound closure was monitored by acetate tracing up to 10 days.

Results: Release kinetics experiments showed that GSH release was not strongly affected by the release media pH (over a range between 6 and 8). However, SC presented a faster GSH release when compared with CMC and CBC at pHs of 6 and 7. In *in vivo* studies, CBC treated wounds showed a significant reduction in the wound area as compared to PBS treated wounds (29.5 %: $p<0.001$), wounds treated with NT alone also showed a reduction of (7.4%: $p<0.02$), while it is with the combination of the two treatments that we observed the greatest reduction in wound area (32.8%, $p<0.001$), already at 3 days post-wounding, in normal mice while in diabetic animals the observed differences are even more pronounced with the combined treatments showing a reduction of 39.8%, $p<0.001$. In addition, wounds treated with CBC and CBC plus NT, at day 10 in the same experiments, showed a smaller difference in wound reduction as compared to the PBS treated wounds at day 10.

Conclusion: Results demonstrated that CBC films incorporated with NT could be potentially advantageous as NT-releasing wound dressings for the treatment of diabetic foot ulcers.

Neurotensin decreases TNF alpha-induced cell death in keratinocytes and macrophages: possible important role in diabetic wound healing

E. Carvalho, V. Maio, E. Leal;

Center for Neurosciences and Cell Biology, University of Coimbra, Portugal.

Background and aims: Neuropeptides are known to be important in wound healing, particularly in diabetic wound healing. Although the role of neurotensin in wound healing is not well known. Moreover, a chronic inflammatory state in diabetes is responsible for the impairment of wound healing and tumor necrosis factor-alpha (TNF-alpha) appears to have an important role. In this study we aim to investigate the effects of neurotensin in TNF-alpha-induced changes in skin cells, keratinocytes and macrophages.

Materials and methods: Keratinocyte (HaCat) and macrophage (Raw 264.7) cell lines were incubated with 10ng/ml of TNF-alpha and/or 100 nM of neurotensin for 6 and 24h. We evaluated cell viability with the MTT assay and cell

death with nuclear staining (DAPI). Caspase-3, p38 MAPK, NF κ B activation and the detection of oxidized carbonyl groups were evaluated by western blot. Nitrosative stress was detected with nitrotyrosine staining.

Results: We found that 24h of incubation with TNF- α decreased HaCat and Raw cell viability ($78.7 \pm 4.0\%$ and $82.8 \pm 4.6\%$ of control, $p < 0.05$, respectively) and also caused cell death ($6.2 \pm 0.8\%$ and $4.3 \pm 0.3\%$ of total cells, $p < 0.05$, HaCat and Raw cells respectively). These effects were reverted by neurotensin. The active form of caspase-3 was found to be significantly increased with TNF- α in both cell types (HaCat, $p < 0.05$, $369 \pm 84.4\%$ of control; raw, $p < 0.01$, $329.2 \pm 50.4\%$ of control) and neurotensin decreased this activation suggesting that caspase-3 is involved in cell death. Neurotensin decreased TNF- α -induced activation of the p38 MAPK and NF κ B pathways. In addition, neurotensin decreased TNF- α -induced oxidative and nitrosative stress in skin cells.

Conclusion: Neurotensin inhibits the TNF- α -induced decrease in skin cell viability and cell death. The protective effects of neurotensin appear to be mediated by a decrease in oxidative and nitrosative stress, and by the inhibition of caspase-3, p38 MAPK and the NF- κ B pathways. These results suggest that neurotensin can have a protective role in chronic inflammatory conditions, particularly in chronic diabetic wounds.

Effects of Astragalus polysaccharides on the expression of MMP-2 and MMP-9 in human dermal fibroblasts derived from diabetic foot ulcers

C. Dingyu, X. Zhenghua, Z. Zhang, Z. Qian, Y. Qiling, H. Ling;
Endocrinology, Guangzhou Medical University, China.

Background and aims: The studies on the root of membranous milk vetch have showed that it can drain abscess out, promote the growth of cells and tissues, and recovered the function of dying cells. Astragalus Polysaccharides derived from the root of membranous milk vetch (*Astragalus membranaceus*) is still unclear for healing chronic diabetic foot ulcers whether the changes of diabetic ulcer fibroblasts can be reversed, whether the concentrations of MMPs can be reduced. We inquired into the effects of Astragalus Polysaccharides (AP) on the proliferation of fibroblasts (Fb), the activity and expression of MMP-2 and MMP-9 induced by IL-1 β in Fibroblasts from diabetic foot ulcers (DFU). The study was approved by the Hospital Ethics Committee.

Materials and methods: On the basis of analyzing the difference of IL-1 β between acute traumatic lesions in 9 patients with diabetes mellitus (DM) and 12 patients with DFU, The Fibroblasts proliferation, the activity and the expression of MMP-2, MMP-9 were tested After being incubated with different concentration of IL-1 β and AP.

Results: The concentration of IL-1 β in fluid from DFU was higher significantly than that of diabetic traumatic wounds ($p < 0.001$). Compared with the control group, 0.5–5ng/ml IL-1 β significantly stimulated fibroblasts proliferation, 50ng/ml IL-1 β were of no effect, 500ng/ml IL-1 β could inhibit fibroblasts proliferation. 50ng/ml IL-1 β +AP100 μ g/ml and 50 ng/ml IL-1 β +AP500 μ g/ml had positive effects on the fibroblast proliferation ($P < 0.001$). The activity of MMP-2, MMP-9 in 100 μ g/ml AP were lower significantly ($P = 0.006$) while the activity of MMP-2, MMP-9 in 50ng/ml IL-1 β were significantly higher than those in control group ($P = 0.000$). The level of MMP-2, MMP-9 protein expression in 100 μ g/ml AP was significantly lower ($P = 0.002$) and the level of MMP-2, MMP-9 protein expression in 50ng/ml IL-1 β was significantly higher than those in control group ($P = 0.0001$).

Conclusion: The AP not only promote the fibroblast proliferation, but also inhibit the activity and protein expression of MMP-2, MMP-9, might promote diabetic foot ulcers healing.

PS 107 Gestational diabetes mellitus: epidemiology and treatment

Efficacy of a two-step screening strategy for gestational diabetes in an area with a low prevalence of gestational diabetes and impact of the new IADPSG recommendation

K. Benhalima¹, M. Hanssens², R. Devlieger², P. Van Crombrugge³, J. Verhaeghe², C. Mathieu¹;

¹Diabetes & Endocrinology, ²Obstetrics and Gynecology, University Hospital Gasthuisberg, Leuven, Belgium, ³Diabetes & Endocrinology, OLV Hospital Aalst, Belgium.

Background and aims: IADPSG has suggested new diagnostic criteria for gestational diabetes (GDM). The impact of a universal screening strategy using an oral glucose tolerance test (OGTT) with more stringent diagnostic criteria for GDM has not been well defined in a population with a low background prevalence of GDM. The aim of our study was to evaluate the efficacy of our two-step screening strategy for GDM using a 50g glucose challenge test (GCT) and diagnosis for GDM based on the Carpenter and Coustan criteria using a 3-hour 100g OGTT and to evaluate the impact on GDM prevalence using the new recommendations.

Materials and methods: We retrospectively analyzed the two-step screening strategy for GDM from 2005–2010. The current policy in our university hospital advocates an universal screening with GCT between 24 and 28 weeks of pregnancy. We analyzed how many pregnancies received a GCT in our hospital and how many abnormal GCTs (≥ 140 mg/dl) were appropriately followed by an OGTT. We compared the GDM prevalence based on the two-step screening strategy with the GDM prevalence based on the new criteria.

Results: Over a six year period there were 12699 pregnancies (median number per year of 2090). Mean age of women was 30.8 ± 0.4 years, 90.3% were of Caucasian and 3.8% of Mediterranean descent. 17.1% were multiparous and 39% primigravid. 21.6% of women were overweight and 8.6% were obese. Of all pregnancies 53.0% (6726) received screening for GDM: 96.3% received a GCT and 3.7% an OGTT without previous GCT. Of the 6476 patients receiving a GCT, 16.4% (1065) had an abnormal test. Only 77.1% (821) of abnormal GCTs were followed appropriately by an OGTT. Of all OGTTs, 21% (222) showed GDM based on the Carpenter and Coustan criteria, leading to an overall prevalence of GDM of 1.7%. The prevalence of GDM in all 6726 tested pregnancies was 3.3%. The positive predictive value of GCT to have GDM was 20.3%. The number of pregnancies receiving an OGTT increased from 6.3% in 2005 to 12.3% in 2010 ($p < 0.0001$). The number of abnormal OGTTs, based on Carpenter and Coustan criteria, increased from 21.1% in 2005 to 25.8% in 2010 ($p = 0.312$). Using the new IADPSG criteria, 36.1% (382) of OGTTs showed GDM, leading to an overall prevalence of GDM of 3.0%. The prevalence of GDM in all 6726 tested pregnancies increased to 5.7%. Compared to diagnosis with the Carpenter and Coustan criteria, this led to a relative increase of 72.0% in the number of GDM diagnosed ($p < 0.0001$). The number of abnormal OGTTs based on the IADPSG criteria, increased from 36.2% in 2005 to 42.7% in 2010 ($p = 0.223$). Based on the IADPSG criteria, 36.1% of all GDM diagnosis was due to an elevated fasting plasma glucose.

Conclusion: Diagnosis of GDM in our hospital seems suboptimal as only half of the patients received a GCT and only two thirds of abnormal GCTs were appropriately followed by an OGTT. When the new criteria for GDM are used, the prevalence for GDM increases significantly but remains low despite the overestimation using the 100g OGTT. Advocating a universal screening strategy using an OGTT with the new criteria for GDM, might not be cost effective in a population with a low background prevalence of GDM. Risk based screening might be a more practical approach for such a population.

1175

Is there a seasonal variation in the incidence of gestational diabetes mellitus?

E. Anastasiou, E. Kyrtatzoglou, A. Athanasiadou, A. Giakoumi, S. Mouzakioti, V. Vasileiou, M. Alevizaki;
Alexandra Hospital 1st Endocrine Section - Diabetes Center, Athens, Greece.

Background and aims: Gestational diabetes mellitus (GDM) seasonability has been rarely addressed in literature, with conflicting results. The aim of the study is to evaluate monthly GDM incidence in a large group of Greek women examined during the past decade.

Materials and methods: 7618 pregnant women underwent a 3-hour, 100g OGTT during the 3rd trimester. For GDM diagnosis the ADA 2000 criteria were used. Seasonal and monthly GDM incidences as well as mean seasonal glucose levels during OGTT were calculated. Data for mean month temperature during the decade were obtained from the Hellenic National Meteorological Service. For the statistical analysis the following tests were used: χ^2 , odds ratio and MANOVA.

Results: GDM incidence, relative prevalence (RP) and odds ratio (OR-95%CI) per month, using January as a reference point, as well as mean monthly temperatures are shown in the Table.

Month	GDM%	RP	OR(95%CI)	Mean temperature C°
Jan	32.7%	1	relative to January	9.5
Febr	36.4%	1.11	1.21(0.94-1.56)	10.5
March	36.9%	1.13	1.24(0.97-1.58)	12
April	41.2%	1.26	1.42(1.11-1.82)	16
May	38.3%	1.17	1.31(1.03-1.65)	21
June	44.7%	1.36	1.60(1.26-2.04)	25
July	49.2%	1.50	1.88(1.49-2.38)	28
Aug	49.9%	1.52	1.84(1.42-2.37)	28
Sept	39.5%	1.21	1.41(1.11-1.79)	24
Oct	38.9%	1.19	1.29(1.02-1.65)	20
Nov	37.4%	1.14	1.25(0.98-1.59)	16
Dec	32.8%	1.00	1.02(0.79-1.32)	11.5

Seasonal GDM incidence was significantly different: Winter(W)= 28.1%, Summer(S)= 39.2%, Spring (Spr)= 32.4% and Autumn(A)= 32.4% ($\chi^2=51.0$, $p<0.0001$). The odds ratio for GDM incidence during summer was 1.65(95%CI:1.43-1.90), during spring and autumn 1.23 (95%CI:1.08-1.39) in relation to winter. Glucose levels (Glu) during OGTT were calculated. There was no statistical difference in fasting glucose blood levels. On the contrary, significantly increased blood glucose values were observed at 60', 120' and 180' in S vs W, while Spr and A values were intermediate (ANOVA: $p<0.0001$). Glu 60'(mg/dl): W= 162.8 \pm 41.9, Spr= 165.8 \pm 41.9, A= 166.9 \pm 39.4, S= 172.9 \pm 39.8, Glu 120'(mg/dl): W= 136.6 \pm 41.4, Spr= 137.9 \pm 40.6, A= 139.2 \pm 38.5, S= 146 \pm 40.3, Glu 180'(mg/dl): W= 108.6 \pm 33.2, Spr= 109.8 \pm 33.2, A= 111.1 \pm 32, S= 115.9 \pm 33.8. The effect of glucose on blood levels at 60', 120' and 180' remained an independent significant factor after adjustment for age, gestational age, BMI, weight gain during pregnancy, systolic and diastolic blood pressure (MANOVA model, $p<0.0001$).

Conclusions: GDM incidence in Greece presents seasonal variation. The risk for GDM diagnosis during summer is significantly increased (~70%) compared to winter. The differences in seasonal incidence are due to post glucose load levels variation, while no differences were found in fasting glucose levels. Whether the observed variations could be attributed to differences in ambient temperature (despite steady room temperature during the OGTT procedure), or other environmental and nutritional factors, remains to be clarified.

1176

Determinants of depressive symptoms in women screened for gestational diabetes 3 years after delivery

Z. Fehér¹, A. Pálfi¹, E. Szabó¹, R. Magenheimer¹, Á. Fürst¹, T. Tanczer¹, A.G. Tabák^{1,2}, G. Tamás¹;

¹1st Department of Medicine, Faculty of Medicine, Semmelweis University, Budapest, Hungary, ²Department of Epidemiology and Public Health, University College London, UK.

Background and aims: Recently it was suggested that increased blood glucose per se is not associated with an increased risk of depression while screen detected diabetes may cause psychological distress and a higher rate of depression. However it is not clear whether screen detected gestational diabetes has any long term mental consequences. Thus we set out to assess the association between the severity of depressive symptoms and previous gestational diabetes (pGDM) or current glucose status and to describe other determinants of depressive symptoms 3 years after delivery.

Material and methods: In a case-control study nested within a cohort of 3001 pregnant women who took part in a universal GDM screening program and delivered between 2005-2006. All 193 pGDM patients and 191 randomly selected controls with normal glucose tolerance (NGT) were invited for a clinical examination. Altogether 77 pGDM and 40 controls participated. Data on anthropometrics, socio-economic status, and lifestyles were collected. Depressive symptoms were screened by the 21-item Beck Depression Inventory (BDI). Current glucose tolerance status was determined according to a 75 g oral glucose tolerance test.

Results: PGDM patients were older ([mean \pm SD] 35.5 \pm 4.1 vs. 33.5 \pm 3.7 yrs, $P=0.01$), had higher fasting and 2-hour blood glucose (5.7 \pm 1.2 vs. 5.2 \pm 0.4 mmol/l, $P=0.004$; 6.6 \pm 2.1 vs. 5.1 \pm 1.3 mmol/l, $P<0.0001$), had higher systolic blood pressure (120 \pm 18 vs. 113 \pm 10 mm Hg, $P=0.03$), and were more frequently diagnosed with glucose intolerance (28.6% vs. 0%, $P<0.0001$) than controls, while body mass index (BMI) (25.6 \pm 5.7 vs. 23.9 \pm 3.7 kg/m²; $P=0.086$) and BDI scores (median[IQR], 5.0[7.0] vs. 4.5[7.8], $P=0.51$) were similar. BDI scores were significantly related to current job status (employed $r=-0.22$, $P=0.03$), higher education ($r=-0.21$; $P=0.02$), height (-0.27 , $P=0.003$), BMI (0.25; $P=0.006$), net income (<50 - 8.5[10.8] / 50-100 - 6.0[8.0] / 100-150 - 4.5[6.3] / 150-200 - 2.5[5.8] / > 200 thousand HUF - 0.5[2.0], $P=0.005$), marital status (married - 3[7] / single - 7[7] / living with a partner - 10[10], $P=0.02$) but were independent of glucose tolerance status ($r=0.06$, P NS). In multiple linear regression with BDI-score as the outcome, depressive symptom severity was independently related to lower family income, living with a partner (compared to single or married) and higher BMI (all $P<0.05$).

Conclusion: BDI scores were independent of screen detected GDM status and current glucose tolerance ~3 years after delivery. The main determinants of depressive symptoms were present socio-economic and marital status and measures of obesity.

Gestational diabetes mellitus in the Mediterranean region

J. Vassallo¹, C. Savona-Ventura², B. Karamanos³, M. Marre⁴, Mediterranean Group for the Study of Diabetes;

¹Division of Endocrinology & Diabetes, ²Department of Obstetrics & Gynaecology, University of Malta Medical School, Msida, ³2nd Medical Department, Diabetes Center Athens University, Greece, ⁴Diabetes, Endocrinology and Nutrition Department, Hôpital Bichat, Paris, France.

Background and aims: There is little available data on the prevalence and phenotype of GDM in populations in the Mediterranean region. The aim of this study was to characterise the phenotype of Mediterranean women at 24-32 weeks of pregnancy at risk of developing Gestational Diabetes Mellitus. (GDM) or suffering from GDM as diagnosed by a 75 g Oral Glucose Tolerance Test (OGTT).

Materials and methods: Participating centres in the Mediterranean region recruited 75-200 women per centre in the 24th-32nd week of pregnancy. The study protocol was approved by the relevant Research Ethics Committee in each participating country and informed consent was obtained from all study subjects. These women were assessed for the presence of risk factors such as elevated body weight, BMI, age, history of recurrent miscarriage, unexplained past stillbirth and macrosomia, irregular menses, need for assisted reproductive technology, hypertension (pre-existing, gestational or pre-eclampsia) and a family history of diabetes mellitus. The subjects subsequently underwent

a physical examination including height and blood pressure estimation, a 75 gram OGTT with a baseline fasting insulin level and HbA1c estimation. Insulin resistance was assessed using Homeostatic Model Assessment (HOMA-IR). Patients diagnosed with GDM were managed according to locally set protocols. Results are presented as mean \pm standard deviation. Comparisons of continuous variables between groups were made using independent-samples t-test and regression coefficients calculated categorical variables were compared using the Chi-squared test.

Results: 1210 patients from thirteen different Mediterranean countries were recruited to the study. 115 patients (9.5%) were identified as developing GDM using the ADA criteria, 256 (21.2%) according to WHO criteria and 341 (28.1%) using IADPSG criteria. Significant risk factors in this population for developing GDM were maternal age >35 years ($p=0.005$), pre-pregnancy BMI > 25 ($p=0.006$), diastolic BP > 90 mmHg ($p<0.0001$), PH of macrosomia ($p=0.006$) and FH of DM in first degree relatives (mother: $p<0.0001$; father: $p=0.02$; siblings: $p<0.0001$). These risk factors all had a high specificity but low sensitivity. Only pre-pregnancy BMI showed a moderate specificity (63.3%) and sensitivity (50.4%). Only fasting blood glucose showed any significant correlation with oGTT-AUC estimation ($r = 0.8$). There were no significant correlations established between BMI and the biochemical parameters (FBG, oGTT-AUC, HbA1c and HOMA-IR). Similarly no significant correlations were noted between the various biochemical parameters (HbA1c to insulin, HOMA-IR, oGTT-AUC; and FBG to HbA1c and HOMA IR).

Conclusion: The significant discrepancy in the prevalence of GDM depending on the diagnostic criteria used highlights the need for a consensus to be reached as to which GDM diagnostic criteria should be adopted in order to ensure best practice and best obstetric and neonatal outcomes without unnecessarily increasing the cost-benefit ratio.

Pregnancy outcomes in women with gestational diabetes treated with metformin or diet alone

J. Balani¹, S. Hyer¹, A. Rodin¹, H. Shehata²;

¹Diabetes Centre, ²Maternal Medicine, St Helier University Hospital, Surrey, UK.

Background and aims: Increasing evidence suggests that metformin may offer advantages in the management of gestational diabetes (GDM). We compared pregnancy outcomes in GDM women treated with either metformin or diet alone

Method: Prospective study of women attending our Diabetes Antenatal clinic. All patients received standardised dietary and exercise advice from a specialist dietitian. Patients performed home glucose monitoring aiming to achieve target glucose values (fasting <5.6mmol/l, 1h post-prandial <8mmol/l, 2h post prandial <7mmol/l). If 3 or more values were outside target range, treatment with metformin 500mg bd was added and the dose titrated up to a maximum of 2500mg/day. Pregnancy outcomes were recorded and results compared for diet or metformin-treated patients.

Results: We studied 266 GDM women (mean \pm SD); age: 33 ± 5.4 yrs) treated with metformin and 130 (age 33 ± 5.2) managed with diet alone. Women on diet alone had significantly lower body mass index (BMI) kg/m² (27 ± 6 vs 30 ± 7 ; $p<0.01$), HbA1c % (5.4 ± 0.5 vs 5.6 ± 0.7 ; $p<0.01$) and oral glucose tolerance test values (fasting glucose 4.8 ± 0.6 vs 5.2 ± 0.9 ; $p<0.01$; 2h glucose 8.6 ± 1.8 vs 7.9 ± 1.6 ; $p<0.001$). More women in the metformin group were induced at term (27% vs 16%; $p=0.03$), and were delivered by elective Caesarean section (19.9% vs 13.1%; $p=0.04$). Macrosomia (birth weight >90th centile) was dramatically reduced in metformin treated patients (11.3% vs 21.5%; $p<0.01$) as was small for gestational age (BW<10th centile) 7.9% vs 16.2%; $p=0.01$). Neonatal hypoglycaemia was less frequent in metformin treated mothers (7.1% vs 15.2%; $p<0.01$). Mean birth weight, admissions to neonatal unit, congenital malformations and shoulder dystocia rates were similar.

Conclusions: Despite greater glucose intolerance in the metformin group at baseline, neonatal outcomes were better compared with those on dietary measures alone. These results add to accumulating evidence that metformin is beneficial in the management of GDM.

Association of gestational diabetes mellitus with dietary intake of macro- and micro-nutrients

N. Sultana¹, N. Rosy², F. Jebunnesa³, R. Helal⁴, L. Ali³;

¹Dept of Biochemistry & Cell Biology, BIRDEM, ²Dept of Gynecology and Obstetrics, BIRDEM, ³Dept of Biochemistry & Cell Biology, Bangladesh Institute of Health Sciences (BIHS), ⁴Dept of Gynecology and Obstetrics, Bangladesh Institute of Health Sciences (BIHS), Dhaka, Bangladesh.

Background and aims: Gestational Diabetes Mellitus (GDM) is the commonest metabolic disorder of pregnancy and it substantially increases the maternal as well as fetal mortality and morbidity. It is well known that dietary practices are linked to glucose intolerance; however, the role of diet in the pathogenesis of GDM has not yet been adequately studied. The present study was undertaken to investigate the association of GDM and its basic defects with the dietary intake of few macro- and micro-nutrients.

Materials and methods: Under a case-control design 89 GDM subjects along with 101 pregnant controls were investigated for their age, BMI, blood pressure, glycemic status (fasting and 2 hr blood glucose, HbA1c), lipid profile (TG, Chol, LDL and HDL) and insulinemic status (C-peptide). GDM was diagnosed following the WHO Guideline. Dietary intakes of both the groups were assessed by Food Frequency Questionnaire. Serum glucose was measured by glucose oxidase method, lipids by enzymatic method and HbA1c was measured by HPLC-based autoanalyzer. Serum C-peptide was measured by chemiluminiscent 'ELISA' and insulin secretion (HOMA%B) and sensitivity (HOMA%S) were calculated by homeostasis model assessment. Data were analyzed by appropriate univariate as well as multivariate analysis

Results: Serum TG and C-peptide were found to be significantly higher in GDM group compared to control. HOMA%B did not differ between the groups, but HOMA%S was substantially less in GDM [Median (Range), 46 (26-90)] as compared to control [124 (49-299); $p<0.001$]. Total energy intake was about 1.5 times higher in GDM [Kcal, 2550 (1135-3675) as compared to control [1600 (1005-3700); $p<0.001$]. The higher calorie intake was contributed by all the 3 major energy sources is carbohydrate [g/day, GDM control 335(139-462) vs 200 (130-389); $p<0.001$], fat [60 (23-98) vs 20 (11-40); $p<0.001$], and protein [90 (70-199) vs 87 (70-196); $p=0.005$]; however, the proportionate rise of fat intake (about 3 times) was much higher in GDM compared to the other two nutrients. The intake calcium, iron, Vit B1 and Vit C did not differ between the two groups, but Vit B2 intake was significantly higher in GDM [μ g/day, 1.30 (0.20-2.78)] as compared to control [1.19 (0.34-2.74); $p=0.041$]. On logistic regression analysis GDM was found to be associated with total carbohydrate intake ($p<0.001$) and it was strongly associated with total fat intake ($p<0.001$). HbA1c and HOMA%S were also found to be strongly associated with total fat intake ($p<0.001$) on logistic regression analysis. On multiple regressions HbA1c showed significant association with Vit B2 intake ($p=0.018$).

Conclusion: In conclusion, GDM and its basic defects seem to have strong association with energy, fat intake and carbohydrate and riboflavin intake may also have some association with these defects.

Vitamin D levels and glucose homeostasis in pregnancy

A.M. Ramos-Leví¹, M.J. Torrejón², E. Bordiu¹, M.D. Fernández¹, A.L. Calle-Pascual¹;

¹Endocrinology and Nutrition, ²Laboratory, Hospital Clínico San Carlos, Madrid, Spain.

Background and aims: Recent reports have described the non-classical effects of vitamin D and its deficiency has been associated to an increase in the risk of several pathologies. So far, however, data regarding the role of vitamin D in the development of gestational diabetes mellitus (GDM) are inconsistent. Our study evaluates maternal serum 25-hydroxy-vitamin D (25-OH-D) at 24-28 weeks of gestation and its correlation with glucose homeostasis.

Materials and methods: Measurements from 228 pregnant women (mean age 33 [29-36]) were taken at the time of O'Sullivan test during the months of June - September 2010 at the San Carlos Clinical Hospital in Madrid, Spain. When the O'Sullivan test was positive, a 100 g glucose-tolerance test (OGTT) was performed. Women were diagnosed as diabetic or non-diabetic using the Coustan and Carpenter criteria. Serum 25-OH-D and other parameters of glucose metabolism were assessed. A demographic and lifestyle questionnaire was performed.

Results: Mean serum 25-OH-D was 19.15 ± 9.16 ng/ml. Insufficiency (<30 ng/ml) and deficiency (<10 ng/ml) was reported in 92.2% and 15% of the participants, respectively. No significant differences in 25-OH-D levels (19.28 ng/ml vs. 19.13 ng/ml, $p=0.939$) or in the rate of insufficiency (95.8% vs. 91.7%, $p=0.481$) were found in diabetic vs. non-diabetic pregnant women. However, a correlation was observed between 25-OH-D levels and glucose homeostasis (table 1). Serum 25-OH-D was 21.34 ng/ml in European women and 16.71 ng/ml in South-American women ($p<0.0001$). GDM prevalence was greater amongst the first ones (18.3% vs. 6.2%, $p=0.025$), who were also older and presented a greater increase in weight.

Conclusion: Hypovitaminosis D is frequent during pregnancy. Low concentrations of serum 25-OH-D were associated to higher fasting serum glucose levels (FSG), 1h-OGTT glucose level, HbA1c values and homeostasis model assessment index (HOMA-IR). The role of vitamin D in GDM deserves further investigation.

Table 1: Values show median (Q1–Q3).

25-OH-D ng/ml (n)	<10 (32)	10–19.9 (98)	20–29.9 (74)	>30 (23)
FSG mg/dl	89 (84–93)	87 (82–92)	84 (79–89)	82 (79–87)
1h-OGTT mg/dl	162 (130–185)	155 (130–185)	152 (127–172)	145 (133–164)
HbA1c %	5.3 (5–5.4)	5.1 (4.9–5.3)	5.0 (4.9–5.3)	4.9 (4.9–5.2)
HOMA-IR	1.6 (0.9–2.7)	1.4 (0.8–2.9)	1.3 (0.9–2.9)	1.0 (0.6–1.7)

FSG: fasting serum glucose; HOMA-IR: homeostasis model assessment index equation (used as the insulin resistance index).

Maternal vitamin D metabolism in gestational diabetes mellitus: a systemic review

S. Li, F. Yan, H. Tian;

Department of Endocrinology and Metabolism, West China Hospital, Sichuan University, Chengdu, China.

Background and aims: Vitamin D metabolism has been considered an important impact factor of type 1 and type 2 diabetes mellitus, while it remained unclear whether vitamin D impact the incidence of gestational diabetes mellitus (GDM). We are aimed to investigate the vitamin D metabolic status in GDM.

Materials and methods: We systemically collected observational studies of maternal vitamin D status in GDM from MEDLINE (1950–2010) and EM-Base (1950–2010).

Results: Six case-control studies have been finally included for a meta-analysis. Serum 25-(OH)-Vitamin D3 level, which describes the overall status of vitamin D, in pregnant women with GDM was significantly lower than those with normal glucose tolerance (NGT, overall MD -6.72 nmol/L, 95%CI -11.42 to -2.01 nmol/L, $P=0.005$). Vitamin D deficiency (serum 25-(OH)-Vitamin D3 < 50 nmol/L) was more frequently detected in GDM patients compared with normal pregnant women (overall OR 1.82, 95%CI 1.27 to 2.62, $P=0.001$). However, in pregnant women with impaired glucose tolerance (IGT), the decreased level of vitamin D (overall MD -8.86 , 95%CI -20.13 to 2.41 , $P=0.12$) and vitamin D deficiency (overall OR 2.40, 95%CI 0.79 to 7.29, $P=0.12$) did not reach statistical significance.

Conclusion: In conclusion, serum 25-(OH)-Vitamin D3 level and vitamin D deficiency is significantly associated with gestational diabetes mellitus, but not IGT in pregnancy.

Figure: Vitamin D deficiency is more commonly found in pregnant women with gestational diabetes mellitus (GDM) compared with those with normal glucose tolerance (NGT)

Vitamin D deficiency is related to the severity of gestational diabetes mellitus (GDM)

V. Vasileiou, A. Athanasiadou, E. Kyratzoglou, A. Giakoumi, M. Alevzaki, E. Anastasiou;

1st Endocrine Section- Diabetes Center, Alexandra Hospital, Athens, Greece.

Aim: In a previous study we found a significant relation between vitamin D deficiency and fasting glucose levels during pregnancy. The aim of the present study was to further evaluate the relation of vitamin D levels and GDM in a larger group, using the new IADPSG criteria.

Patients and methods: In a prospective study 348 Greek pregnant women aged 30 ± 5.7 years underwent a 75g OGTT in the third trimester of pregnancy (27.4 ± 4.2 w), during which serum 25(OH)D, PTH, Ca, and P concentrations were also measured. GDM was diagnosed using the IADSPG criteria (adopted by ADA in 2011). For 25(OH)D deficiency a cut-off point of 20 ng/ml was chosen. Age, height, pre-pregnancy weight, BMI and blood pressure (BP) were recorded. HOMA-IR was calculated. 25(OH)D was converted to its natural logarithm (Ln). For the statistical analysis we used: χ^2 , ANOVA, Pearson's linear correlation and multiple linear regression.

Results: 25(OH)D deficiency was found in 196 out of 348 pregnant women (56%). No difference was found between normal (20.1 ± 7.1 ng/ml) and GDM (19.7 ± 7.5 ng/ml) women ($p = 0.592$). However pregnant women with 3 abnormal glucose values in the OGTT ($n=35$) presented with significantly lower levels of 25(OH)D compared to those with one ($n=82$) or two abnormal values ($n=53$) and normal ($n=152$) pregnant women (16.3 ± 5.7 vs 20.9 ± 7.7 , 20.1 ± 7.9 , 20.1 ± 7.1 ng/ml respectively, $F=3.4$, $p<0.018$). The relationship remained significant after adjustment for BMI, age, gestational age and seasonal variation. In this group the odds ratio for 25(OH)D deficiency was 2.43 (95% CI: 1.1–5.4). Ln-25(OH)D was negatively correlated with fasting plasma glucose ($r = -0.108$, $p=0.047$). Pregnant women with fasting hyperglycemia presented with lower 25(OH)D levels ($p=0.027$). Additionally Ln-25(OH)D was negatively correlated with HOMA-IR ($r = -0.134$, $p<0.05$). Multiparous pregnant women (≥ 2 parities) presented with significantly higher prevalence of 25(OH)D deficiency compared to nulliparous and women with one parity (75% vs 56% and 51% respectively, χ^2 for trend: 7.938, $p = 0.019$). The odds ratio for 25(OH)D deficiency in multiparous women was 2.5 (95% CI: 1.2–5.2), adjusted for BMI. We confirmed the expected negative correlation of Ln-25(OH)D with PTH ($r = -0.285$, $p<0.01$) and also with systolic ($r = -0.114$, $p=0.037$) and diastolic BP ($r = -0.164$, $p=0.003$).

Conclusion: No association was found between 25(OH)D deficiency and the presence of GDM; however, we found a relation with the severity of GDM, as expressed by the presence of three abnormal glucose values. Interestingly, multiparous women (≥ 2 parities) presented with a threefold increased risk for being vitamin D deficient. These two findings have not been previously reported.

PS 108 Gestational diabetes: risk factors and outcomes

Obesity induced by high fat diet before and during gestation: evaluation of maternal and offspring repercussions on metabolic parameters

L. Ratheau^{1,2}, S. Ros¹, N. Jeandier^{1,2}, W. Bietiger¹, E. Seyfritz¹, M. Pinget^{1,2}, S. Sigrist¹

¹Centre Européen d'Etude du Diabète, ²UdS, pôle NUDE, Hôpitaux Universitaires de Strasbourg, France.

Background and aims: Obesity and metabolic syndrome are increasing worldwide in children. Long term effects on offspring metabolism of the fetal intrauterine environment due to “metabolic imprinting” are to be evaluated and physiopathologic mechanisms are still misunderstood. High Fat Diet (HFD) during gestation and lactation promotes obesity and insulin-resistance in rat offspring. We created a model of obesity and metabolic syndrome using a HFD containing 21.4% of fat, this to be closer to physiological clinical models. The aim of this work was to study the metabolic status of our model in females, in order to define the consequences of obesity, independently of hyperglycemia, on maternal and offspring pancreas.

Materials and methods: Fourteen female Wistar rats (200g) were randomized in two groups and fed, 3 months before mating, either with Normal Diet (ND) or with HFD. At the end of gestation the rats underwent either abdominal or normal delivery. After delivery, rats were fed with ND during the 3 weeks of lactation and weaning, until sacrifice at 6 weeks of life. Before mating, during gestation and lactation, metabolic parameters were assessed on mothers and offspring. We performed histological analysis of pancreatic islets in 6 weeks-old offspring.

Results: In mothers, weight gain was significantly higher in the HFD group after 2 months, associated with higher leptin concentrations (12.1 ± 4.9 vs 6.5 ± 2.5 ng/ml, $p = 0.04$). After 3 months, in HFD rats IpGTT showed significantly increased C-peptide levels (2155.9 ± 434.9 vs 1307.7 ± 295.8 pM, $p = 0.01$) and glycemia (1.2 ± 0.4 vs 0.7 ± 0.2 g/l, $p = 0.01$) whereas fasting glycemia staid comparable in the 2 groups (0.7 ± 0.1 vs 0.7 ± 0.1 g/l), reflecting a glucose metabolism abnormality and insulin resistance. After 16 days of gestation, IpGTT showed comparable glycemia at baseline and after stimulation and C-peptide levels tended to be higher in HFD (t0 637.4 ± 426 vs 390.2 ± 211 pM, and t60 2853.5 ± 1806 vs 2058.1 ± 1328 pM). At birth, offspring weight was lower in HFD, but took rapidly over to be comparable at 6 weeks (sacrifice). Glycemia was significantly lower at weaning in HFD offspring (0.9 ± 0.1 vs 1.1 ± 0.2 g/l, $p = 0.01$), but tended to increase at 6 weeks (1.4 ± 0.3 vs 1.3 ± 0.1 g/l, $p = 0.11$) associated with a tendency to lower C-peptide (562.1 ± 89.9 vs 713.8 ± 388 pM, $p = 0.45$). C-peptide/glycemia were respectively 382.8 ± 100 vs 495.3 ± 280 ,

$p = 0.32$. Preliminary results of histological pancreatic islets analyze showed a tendency to hyperplasia and hypotrophy in HFD offspring.

Conclusion: This model showed that, mild HFD induced obesity, a normal fasting glycemia and increased stimulated glycemia associated to increased C-peptide in female Wistar rats. As already published in other HFD models, glucose metabolism improved during gestation with comparable glycemia with controls, confirming our model as obesity and insulin resistant. HFD offspring glycemia and weight were lower at birth and increased to comparable levels at 6 weeks, associated with a tendency to lower C-peptide concentrations, corresponding to the histological islets anomalies found. Due to the poor carbohydrate composition of mother milk, offspring insulin secretion becomes significant only after weaning. The impact of mother's obesity on offspring pancreatic β -islets histology and oxidative stress remains to be evaluated.

ATLANTIC-DIP: raised maternal body mass index (BMI) adversely affects maternal and foetal outcomes in glucose tolerant women classified using International Association of Diabetes and Pregnancy Study Groups (IADPSG) criteria

M.C. Denney, G. Avalos, M.W. O'Reilly, E.P. O'Sullivan, F. Dunne; Medicine, NUI, Galway, Ireland.

Background and aims: Raised maternal body mass index (BMI), in association with hyperglycaemia is associated with adverse pregnancy outcome. Whether BMI has an independent effect on adverse pregnancy outcome is not clear. We aimed to investigate the effects of raised maternal BMI on pregnancy outcome in glucose tolerant women, classified using the IADPSG criteria.

Materials and methods: Prospective observational study of pregnancy outcome in a cohort of women attending an antenatal clinic recruited to a universal screening programme for gestational diabetes. Maternal outcomes included glucose, delivery mode, pregnancy induced hypertension (PIH), pre-eclampsia (PET), antepartum hemorrhage (APH) and postpartum hemorrhage (PPH). Fetal outcomes included birthweight, congenital malformation, fetal death, neonatal jaundice, hypoglycemia and respiratory distress. Analyses performed using stepwise logistic regression and decision trees. Analyses adjusted for maternal age, parity, cigarette smoking and ethnicity.

Results: Increasing maternal BMI was associated with adverse pregnancy outcomes: higher cesarean section rates, pre-eclamptic toxemia, pregnancy induced hypertension, increased birth weight and congenital malformation. The association of normal range glucose with adverse pregnancy outcome was weak and did not interact with the effects of raised BMI. A BMI threshold of 28 kg/m² was associated with a significant rise in adverse pregnancy outcome. Adverse obstetric outcome in association with raised BMI was greater in primiparous women.

Conclusion: Raised maternal BMI, within the overweight range, is associated with adverse pregnancy outcomes. These adverse effects of BMI occur independently of maternal glucose.

Maternal and Neonatal Outcomes: a $p < 0.01$; b $p < 0.05$

Predicting normal birth weight using serial foetal abdominal circumference measurements and maternal risk factors in gestational diabetes mellitus

K.J.H. Neff¹, B.T. Kinsley^{1,2}, S. Daly²;

¹Mater Misericordiae University Hospital, ²Coombe Women and Infants University Hospital, Dublin, Ireland.

Background and aims: Our study aimed to determine the role for serial fetal abdominal circumference measurements (ACMs) in predicting normal birth weight and macrosomia (birth weight > 4kg) in pregnancies complicated by gestational diabetes mellitus (GDM).

Materials and methods: This prospective cohort study reviewed 137 women diagnosed with GDM on a 100g glucose tolerance test (GTT) who delivered a singleton pregnancy at term. All women had at least 2 ACMs taken in the third trimester. Those who delivered a macrosomic infant were compared to those who did not. The ACMs, maternal risk factors and fetal birth weight were recorded. We tested ACM trends and maternal risk factors both in combination and individually for associations with fetal birth weight using regression analysis. This data was used in predictive models.

Results: A total of 326 ACMs from 137 pregnancies were analysed. They differed significantly at each gestational age when comparing the macrosomic group (N=35) and non-macrosomic group (N=102). Women in the MG had significantly greater fasting glucose measurements on diagnostic GTT (6.6mmol/l \pm 0.7 Vs 5.9mmol/l \pm 1.0, $p=0.019$) and maternal weight at delivery (96kg \pm 17 Vs 90kg \pm 17, $p=0.039$), and were more likely to have a history of macrosomia (60% Vs 31%, $p=0.001$). Serial ACMs below the 50th centile could predict normal weight delivery with 100% positive predictive value. Serial ACMs below the 75th and 90th percentiles in non-obese women without a history of macrosomic delivery identified normal weight delivery with a 98% and 96% positive predictive value respectively. Serial ACMs above the 75th centile could predict macrosomia with a sensitivity of 74%.

Conclusion: Serial ACMs can predict normal weight delivery in GDM when used in a risk factor based model. Serial ACMs are more useful for predicting normal birth weight than macrosomia in GDM.

1186

Comparison of pregnancy outcome between obese and non-obese women with gestational diabetes intensively treated

T. Vidal-Trécan¹, N. Chastang¹, M. Halbron¹, C. Ciangura¹, O. Bourron¹, C. Sachon¹, D. Vauthier-Brouze², A. Laubiès², M. Dommergues², A. Hartemann¹, S. Jacqueminet¹;

¹Diabetologia and Metabolic Diseases, ²Obstetrics and Gynaecology, Pitié-Salpêtrière Hospital, Paris, France.

Background and aims: We sought to compare the maternal and foetal outcomes of gestational diabetes between obese women (body mass index (BMI) >30kg/m²) and non obese women.

Materials and methods: From 1999 to 2009, we recruited all women with gestational diabetes treated and followed-up in Pitié-Salpêtrière hospital. The management approach included: self-monitoring blood glucose 6 times/daily, diet therapy plus insulin if metabolic goals were not reached (fasting blood glucose levels < 90mg/dl and 2-hour postprandial blood glucose levels < 120mg/dl). Pregnancy outcome variables included weight gain during pregnancy, cesarean section delivery, macrosomic or large-for-gestational age infants and a composite outcome for all neonatal complications.

Results: One thousand and forty eight women were enrolled. We compared 288 obese women (BMI 33.5kg/m²) to 752 non obese women (BMI 24.2 kg/m²). Obese women were likely older (33.14 vs. 32.43, $p=0.05$), non Caucasian (61.4% vs. 60.2%, $p<10^{-4}$) and multiparous (75.6% vs. 64.4%, $p<0.001$). They had more previous macrosomic newborns (20.3% vs. 10.3%, $p<10^{-4}$), more previous cesarean section delivery (23.7% vs. 11.6%, $p<10^{-4}$) and more previous gravid hypertension (5.9% vs. 2.8%, $p=0.03$). They had higher fasting blood glucose (0.96g/l vs. 0.92g/l, $p<10^{-4}$). Obese women were likely treated earlier (28.7 SA vs. 31.1 SA, $p<10^{-4}$), and insulin-treated (33.3% vs. 22.8%, $p=0.001$). They gained less weight (9kg vs. 13kg, $p<10^{-4}$) and had more cesarean delivery section (44% vs. 29.1%, $p<10^{-4}$). Their newborns were more likely macrosomic (14.3% vs. 9%, $p=0.02$) or large-for-gestational age (20.9% vs. 13.3%, $p=0.005$) and had more neonatal complications (10.3% vs. 6.6%, $p=0.005$). Multivariate logistic analysis (comprising age, fasting blood glucose and previous obstetrical complications), for women without previous cesarean delivery, confirmed that obesity was an independent risk factor of cesar-

ean delivery (OR=2.0 [IC95% 1.2-3.5] $p=0.01$). For women without previous macrosomic newborns, obesity was an independent risk factor of large-for-gestational age (independent of fasting blood glucose) only for women who were not insulin-treated (OR=1.9 [1.1-3.5], $p=0.04$). For macrosomic infant, the risk was not significant ($p=0.21$).

Conclusion: Our study showed that obesity increased the maternal and foetal complications of gestational diabetes, although obese women had an earlier care and a closer follow-up. However, insulin may partly reduce the risk of large-for-gestational age newborns.

Characteristics and pregnancy outcome in obese and non obese women with gestational diabetes

	Obese (n=288)	Non obese (n=752)	p
Age (years)	33.14 (21-49)	32.43 (14-49)	0.05
BMI (kg/m ²)	33.5 (30-61)	24.2 (15.2-29.9)	<10 ⁻⁴
Insulin treatment (%)	86 (33.3)	155 (22.8)	0.01
Weight gain (kg)	9 (-13-35)	13(0-39)	<10 ⁻⁴
Cesarean section (%)	122 (44)	213 (29.1)	<10 ⁻⁴
Macrosomic infants (%)	40 (14.3)	66 (9)	0.02
Large-for-gestational age (%)	58 (20.9)	98 (13.5)	0.005
Neonatal complications (%)	28 (10.3)	47 (6.6)	0.05

1187

Children born to women with prior gestational diabetes are predestinated to be overweight at a young age

C. Nilsson¹, A. Carlsson², M. Landin-Olsson¹;

¹Department of Endocrinology, ²Department of Pediatrics, Institution of Clinical Science, Skåne University Hospital, Lund, Sweden.

Background and aim: Gestational diabetes mellitus (GDM) occurs as a complication in between 1 to 14% of all pregnancies and it is well known that the disease increases the risk for macrosomia and caesarean delivery. Additional to these early complications, it is recently described that children born to these mothers have a future risk of overweight and obesity. The aim of this study was to follow-up BMI in GDM children and in their siblings.

Material: Between 1995-2000 we had 204 pregnancies with GDM in our region in South Sweden and 114 of these accepted to participate in the study. Longitudinal data regarding weight and height of the offspring together with siblings born to women who had pregnancies complicated with GDM were collected from health care centres and schools. The body mass index (BMI) of these children was then compared to reference values from the background population in Sweden.

Results: When comparing BMI of children born after a GDM pregnancy with BMI in their siblings, there was no difference at any age. Index children and siblings were therefore merged together (n=153) and compared to Swedish reference BMI values (n=1318-3650). No difference was found at birth, at age 1-2 yrs the children to GDM mothers had significantly lower BMI in both sexes and thereafter without difference until the age of 4 yrs in girls and 6 yrs in boys when higher BMI were found in GDM children. At the age of 10 the mean BMI of girls (n=62) was 18.8 and in boys (n=70) 18.1 compared to 17.0 ($p<0.001$) and 16.9 ($p<0.001$) respectively in controls.

Conclusion: Children to mothers with GDM gained less in weight during the first years of life. At age 4-6 yrs weight increased and these children had significantly higher BMI compared to background population. It is most likely that this is due to life style habits of the families rather than prenatal factors, since the same BMI pattern was found in siblings. Lifestyle intervention should therefore have priority in these families.

1188

Influence of gestational diabetes mellitus on weight outcome in twin pregnancies

M.A. Guillén, L. Herranz, J. Riveiro, B. Barquiel, L. Pérez, L.F. Pallardo; Endocrinología y Nutrición, Hospital Universitario La Paz, Madrid, Spain.

Background and aims: Gestational diabetes mellitus (GDM) complicates about 8.8 % of all pregnancies and it is associated with increased risk of adverse perinatal outcomes, including increased birth weight. Multiple birth rate is about 3% of all births, and it has an increasing pattern in the last decades due to the rising maternal age and increasing use of fertility treatments. Twin preg-

nancies have a higher risk for most adverse outcomes compared to singletons. Although GDM is clearly associated with macrosomia, its influence on weight outcome (including macrosomia, growth restriction and growth discrepancy), in twin pregnancies is not clear. We aimed to evaluate the influence of gestational diabetes mellitus on weight outcome in twin pregnancies.

Materials and methods: 2976 women with GDM who attended the Diabetes and Pregnancy Unit of our hospital from 1986 to 2009 were included (2922 singleton and 54 twin pregnancies). GDM was diagnosed based on National Diabetes Data Group criteria. Spanish birthweight charts for singleton and twin pregnancies were used to ascertain the rate of large for gestational age infants (LGA) and the rate of small for gestational age infants (SGA). Infant weight birth ratio (actual weight at birth/50th percentile weight for sex and gestational age) was also used to assess weight outcome. Growth discrepancy was defined as more than 20% of birthweight difference between twin newborns. Pregnancy outcomes for singleton GDM and twin GDM pregnancies were compared using the independent-samples Student's *t* test for quantitative variables and the chi-square or Fisher exact test for categorical variables. The Mann-Whitney-U test was used for comparisons between the twin GDM pregnancies.

Results: Women affected by GDM with twin pregnancies did not significantly differ from singleton pregnancies concerning body mass index (24.1 ± 4.0 vs 24.8 ± 4.7 ; $p = 0.331$), risk factors at diagnosis (1.9 ± 0.9 vs 1.90 ± 1.04 ; $p = 0.827$), fasting glucose at diagnosis (88.5 ± 14.8 vs 90.5 ± 14.6 ; $p = 0.328$), treatment with insulin (38.9 vs 49.1 %; $p = 0.088$), insulin dose (0.33 UI/kg ± 0.16 vs 0.28 ± 0.14 ; $p = 0.174$), and HbA_{1c} achieved at third trimester (5.1 ± 0.4 vs 5.1 ± 0.5 ; $p = 0.592$). Women with twin pregnancies were older (34.4 ± 5.0 vs 33.0 ± 4.4 ; $p = 0.018$), gained more weight during pregnancy (13.8 ± 5.2 vs 9.8 ± 4.2 ; $p = 0.000$), had less parity (1.7 ± 0.7 vs 2.1 ± 1.2 ; $p = 0.000$), and less gestational age at delivery (37.1 ± 1.8 vs 38.8 ± 1.2 ; $p = 0.000$). There was no difference in the incidence of LGA infants in twin GDM pregnancies compared to singleton GDM pregnancies (13.0 vs 7.6 %; $p = 0.189$) nor in the incidence of SGA (13.0 vs 14.9%; $p = 0.847$). Infant weight birth ratio was similar for twin GDM pregnancies and singleton GDM pregnancies (0.98 vs 0.98; $p = 0.729$). 13% of all twins had weight discrepancy of >20%. Fasting glucose at diagnosis was similar in mothers with discordant and not discordant twins (88.7 ± 10.6 vs 88.5 ± 15.6 ; $p = 0.780$). HbA_{1c} achieved in third trimester was higher in mothers of discordant twins (5.3 ± 0.2 vs 5.0 ± 0.4 ; $p = 0.031$).

Conclusion: Gestational diabetes mellitus has the same impact on weight outcome in newborns from singleton and twin pregnancies. Moreover, poor glycaemic control during pregnancy may have an influence in growth discrepancy in twins. Therefore it is important to treat twin GDM pregnancies using the same standards we use for singleton pregnancies in order to avoid adverse outcomes.

1189

Low BMI at age 20 years predicts gestational diabetes independent of BMI in early pregnancy: Tanaka Women's Clinic Study

Y. Yachi^{1,2}, C. Horikawa¹, Y. Heianza¹, A. Sugawara¹, A. Saito¹, K. Fujiwara¹, I. Nishibata³, M. Yasuhara⁴, K. Kobayashi⁴, S. Kodama¹, K. Saito¹, Y. Tanaka⁵, H. Sone¹;

¹Department of Endocrinology and Metabolism, University of Tsukuba Institute of Clinical Medicine, Mito, ²Department of Lifestyle Medicine, Ochanomizu University, Tokyo, ³Nursing department, Kawasaki City College of Nursing, ⁴Department of Obstetrics and Gynecology, Maternity Fitness Association, Tokyo, ⁵Department of Obstetrics and Gynecology, Tanaka Women's Clinic, Tokyo, Japan.

Background and aims: Maternal obesity and weight gain since early adulthood are known predictors of gestational diabetes (GDM) in Western countries. However, their impact has not been evaluated well in Asia where mean BMI levels are generally lower than in Western countries. Rather, thinness due to the desire to be slim like fashion models has been a major health problem among East Asian women of childbearing age. Especially, Japanese women have been reported to strongly desire to be thin, even though they have a lower BMI than other ethnic groups. In fact, more than 20% of women in their 20s are underweight in Japan. We therefore examined associations of BMI at age 20 years (BMI_{20y}) and BMI change since the age 20 years with risk of GDM in Japanese pregnant women.

Materials and methods: Prospectively observed were 624 consecutive pregnant women without recognized diabetes before the pregnancy who initially visited the obstetric clinic before 13 weeks gestation. Weight at age 20 years was self-reported. Baseline height and weight measurements were obtained at the initial obstetric visit. We calculated BMI in each at the time of age 20 years

and baseline. GDM was diagnosed by the International Association of Diabetes in Pregnancy Study Group's criteria. Logistic regression was performed, adjusting for relevant covariates.

Results: Twenty-eight women developed incident GDM. Mean age of participants was 33.4 ± 3.7 y and mean gestation at the first visit was 8.0 ± 2.0 wks. Mean baseline BMI and BMI_{20y} were 19.8 ± 2.1 and 19.0 ± 1.7 , respectively. Mean the change in BMI from age 20 to baseline age (BMI change) was 0.8 ± 1.7 . By multivariate logistic regression analysis that included maternal age, parity, baseline BMI and BMI_{20y}, we observed a statistically significant inverse association between BMI_{20y} and GDM incidence (odds ratio (OR), 0.68; 95%CI, 0.51-0.92). Compared with women in the highest 3 quartiles of BMI_{20y} (BMI_{20y}≥18), women in the lowest quartile of BMI_{20y} (BMI_{20y}<18) had a 4.84-fold (2.03-11.57) higher risk for GDM. When the BMI change replaced BMI_{20y} in the model, BMI change was associated with an increased risk of GDM (OR 1.47; 1.09-1.98). Women in the highest quartile of BMI change who gained 1.85 or more units had a 3.05-fold (1.18-7.93) greater risk than those in the lowest 3 quartiles. When we focused on the threshold of risk of GDM, women with the lowest quartile of BMI_{20y} had a 6.30-fold (2.26-17.59) greater risk compared with women in both the highest 3 quartiles of BMI_{20y} and the lowest 3 quartiles of BMI change.

Conclusion: Although a subsequent BMI gain from age 20 was an independent risk factor for GDM, lower BMI_{20y} was more strongly associated with an elevated GDM risk.

Gestational diabetes mellitus results in a higher prevalence of small for gestational age babies

G. Avalos, L.A. Owens, C. Dennedy, E.P. O'Sullivan, M.W. O'Reilly, F. Dunne; Department of Medicine, National University of Ireland, Galway, Ireland.

Background and aims: Gestational Diabetes Mellitus (GDM) is associated with increased foetal and maternal morbidity and mortality. Previous studies have shown that babies of diabetic mothers are more likely to be large for gestational age (LGA). This retrospective study aimed to assess whether the converse may also be true, that there may also a higher rate of small for gestational age (SGA) amongst babies of mothers with GDM.

Materials and methods: This retrospective study offered universal screening for GDM to pregnant women in 5 hospitals between 2007-2009. During this time 5,500 women underwent testing for GDM using a 75g Oral Glucose Tolerance Test at 24-28 weeks gestation. GDM was defined by the International Association of the Diabetes and Pregnancy Study Groups guidelines (IADPSG).

Results: The prevalence of GDM was 12.4%. 4.5% of babies were small for gestational age (SGA) at birth in live births. Babies of mothers with GDM were more likely to have SGA than babies of non-diabetic women, OR 1.5, $p = 0.03$, 95% CI {1.02-2.24}. Mean Body Mass Index (BMI) was lower in mothers of SGA babies than mothers of babies who were average (AGA) or large for gestational age (LGA), 26.3 compared to 27.1, $p < 0.0001$. Smoking (OR 3.1, $p = 0.000$) pre-eclampsia (OR 3.99, $p = 0.000$), gestational hypertension, low parity (OR 0.8, $p = 0.005$), non-Caucasian ethnicity were also predictive of SGA. These SGA babies had a worse clinical outcome, including; higher caesarean section rate, higher requirement for neonatal intensive care, higher rates of hypoglycaemia and respiratory distress. 76% of diabetic women were treated with insulin. Insulin treatment did not affect rates of SGA when compared with dietary management.

Conclusion: This study shows another important negative outcome associated with GDM. Further research is required to identify the causative factor(s).

1191

Clinical outcomes of patients with gestational diabetes mellitus who do not have typical risk factors

S.K. Nijjar¹, K.F. Hunt¹, H. Rogers¹, C. Smith², C.M. Gayle¹, M.S. Marsh², S.A. Amiel¹, P. Choudhary¹;

¹Diabetes and Metabolism, ²Obstetrics, Kings College Hospital, London, UK.

Background and aims: The UK's NICE guidelines recommend screening for Gestational Diabetes Mellitus (GDM) only in women with risk factors: BMI >30 kg/m², previous macrosomic baby or GDM, family history of diabetes, and South Asian, black Caribbean and Middle Eastern ethnicity. This study

aimed to identify the proportion of patients with GDM without such risk factors, who would not be screened for GDM by NICE guidance, in our ethnically diverse urban population (23% African/Caribbean; 4% South Asian; 73 white European and “other”). We also evaluated the impact of “typical” risk factors on maternal and fetal outcomes; and of the impact of The International Association of Diabetes and Pregnancy Study Groups (IADPSG) guidelines on risk factor based screening for GDM.

Materials and methods: From a retrospective cohort analysis of 70 GDM women, delivered between January and December 2010, we ascertained the incidence of recorded risk factors; maternal outcomes (treatment requirement, maternal complications, mode of delivery and postpartum oral glucose tolerance test (OGTT) values) and fetal outcomes (macrosmia, small for gestational age (SGA), fetal complications and admission to neonatal intensive care unit (NICU)) to examine the impact of risk factors on outcomes. The effect of using the IADPSG 2-hour diagnostic value in the OGTT (8.5 mmol/l vs. 7.8 mmol/l from WHO criteria currently in use) on the proportion of women with no risk factors was also calculated.

Results: 15.7% of GDM women had no GDM risk factors and 27% of these required insulin therapy to achieve our glucose targets for pregnancy. Ethnicity (61.4%), family history of diabetes (50%), and BMI (47.1%) were the commonest risk factors associated with GDM in our population but ethnicity was the only risk factor in 15.4%. 37.1% of GDM women had BMI <25, and of these, 34.6% had no other risk factors. The incidence of fetal complications was not different between women without and with risk factors: hypoglycaemia (57.6 vs 54.5% $p=0.85$); neonatal jaundice (30.5 vs 36.4% $p=0.70$); respiratory distress (13.2 vs 18.2% $p=0.81$) and shoulder dystocia (1.7 vs. 0% $p=0.66$). The incidence of maternal complications was not statistically different between those with and without risk factors, (hypertension (0 vs. 10.2% $p=0.31$); hypoglycaemia (0 vs. 1.7% $p=0.66$) and polyhydramnios (0 vs. 1.7% $p=0.66$)). The number of maternal risk factors for GDM was significantly correlated with higher A1c at diagnosis ($r=0.319$; $p=0.007$) and at delivery ($r=0.289$; $p=0.015$). 27.3% of women with no risk factors, and 24.5% of women with 1 or more risk factors would not be diagnosed GDM using the 2-hr threshold recommended by IADPSG.

Conclusion: 15.7% of women with GDM have no predisposing risk factors. Children born to these women have a similar risk of complications as those with established risk factors and their diagnosis may have been missed or delayed if a risk factor based screening strategy were employed. A similar proportion of those with and without risk factors would be missed if the new IADPSG recommended 2-hr glucose threshold was used to diagnose GDM. These data suggest that in our population a risk factor based screening programme would put a significant proportion of babies at risk.

1192

The risk of postpartum maternal hyperglycaemia in women with gestational diabetes is reduced by breastfeeding

M.W. O'Reilly, G. Avalos, M.C. Kennedy, E.P. O'Sullivan, F. Dunne;
Endocrinology/Diabetes Mellitus, University College Hospital, Galway, Ireland.

Background and aims: Gestational diabetes (GDM) is associated with adverse fetal and maternal outcomes. It identifies women at risk of pre-diabetes, type 2 diabetes (T2DM) and cardiovascular risk in later life. Recent studies have suggested that breastfeeding may confer a beneficial effect on postpartum maternal glucose tolerance in both women with GDM and normal glucose tolerance (NGT) in pregnancy.

Materials and methods: We compared results from 300 women with GDM and 220 women with NGT according to IADPSG criteria using a 75g oral glucose tolerance test (OGTT) at 24–28 weeks gestation by repeating the 75g OGTT postpartum to reassess glucose status. We also tested for postpartum metabolic syndrome (MetS) according to international criteria. Binary logistic regression was used to identify maternal factors that increased the risk of persistent glucose intolerance. Postpartum lactation status was categorised as breastfeeding alone, bottle-feeding alone, or both.

Results: 520 women were tested. OGTT results were classified as normal (FPG<5.6 mmol/l; 2h<7.8 mmol/l) or abnormal (IFG; 5.6–6.9, IGT; 2h 7.8–11.0, IFG+IGT; T2DM FPG $\geq 7 \pm 2$ h ≥ 11.1). Six of 220 (2.7%) women with NGT in pregnancy had postpartum dysglycaemia compared to 57 of 300 women (19%) with GDM in pregnancy ($P<0.001$). Non-Caucasian ethnicity (OR 3.40, 95% CI 1.45–8.02, $P=0.005$), family history of T2DM (OR 2.14, 95% CI 1.06–4.32, $P=0.034$) and insulin use in pregnancy (OR 2.62, 95% CI 1.17–5.87, $P=0.019$) were all predictive of persistent dysglycaemia. MetS was present postpartum in 31 of 300 women (10.3%) with GDM compared to 18

(8.2%) of 220 women with NGT ($P=0.4$). The prevalence of persistent dysglycaemia was lower in women who breast-fed versus bottle-fed their babies, or employed both techniques (7.1% v 18.4% and 11.2%, respectively, $p<0.001$).

Conclusion: In this Irish population the prevalence of persistent glucose intolerance in women with GDM in pregnancy is 19% compared to 2.7% in NGT women. Breast-feeding confers a beneficial effect on postpartum glucose tolerance. The precise mechanism behind this association is unclear and requires further study.

Table 1: Prevalence of persistent postpartum dysglycaemia according to breast-feeding status

	Prevalence of persistent dysglycaemia (%)
Breast-fed only n=212	15 (7.1%)
Bottle-fed only n=201	37 (18.4%)*
Breast+bottle n=107	12 (11.2%)

* $P<0.001$

PS 109 Gestational diabetes mellitus: biomarkers

1193

Metabolic fingerprinting of gestational diabetes mellitus

D. Dudzik^{1,2}, M. Ciborowski^{3,4}, W. Zarzycki², M. Skotnicki⁵, M. Żórawski¹, K. Malinowska⁶, B. Zarzycka², S. Dzienis², K. Popławska², R. Wiśniewska¹, C. Barbas⁴, M. Górski²

¹Department of Pharmacology, ²Clinical Department of Endocrinology, Diabetology and Internal Diseases, ³Department of Physical Chemistry, Medical University of Białystok, Poland, ⁴CEMBIO (Center for Metabolomics and Bioanalysis) Pharmacy Faculty, San Pablo University, Madrid, Spain, ⁵Clinical Department of Perinatology, Public Clinic Hospital, Medical University of Białystok, ⁶Department of Gynecology, J. Śniadecki's District Hospital, Białystok, Poland.

Background and aims: Metabolomics is a rapidly evolving discipline of the comprehensive measurement of ideally all endogenous metabolites in a biological fluid. LC-QTOF-MS with an electrospray interface has advantages of sensitivity, mass accuracy, and good potential for biomarker identification, what makes this technique very important tool in metabolomics. Gestational Diabetes Mellitus (GDM) is a growing problem and increasingly common complication of pregnancy, however pathogenesis of GDM is not yet fully recognized. Application of LC-MS based metabolic fingerprinting to study plasma profiles of healthy pregnant women in comparison to those with GDM and 3 months postpartum with GDM in pregnancy seems to be a good approach to find metabolites responsible for the evolution and complications of this disease.

Materials and methods: Serum of 20 pregnant healthy women mean age 26 yrs, 20 pregnant women with diagnosed GDM after a 2-h 75-g OGTT, mean age 29 yrs and 20 women 3 months postpartum with GDM during pregnancy, mean age 29 yrs. Data were collected in positive ESI mode in separate runs on a QTOF (Agilent 6520) operated in full scan mode from 50 to 1,000 m/z. A matrix data has been aligned and filtered. Each group has been filtered separately applying 90 % Filter by Flags, it means that masses present in at least 90 % (18 out of 20) of the samples passed the filtering. To select metabolites characteristic to each group we used Venn diagram.

Results: There was found 21 metabolites characteristic only to GDM in comparison to other groups. In the group of women 3 months postpartum we observed still 31 metabolites characteristic for GDM. Those masses were putatively identified using several databases like HMDB, Metlin, KEGG, and LipidMaps.

Conclusion: Our research suggests that identified compounds indicate for alteration of fatty acids amides, lipids, and carnitines metabolism in gestational diabetes which may be important in the gestational diabetes mellitus pathogenesis. With metabolomic approach we observed, that 3 months postpartum there are still changes in metabolism connected with previous GDM.

1194

Elevated serum selenium concentrations in gestational diabetics compared to control pregnant women: cause or consequence?

Z. Garamvölgyi¹, K. Balogh², M. Mézes², N. Adányi³, N. Solymosi⁴, J. Rigó¹, J. Molnár⁵

¹1st Department of Obstetrics and Gynaecology, Semmelweis University Medical School, Budapest, ²Department of Nutrition, Szent István University, Gödöllő, ³Central Food Research Institute, Budapest, ⁴Szent István University, Gödöllő, ⁵National Institute of Food and Nutrition Science, Budapest, Hungary.

Background and aims: High serum selenium concentrations were positively associated with the prevalence of type 2 diabetes according to recently published data from the Third National Health and Nutrition Examination Survey. Moreover, an intervention study from the US, in which diabetes was a secondary outcome in the parent trial, concluded that oral selenium supplementation may increase risk for type 2 diabetes. As the role of selenium in gestational diabetes (GDM) has not yet been investigated, the aim of this study was to compare serum selenium concentrations, serum insulin and the activity of the selenium-dependent enzyme glutathione peroxidase (GPX) in different blood compartments of gestational diabetic (n=61) and control pregnant women (n=45) between the 24th and 28th week of pregnancy.

Materials and methods: All blood samples were obtained when study participants were screened for GDM according to WHO guidelines. All study participants filled in a detailed questionnaire and reported their intake of vitamin supplements. Serum selenium concentration was measured by hydride generation atomic absorption spectrometry. Plasma, red blood cell and whole blood hemolysate total GPX activity were determined by an end-point direct enzyme-assay in the presence of reduced glutathione and cumene-hydroperoxide as co-substrates. For insulin measurements, an automated immunoassay based on electro-chemiluminescence was used. Statistical analysis was performed using the Wilcoxon rank sum test and logistic regression.

Results: There was no difference in age between the two groups of pregnant women. BMI was slightly higher in gestational diabetic women than in controls (25.3±5.9 vs. 22.9±4.2 kg/m², p=0.009). The intake of vitamin supplements was similar in both groups of pregnant women. Serum selenium concentrations were significantly higher in gestational diabetic (50.8±12.8µg/l) compared to control pregnant women (40.8±7.8µg/l, p=0.0009) and selenium levels showed a significant positive association with the incidence of gestational diabetes even when adjusted for age and BMI (p=0.000227, OR: 1.09, 95% CI: 1.04–1.14). Red blood cell GPX activity was higher in gestational diabetic than in control pregnant women (7.16±2.14 vs. 5.92±0.67 U/g protein, p=0.02). Serum selenium concentrations correlated with plasma GPX activity in control pregnant women (p=0.005) but not in gestational diabetics. Serum insulin levels, HOMA-IR, plasma and whole blood total GPX activity did not differ between the two groups of pregnant women.

Conclusion: Gestational diabetics have significantly higher serum selenium concentrations than control pregnant women at the time of diagnosis, before starting dietary modifications. As some prenatal vitamins contain selenium, their selection requires consideration after risk factors for GDM have been assessed in the first trimester of pregnancy. Further studies may determine whether elevated selenium levels are a cause or consequence of GDM and whether selenium may play a specific role in gestational diabetes.

1195

Plasma phospholipid fatty acid composition and desaturases indices in women with gestational diabetes mellitus before and after delivery

G. Sartore, M. Dalfrà, A. Barison, R. Marin, N.C. Chilelli, S. Burlina, A. Lapolla;

Medical and Surgical Sciences, University of Padova, Italy.

Background and aims: Plasma phospholipid fatty acid (PPFA) composition is affected not only by dietary fat intake, but also by endogenous fatty acid metabolism, which is regulated by enzymes such as elongases and desaturases. Desaturating enzymes, stearoyl-CoA desaturase (SCD, also known as Delta-9 desaturase), and Delta-5 desaturase (D5D) modulate fatty acid composition and are associated with insulin resistance. SCD is the rate-limiting enzyme in the biosynthesis of monounsaturated fatty acids. D5D is a key enzyme in polyunsaturated fatty acid, such as arachidonic (AA, 20:4n-6) and docosahexaenoic (DHA, 22:6n-3), metabolism. During pregnancy there is increased demand for the polyunsaturated fatty acids, AA and DHA. Furthermore, in type 1 and 2 diabetes, the activity of D5D is impaired. Therefore, we investigated the possibility that, in gestational diabetes mellitus (GDM), fatty acid composition in plasma phospholipids and desaturases indices may be altered before or after delivery. Moreover, we measured some parameters of inflammation, such as C-reactive protein (CRP), and interleukin-6 (IL-6), and investigated their relationship with desaturase indices in GDM and control women.

Materials and methods: Venous blood samples were obtained from 22 women with GDM and from 23 controls, during the third trimester of pregnancy and 6 months after delivery. We used a validate food questionnaire to determine the intakes during and after pregnancy. PPFA composition was analysed by gas chromatography.

Results: Dietary assessment of the GDM and control women did not provide evidence of a difference in intake between the two groups. During pregnancy also no difference in PPFA composition was observed between the two groups, while 6 months after delivery a significant increase in stearic acid (18:0) was found in the GDM women compared with the control subjects (12.83±0.96 vs 13.98±1.37; p=0.005). The D5D activity increased 6 months after delivery in controls (2.66±0.79 vs 3.15±0.70; p=0.040), while remained unchanged in GDM. Conversely, SCD index appears significantly decreased after pregnancy in GDM in comparison with the third trimester (p=0.001) and also with controls (p=0.024). In the last ones SCD index remained unchanged after delivery. In regards to the relationship between inflammatory markers and desaturases, only SCD index was found significantly correlated to PCR and IL-6, both during the third trimester and after pregnancy in GDM women.

Conclusion: In our study, the PPFA composition during the third trimester of pregnancy does not appear different between control and GDM women, while after delivery there are only minimal changes. In contrast to other reports, the data from the current study do not provide evidence of the impairment of D5D in GDM. Another important finding of the present study is that SCD activity seems regulated not only by dietary, hormonal and environmental factors, as well known, but also by GDM. In addition, our results suggest a relationship between fatty acid metabolism and inflammatory marker modulation in GDM.

1196

White blood cell count is an independent predictor of gestational diabetes mellitus

T. Tanczer^{1,2}, R. Magenheimer¹, G. Tamás^{1,2}, M. Papp^{1,2}, Z. Fehér^{1,2}, Á. Fürst^{1,2}, A. G. Tabák^{1,3}

¹1st Department of Medicine, Semmelweis University Faculty of Medicine,

²National Centre for Diabetes Care, Budapest, Hungary, ³Department of Epidemiology and Public Health, University College London, UK.

Background and aims: Subclinical inflammation and insulin resistance are thought to be involved in the development of type 2 diabetes. Much less is known about first trimester role of inflammatory markers as predictors of subsequent GDM.

Material and methods: Using the data collected during a population-based screening program of gestational diabetes (WHO criteria 1999) in Budapest, Hungary we undertook a case-control study nested within a cohort of all screened women. Cases were all GDM women delivered between 01.01.2005 and 31.08.2008 (n=397) controls were metabolically healthy women delivered between 01.01.2006 and 31.03.2006 (n=317). After the exclusion of women with missing covariates (n=179) and women with previous GDM (n=56) the final sample included 234 cases and 249 controls. We investigated the association between prepregnancy and early pregnancy markers and the risk of gestational diabetes.

Results: GDM women were older (31.7 ± 4.3 [mean \pm SD] vs. 30.0 ± 4.3 yrs, $p < 0.0001$), had higher body weight (66.0 ± 14 vs. 64.0 ± 11.2 kg, $p = 0.031$), BMI (24.2 ± 4.8 vs. 23.1 ± 4.2 , $p = 0.01$), fasting blood glucose (4.5 ± 0.6 vs. 4.3 ± 0.6 mmol/l, $p < 0.0001$), and WBC count (9.2 ± 2.0 vs. 8.5 ± 1.9 G/l, $p < 0.0001$) and had a lower stature (165.2 ± 6.0 vs. 166.5 ± 5.8 cm, $p = 0.016$). They presented more frequently with a positive family history of diabetes (29.1% vs. 7.7%, $p < 0.0001$). According to a multiple logistic model the independent predictors of GDM were WBC count (OR=1.20 / 1 G/l, 95%CI [confidence interval]: 1, 07-1.34), height (OR=0.965 / 1 cm, 95%CI: 0.93-1), fasting blood glucose (OR=1.55 / 1 mmol/l, 95% CI: 1.07-2.25), age (OR=1.08 / 1 year, 95% CI: 1.03-1.14), and a positive family history of diabetes (OR=4.73, 95%CI: 2.56-8.77).

Conclusion: We found that first trimester white blood cell count was an independent predictor of the development of gestational diabetes suggesting that subclinical inflammation may be involved in the development of gestational diabetes. Further epidemiological studies are needed to investigate whether markers of subclinical inflammation - together with other known risk factors - could improve early detection of gestational diabetes.

Suppressor of cytokine signalling 1 and 3 expression in fat and placental tissue from women with gestational diabetes

B. Telejko¹, M. Kuzmicki², N. Wawrusiewicz-Kurylonek¹, A. Lemaneiewicz³, D. Lipinska¹, A. Citko¹, J. Pliszka¹, J. Wilk¹, A. Kretowski¹, J. Szamatowicz², M. Górski¹

¹Department of Endocrinology, Diabetology and Internal Medicine,

²Department of Gynecology, ³Department of Perinatology, Medical University of Białystok, Poland.

Background and aims: The suppressor of cytokine signaling (SOCS) proteins are feedback inhibitors of signaling pathways induced by cytokines, hormones and growth factors. Moreover, experimental data suggest that SOCS expression is a determinant of basal insulin signaling and a potential mediator of cytokine-induced fat tissue insulin resistance. Elevated SOCS3 mRNA expression has been shown in subcutaneous adipose tissue obtained from obese subjects and patients with type 2 diabetes, whereas no data concerning SOCS expression in pregnant women with the disturbances of glucose tolerance are so far available.

Materials and methods: In the present study we measured SOCS1 and SOCS3, as well as interleukin-6 (IL-6), IL-8 and leptin mRNA expression in paired samples of subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT) and placental tissue obtained from 18 pregnant women with normal glucose tolerance (NGT) and 20 subjects with gestational diabetes mellitus (GDM), using RT-PCR.

Results: SOCS1 and SOCS3 mRNA were detectable in all samples studied but their expression in fat and placental tissue did not differ significantly between the women with and without GDM. The patients with GDM had significantly higher IL-8 mRNA expression in VAT than had the women with NGT ($p = 0.007$), whereas the expression of IL-6 and leptin mRNA did not differ markedly between the two groups. SOCS1 mRNA expression in placental tissue was significantly higher than in SAT ($p = 0.002$) and VAT ($p = 0.01$), while SOCS3 mRNA expression in placental tissue was significantly lower than in fat tissue ($p = 0.0002$). Stepwise regression analysis revealed that SOCS3 mRNA expression in SAT and VAT was significantly related to IL-6 mRNA expression ($\beta = 0.86$, $p = 0.01$, $R^2 = 0.21$ and $\beta = 0.89$, $p = 0.02$, $R^2 = 0.85$, respectively), whereas SOCS3 mRNA expression in placental tissue was significantly predicted by HLD-cholesterol level ($\beta = 0.48$, $p = 0.01$) and IL-8 mRNA expression ($\beta = 0.42$, $p = 0.045$, $R^2 = 0.58$).

Conclusion: In conclusion, our results do not show significant differences in SOCS1 and SOCS3 mRNA expression in adipose and placental tissue obtained from pregnant women with and without GDM. This might be explained by the lack of differences in the expression of IL-6, which seems to play an essential role in the induction of the genes encoding SOCS proteins.

Unfavourable cytokine profile and increase of oxidative stress during and after pregnancy in women with gestational diabetes mellitus

C. López-Tinoco¹, M. Roca², F. Vilchez¹, A. García-Valero¹, J. Bartha³, M. Aguilar-Diosdado¹

¹Endocrinology, Hospital Puerta del Mar, Cádiz, ²Endocrinology, Hospital Virgen de la Victoria, Málaga, ³Obstetrics, Hospital Puerta del Mar, Cádiz, Spain.

Background and aims: Although gestational diabetes mellitus (GDM) may represent a transient form of a latent metabolic syndrome (MetS) that might become evident later, little evidence demonstrating an association between early cardiovascular disease (CVD) markers and GDM has been shown. The aim of the study was to identify the presence of early markers of metabolic and CVD, as proinflammatory cytokines and oxidative stress status, in patients with GDM during pregnancy and after delivery.

Materials and methods: We performed a prospective case-control study within a sample of a total of 126 pregnant women (63 with GDM, 63 controls), reassessing with intrasubject analysis 41 women with a history of GDM (cases) and 21 controls, in the postpartum period. We analyzed demographic data, perinatal and obstetrics results and the levels of cytokines [measured in plasma using a commercial kit for multiplex analysis (Luminex® 100 LINCO plex Kit, St Louis, MO, EEUU)] and the markers of oxidative stress and antioxidants status [measured in serum or plasma using a commercial kit (Cayman Chemical, Ann Arbor, MI, USA)], during 24th and 29th week of gestation and twelve months after delivery.

Results: In the univariate analysis, were found statistically significant differences in the pregestational body mass index (BMI) ($p = 0.001$), levels higher of TNF- α ($p = 0.002$), leptin ($p = 0.001$), lipoperoxides [LPO] ($p = 0.04$), and lower of adiponectin ($p = 0.04$), catalase ($p = 0.04$) and superoxide dismutase [SOD] ($p = 0.001$) between cases and controls. The cesarean rate was 40% in cases and 10% in controls ($p = 0.001$). Multivariate analysis that was performed using non-conditional logistic regression showed adiponectin and catalase having a protective effect against (OR=0.9, $p = 0.02$, OR=0.39, $p = 0.006$, respectively) and the BMI and LPO carried a significant risk for GDM (OR=8.4, $p = 0.01$, OR=2.44, $p = 0.034$, respectively). At 12 months postpartum, there were significant differences in BMI ($p = 0.013$), fasting glucose ($p < 0.001$), glucose 120 min ($p = 0.007$), HOMA ($p = 0.002$), leptin ($p = 0.023$) and catalase ($p = 0.01$) between cases and controls. In the intrasubject analysis, fasting glucose and glucose 120 min levels decreased significantly in cases ($p = 0.04$) and controls ($p < 0.001$), TNF- α levels significantly increased both in cases ($p = 0.001$) and controls ($p = 0.001$) as well as the LPO and catalase levels, which increased in cases ($p = 0.001$ and $p = 0.001$, respectively) and controls ($p = 0.001$ and $p = 0.001$ respectively).

Conclusion: Women with GDM have more risk to have increased CVD markers, expressed at higher levels of TNF- α , LPO and lower of catalase and SOD. This unfavorable cytokine profile and increased oxidative stress, which remains in the postpartum period, evidence that women with a history of GDM have a permanent state of metabolic dysfunction that would make them more likely to develop DM2 and CVD in the future.

Lipid peroxidation is raised in gestational diabetes: correlation with glucose levels

K.C. Lewandowski¹, N. Stojanovic², M. Karbownik-Lewinska¹;

¹Department of Endocrinology & Metabolic Diseases, The Medical University of Lodz, Poland, ²Department of Endocrinology & Diabetes, Queen's Hospital, Romford and Holly House Hospital Essex, London, UK.

Background and aims: Overproduction of reactive oxygen species (ROS) and free radicals, reflected in an increased concentration of lipid peroxidation (LPO) products results in enhanced oxidative stress and can lead to several diseases. There are, however, few data on concentrations on alteration of LPO products in gestational diabetes mellitus (GDM).

Materials and methods: Fasting concentrations of malondialdehyde + 4-hydroxyalkenals (MDA + 4-HDA), as an index of LPO were measured in 50 women at 28 weeks of gestation. The study group was divided according to the results of 50g glucose challenge test (GCT) and 75g oral glucose tolerance test (OGTT): Controls (n=20): normal responses to both GCT and OGTT, Intermediate Group (IG) (n=15): false positive GCT, but normal OGTT and GDM group (n=15): abnormal both GCT and OGTT. Insulin resistance was assessed by HOMA and Insulin Resistance Index (IRI) derived from glucose and insulin levels during OGTT.

Results: There were no significant differences between the subgroups, regarding age ($p=0.67$) and BMI, both before ($p=0.54$) and during pregnancy ($p=0.47$). The principal differences between women with GDM and controls pertained to glucose levels at 120 minutes of OGTT, that fell within the range typical for impaired glucose tolerance in all but one subjects with GDM, while fasting glucose levels (albeit still higher than in controls, $p \leq 0.01$) were still within the reference range for all but one women with GDM. There was no difference in the estimates of insulin resistance assessed by IRI between the Controls and Intermediate groups (0.68 ± 0.25 versus 0.93 ± 0.29 , $p=0.23$). There was, however, a marked difference in value of IRI between the GDM and Intermediate group (1.67 ± 0.39 versus 0.93 ± 0.29 , $p=0.015$), and between GDM group and Controls ($p<0.001$). LPO concentrations [MDA+4-HDA(nmol/mg protein)] were significantly higher in women with GDM (64.1 ± 24.3 (mean \pm SD), 39.3 ± 23.1 , 47.0 ± 18.1 , for GDM, intermediate and normal glucose tolerance controls, respectively, $p<0.05$), but there were no differences in LPO concentrations between Controls versus Intermediates. There was a significant correlation between concentrations of LPO products and glucose levels at 120 minutes of OGTT ($r_s = 0.42$, $p = 0.009$).

Conclusion: Concentration of lipid peroxidation products are raised in women with gestational diabetes and correlate with glucose concentrations even within the range considered to represent impaired glucose tolerance in non-pregnant subject. Physiological significance of this phenomenon still remains to be elucidated.

Circulating vascular endothelial growth factor receptor-1 (SVEGFR-1) and receptor-2 (SVEGFR-2) in euglycaemic gestational diabetes

P.G. Halvatsiotis¹, P. Karakitsos², K. Patsouras³, M. Alepaki², L. Batalias³, D. Kassanos³, G. Dimitriadis¹;

¹2nd Department of Internal Medicine - Propaedeutic, ²Department of Cytopathology, ³3rd Department of Obstetrics and Gynecology, Athens University Medical School, Greece.

Background and aims: Gestational diabetes mellitus (GDM) is a pathological state of carbohydrate intolerance beginning or first recognized during pregnancy, when left untreated increases the risk of adverse pregnancy outcome. GDM is associated with a significantly increased incidence of preeclampsia (PE), a severe complication of pregnancy, which is also related to an imbalance between angiogenic and anti-angiogenic factors as the soluble Vascular Endothelial Growth Factor Receptor-1 (sVEGFR-1). There is a paucity on information on the role of the soluble Vascular Endothelial Growth Factor Receptor-2 (sVEGFR-2) but lower levels are linked inversely

proportional to the progression of pre-eclampsia. Thus the aim of our study was to investigate if the presence of GDM is related with changes in the serum concentrations of these factors.

Materials and methods: sVEGFR-1 & sVEGFR-2 levels were measured in serum of 12 women with GDM ($32,08 \pm 1,59$ yo) and 9 matched for BMI (before pregnancy), race and age nondiabetic mothers (NGD) ($29,5 \pm 1,84$ yo) by a multiple bead array by the means of internally colour-codes microspheres with fluorescent dyes excited by laser beams. Statistical analysis performed with unpaired t-test.

Results: All pregnancies were uncomplicated and normal newborns delivered. The GDM group demonstrated significantly higher serum insulin levels than NGD ($12,06 \pm 1,7$ vs $7,28 \pm 0,94$ μ IU/ml) ($p=0,02$), while at the same euglycemic levels indicating the presence of insulin resistance state for GDM mothers. GHbA1c levels of GDM were within normal limits ($4,5 \pm 0,4\%$). There was no difference in the BMI of GDM vs NGD before pregnancy ($25,92 \pm 1,2$ vs $24,25 \pm 1,9$) as well as for the weight gained during pregnancy between the groups ($10,96 \pm 1,5$ vs $13,8 \pm 3,6$ kg). Circulating concentrations of both sVEGFR-1 ($2239,03 \pm 170,5$ vs $1746,24 \pm 36,8$ pg/ml) ($p<0,004$) and sVEGFR-2 ($6759,52 \pm 1071,5$ vs $1230,92 \pm 234,2$ pg/ml) ($p<0,0004$) were significantly increased in the GDM group than NGD.

Conclusion: Our results indicate that differences in the circulating levels of sVEGFR-1 and sVEGFR-2 are already present in the uncomplicated gestational diabetes in comparison to normal pregnancy and the monitoring of a further derangement in the profile of the pro-angiogenic and anti-angiogenic stability may be considered essential in the early detection of the progression to gestational abnormalities.

Women with previous gestational diabetes show impaired parameters one year before the onset of type 2 diabetes

A. Grassi^{1,2}, A. Tura¹, Y. Winhofer³, G. Pacini¹, A. Kautzky-Willer³;

¹Metabolic Unit, ISIB-CNR, Padova, ²Department of Information Engineering, University of Padova, Italy, ³Department of Internal Medicine III, Medical University of Vienna, Austria.

Background and aims: After delivery, women with previous gestational diabetes mellitus (pGDM), despite a frequent normalization of their glucose levels, are at increased risk of developing type 2 diabetes (T2D). For this reason, it is of paramount importance to assess whether there are indications in pGDM about their possible development of overt diabetes. Aim of this investigation was studying non-diabetic pGDM for 6 years after partum and identifying those parameters which may predict the onset of T2D one year before its occurrence.

Materials and methods: A total of 88 non-diabetic pGDM were studied with a 75g 2h-oral glucose tolerance test (OGTT) with measurements of glucose, insulin and C-peptide, immediately after partum and annually during the 6-year study period. Insulin sensitivity and beta cell function were analyzed through mathematical modeling that yields fasting (QUICKI) and dynamic (OGIS) insulin sensitivity indices, and beta cell sensitivity to glucose stimulus (BGS). If a subject was found T2D at any year, she did not undergo any further examination. In this study, we analyzed the main anthropometric and metabolic parameters of non-diabetic pGDM who became T2D (progressors, PR) one year before the transition, compared to those parameters of the women who remained non-diabetic (non progressors, NP).

Results: Only 14 women became T2D. One year before onset of diabetes, PR showed impaired parameters when compared (Wilcoxon rank-sum test) with NP (Table). PR were slightly older and with higher BMI. Glucose was markedly elevated in PR; insulin and C-peptide were also elevated. Insulin sensitivity and beta cell function were clearly reduced in PR, but this impairment was more manifest with BGS, than with QUICKI and OGIS.

Conclusion: 16% of pGDM became T2D within 6 years after partum. All anthropometric and metabolic parameters were impaired in PR one year before the onset of T2D, mostly those related to insulin secretion. This strongly recommends a thorough follow up analysis of parameters (especially glucose levels and beta cell function index) in women with pGDM in order to early prevent the development of diabetes.

Table	NP	PR	p-value
Age(years)	35.0±0.3	39.6±1.2	0.001
BMI (kg m ⁻²)	26.0±0.3	32.0±2.2	0.003

PS 110 Pregnancy: biomarkers and outcomes

1202

To establish trimester-specific reference ranges for glycated haemoglobin (HbA_{1c}) in pregnancy

C.M. O'Connor¹, P. O'Shea², L.A. Owens¹, L. Carmody¹, G. Avalos¹, L. Nestor¹, K. Lydon¹, F. Dunne¹;

¹Department of Endocrinology, National University of Ireland, ²Department of Clinical Biochemistry, University College Hospital, Galway, Ireland.

Background and aims: Diabetes in Pregnancy imposes additional risks to both mother and infant. These poor outcomes are considered to be primarily related to glycaemic control which is monitored longitudinally through pregnancy by means of HbA_{1c}. The correlation between HbA_{1c} levels with clinical outcomes emphasises the need to measure HbA_{1c} accurately, precisely and for data interpretation comparison to appropriately defined reference intervals. From July 1st 2010, the HbA_{1c} assay in Irish laboratories became fully metrologically traceable to the IFCC standard, permitting HbA_{1c} to be reported in IFCC units (mmol/mol) and derived DCCT/NGSP units (%) using the IFCC-DCCT/NGSP master equation (DCCT = Diabetes Control and Complications Trial, NGSP = National Glycohemoglobin standardisation program). The aim of this project is to establish trimester-specific reference ranges in pregnancy for IFCC standardised HbA_{1c} in non-diabetic Caucasian women. This will allow us to define the goal for HbA_{1c} during pregnancy complicated by diabetes.

Materials and methods: Following informed consent blood was collected from 234 pregnant and 36 age -matched controls into EDTA and Fluoride oxalate tubes for HbA_{1c}, haemoglobin and glucose measurement. Pregnancy trimester was defined as follows: T1 (up to 12 weeks), T2 (13 to 27 weeks), T3 (>28 weeks to term). The Menarini HA8160 automated haemoglobin (Hb) analyser was used to assay HbA_{1c}.

Results: Non-parametric analysis of the data was performed. The 95% IFCC HbA_{1c} (DCCT) reference interval for Controls (n=59) 29-37mmol/mol (4.8-5.5%), Trimester 1 (n=27) 36mmol/mol (4.6-5.4%), Trimester 2 (n=107) 25-35mmol/mol (4.4-5.4%) and Trimester 3 (n=110) 28-39 mmol/mol (4.7-5.7%). A statistically significant difference between the median HbA_{1c} concentration of the control and Trimester 2 subjects, p <0.0001 was determined (Mann-Whitney test).

Conclusion: As HbA_{1c} changes throughout pregnancy, trimester-specific HbA_{1c} reference intervals are required to manage diabetes in pregnancy appropriately.

Glycaemic control in post-pregnancy follow-up in type 1 diabetes women

K. Cyganek¹, A. Hebda-Szydło¹, J. Skupien², B. Kutra¹, I. Janas³, I. Kaim⁴, S. Borys³, M. Szopa¹, A. Reron⁴, M.T. Malecki¹;

¹Department of Metabolic Disease, Jagiellonian University, Medical College, Krakow, Poland, ²Section on Genetics and Epidemiology, Joslin Diabetes Center, Boston, USA, ³Department of Metabolic Disease, University Hospital, Krakow, ⁴Department of Obstetrics and Perinatology, Jagiellonian University, Medical College, Krakow, Poland.

Background and aims: Tight glycaemic control is essential during pregnancy complicated by type 1 diabetes mellitus (T1DM) in order to improve the prognosis for a mother and a child. Most diabetic women with T1DM are able to significantly lower their glucose levels during the pregnancy. However, very few data exists on their glycaemic control after the delivery. The purpose of this observational study was to assess glycaemic control in T1DM women after the pregnancy.

Materials and methods: We examined medical records of 345 consecutive singleton pregnancies in women with pregestational T1DM that received medical care in Department of Metabolic Diseases, Krakow, Poland between 1999 and 2010. We found 213 subjects that received an intensive diabetes management program during pregnancy and had at least one follow-up visit with HbA_{1c} measurement after the delivery. We analysed HbA_{1c} level in the 1st trimester (reflecting pre- and early pregnancy periods), the 3rd trimester, and the last post-pregnancy follow-up measurement (mean 8.6 months ±15.4 post delivery).

Results: Mean age of examined women was 27.7 years \pm 4.6, duration of T1DM 12.0 years \pm 7.9. The mean initial HbA1c level was 6.9 % \pm 1.3. We observed a significant improvement of HbA1c level that reached 5.7 % in the 3rd trimester (5.7 % \pm 0.7; $p < 0.000001$). At the post-pregnancy follow-up, we noticed a substantial rise of HbA1c (by 1.1%). This was significantly higher than in the last trimester ($p < 0.00001$) but not different from the initial value ($p = 0.1$). Subjects that after pregnancy were on continuous insulin infusion ($n = 82$) showed smaller rise than those on multiple daily injections ($n = 131$) (mean 6.4 % \pm 1.0 vs. 6.9 \pm 1.6; $p = 0.0038$, respectively). When we analyzed data from the follow-up earlier than 12 months (179 measurements) and after this cut-off point (34 measurements), we found no difference in the HbA1c values (6.65 vs 6.94; $p = 0.3$).

Conclusion: Concluding, in this largest so far clinical observation, T1DM women showed substantial post-pregnancy deterioration in glycemic control. This deterioration seems to depend on the treatment method.

Higher levels of Atrial Natriuretic Peptide (ANP) are present in early pregnancy in type 1 diabetic women developing preeclampsia

L. Ringholm^{1,2}, U. Pedersen-Bjergaard³, B. Thorsteinsson^{3,4}, F. Boomsma⁵, P. Damm^{2,4}, E.R. Mathiesen^{2,4};

¹Department of Endocrinology, Rigshospitalet University Hospital of Copenhagen, ²Center for Pregnant Women with Diabetes, Rigshospitalet University Hospital of Copenhagen, ³Endocrinology Section, Department of Cardiology and Endocrinology, Hillerød Hospital, ⁴Faculty of Health Sciences, University of Copenhagen, Denmark, ⁵Section of Vascular Pharmacology and Metabolism, Department of Internal Medicine, Erasmus Medical Center, Rotterdam, Netherlands.

Background and aims: Preeclampsia is characterized by abnormal vascular development, trophoblast invasion and placentation in early pregnancy. The vasoactive factors Atrial Natriuretic Peptide (ANP) and Brain Natriuretic Peptide (BNP) are synthesized in cardiac tissue and are markers of cardiac overload. Higher levels of ANP and BNP have been demonstrated in late pregnancy with preeclampsia. We investigated whether higher levels of ANP and BNP are present in early pregnancy in women with type 1 diabetes who subsequently develop preeclampsia.

Materials and methods: Observational study of 84 consecutive pregnant women with type 1 diabetes (median duration 15 years (range 1–32) and HbA_{1c} 6.7% (4.9–10.5) in early pregnancy). At 9, 14, 21, 27 and 33 weeks blood was sampled for measurements of ANP and BNP. HbA_{1c}, blood pressure and 24-hour urinary albumin excretion (UAE) were recorded. Based on UAE at inclusion, the women were classified as having normoalbuminuria (UAE <30 mg/24 hour), microalbuminuria (UAE 30–299 mg/24hour) or diabetic nephropathy (UAE \geq 300 mg/24 hour). Preeclampsia in women with normoalbuminuria or microalbuminuria was defined as blood pressure >140/90 mmHg and proteinuria \geq 300 mg/24 hour after 20 weeks. In women with diabetic nephropathy, the diagnosis was based on the same findings accompanied by a sudden increase of \geq 15% in systolic or diastolic blood pressure.

Results: Preeclampsia developed at median 34 (range 33–35) weeks in six women (7%) characterized by higher levels of ANP at 9 weeks (6.0 (1.6–7.8) pmol/l vs. 2.9 (0.7–7.8), normal range 3.6 \pm 1.4 pmol/l, $p = 0.02$), higher occurrence of diabetic retinopathy (100% vs. 55%, $p = 0.04$) and higher occurrence of diabetic nephropathy at 9 weeks (50% vs. 4%, $p = 0.004$) compared with women without development of preeclampsia. At 9 weeks, ANP levels were positively correlated with UAE (per 100 mg increase/24 hour, $r = 0.36$, $p = 0.0009$). BNP levels at 9 weeks were comparable between women with and without development of preeclampsia (5.1 (2.0–16.7) pmol/l vs. 3.6 (0.5–11.2), normal range 2.3 \pm 1.7 pmol/l, $p = 0.18$). Throughout pregnancy ANP levels were 34% higher ($p = 0.02$) in women with development of preeclampsia compared with women without development of preeclampsia whereas BNP levels were comparable between the two groups ($p = 0.26$).

Conclusion: In women with type 1 diabetes, higher ANP levels are present as early as at 9 weeks and in the remaining part of pregnancy in women with development of preeclampsia. This suggests that cardiac overload in pregnancy may play a role in the pathogenesis of preeclampsia.

1205

Incidence of thyroid dysfunction in pregnant women with type 1 diabetes mellitus living in iodine deficient area

V.I. Pankiv¹, O.S. Payenok², R.I. Petruniak³;

¹Preventive Endocrinology, Endocrinological Centre, Kyiv, ²Obstetrics and gynaecology, Medical University, L'viv, ³Obstetrics and gynaecology, Regional Hospital, Kolomyja, Ukraine.

Background and aims: The interaction between pregnancy, diabetes mellitus and thyroid disturbance needs a particular attention. The antithyroid antibodies are more frequent in pregnant women with type 1 diabetes mellitus (DM) than in normal pregnant women. Beside, an increased prevalence of subclinical thyroid dysfunction has been described in pregnant diabetic women. The aim of this study is to verify if women with type 1 DM have more probability than normal women to develop a thyroid pathology in pregnancy, in an area with sufficient iodine.

Materials and methods: Ninety-six consecutive pregnant women with type 1 diabetes with age 20–38 years, and 25 healthy women, with the same age. Patients were evaluated at the following time-intervals: 9–12 and 18–20 weeks' gestation, at delivery and six months after delivery. We evaluated whether the presence of thyroid peroxidase autoantibodies (anti-TPO) was associated with changes in thyroid function, metabolic control and pregnancy outcome. At 8, 14, 21, 27 and 33 weeks, the diabetic women self-monitored plasma glucose (SMPG) (8/day) for 3 days and had blood samplings obtained.

Results: No significant difference was observed between diabetic and normal women, for the values of TSH ($p < 0.2$), FT4 ($p < 0.7$), FT3 ($p < 0.6$). Instead a significant difference was found between the thyroid volume ($p < 0.04$), in the diabetic patients versus the normal women, at delivery and six months after delivery. Anti-TPO was detected in 31 (32%) of the pregnant diabetic women compared with two women (8%) in the healthy controls ($p = 0.015$). The presence of anti-TPO was associated with higher TSH at 8 ($p < 0.0001$) and 14 weeks ($p < 0.05$) and lower free T4 at 8 weeks ($p < 0.05$) compared with anti-TPO negative women. Twenty untreated anti-TPO positive women had higher TSH compared with untreated, anti-TPO negative women ($p < 0.05$), but comparable free T4. Sixteen women (17%) were treated for thyroid disorder during pregnancy. No differences were detected between the diabetic women with and without anti-TPO regarding HbA_{1c}, insulin dose, median SMPG or pregnancy outcome. The results of this study underline the importance of the screening of the thyroid function and morphology, in all the pregnant women and, particularly, in the diabetic patients, to find the presence of glandular alterations as early as possible.

Conclusion: Anti-TPO was present in one-third of pregnant women with type 1 diabetes and associated with slightly higher TSH, but not poorer glycaemic control or adverse birth outcome. A total of 17% of women with type 1 diabetes mellitus were treated for thyroid disorder during pregnancy.

Maternal glucose levels in early pregnancy and the risk of allergy in infancy: the mother child rhea cohort in Crete, Greece

L. Chatzi¹, E. Bagkeris¹, E. Fthenou¹, A. Papaioannou¹, M. Vassilaki¹, M. Karachaliou¹, A. Koutis¹, A. Pappas², M. Kogevinas³;

¹Department of Social Medicine, Heraklion, Greece, ²Diabetic Clinic, Heraklion, Greece, ³Centre for Research in Environmental Epidemiology (CREAL), Barcelona, Spain.

Background and aims: Prenatal maternal-fetal interactions and early-life programming might be associated with the development of asthma or allergic diseases. A number of studies suggest an association of childhood obesity with early manifestations of atopy, such as atopic eczema, and asthma. However the possible role of intrauterine exposure to hyperglycemia in the pathogenesis of allergic diseases in early childhood remains poorly understood. The purpose of this study was to examine the relation of maternal glucose and insulin levels in early pregnancy with the risk of atopic eczema, persistent wheezing, and diagnosis of allergy in early childhood.

Materials and methods: The mother-child "Rhea" study in Crete is a prospective cohort examining pregnant women (Greek and immigrants) residents at the prefecture of Heraklion that became pregnant during one year starting in February 2007 and initiated prenatal care before 15 weeks of gestation (mean: 12 weeks). Five hundred and seventy five pregnant women and their children were included in the analysis. Maternal fasting serum samples were collected at the time of the first major ultrasound (Mean: 12 weeks, SD: 1.5). Pregnant women were screened for gestational diabetes mellitus (GDM) between 24

and 28 weeks of gestation, and GDM was defined by the criteria proposed by Carpenter and Coustan. The primary outcome variables were physician-diagnosed atopic eczema, allergy, and persistent wheezing defined as two of more episodes of wheezing in the first year of life lasting more than three days. Multivariable log-binomial regression models were used after adjusting for the following confounders: offspring sex, birth weight, breastfeeding duration, maternal age, maternal education, parity, maternal pre-pregnancy BMI, parental asthma, and parental atopic eczema.

Results: Among the 575 children, 14.6% had been diagnosed with atopic dermatitis, 7.9% with allergy, and 7.9% with persistent wheezing in the first year of life. Overall, 8.1% of the mothers had GDM. An elevation of 10mg/dl in fasting glucose levels in early pregnancy increased the relative risk for atopic eczema by 28% (RR=1.28, 95 percent CI: 1.06, 1.55), while a 20mU/ml increase in fasting insulin levels increased the risk for atopic eczema by 14% (RR=1.14, 95 percent CI: 1.02, 1.28). Maternal glucose and insulin levels in early pregnancy showed no association with persistent wheezing in the first year of life. GDM was not found to be significantly associated with atopic dermatitis, allergy, or persistent wheezing in the first year of life.

Conclusion: These findings suggest that elevated glucose and insulin levels in early pregnancy increase the risk of atopic dermatitis in the first year of life. Further follow up of this cohort will allow determining if maternal hyperglycaemia has, an effect on asthma and allergy in later childhood.

The effect on clinician practices of the initiation of a new management programme for diabetes in pregnancy

W.B. Giles¹, C. Johnson², S. Buchanan¹, G. Fulcher³;

¹Obstetrics and Gynaecology, University of Sydney Northern Clinical

School, ²Obstetrics and Gynaecology, Royal North Shore Hospital,

³Endocrinology, University of Sydney Northern Clinical School, St Leonards, Australia.

Background and aims: Following initial assessment of outcomes for women in our unit when NICE and ADIPS guidelines were instituted (reported at EASD 2010) we assessed what change if any had occurred in clinician management.

Materials and methods: We reviewed and compared the actions of clinicians prior to (pre 2008 cohort) and after the institution of the above guidelines (2008–2009 cohort). This consisted of routine fetal heart rate (FHR) monitoring at 36 weeks and growth ultrasounds at 28, 32 and 36 weeks gestation; insulin requiring women with unstable control were delivered at 39 weeks and those with optimal control were delivered at 40 weeks; and women with diet controlled gestational diabetes mellitus (GDM) were delivered by 41 weeks. The latter were followed throughout pregnancy in a routine antenatal clinic with review by obstetricians, diabetes educators, and dieticians. From the OBSTETRIX database data were obtained from 7 October 2006 until 31 December 2009.

Results: There were a total of 601 women; 211 women (pre new guidelines) and 390 in 2008–2009 (post new guidelines). The significant difference was that those women with insulin-controlled diabetes in pregnancy had a later gestation at delivery (P=0.036) showing that clinicians were undertaking a more conservative approach to induction of labour (IOL) in this group of women. There was a trend to a reduction in rates of IOL between the two groups 57% vs. 44% but this did not reach significance (P=0.059) and a trend to reduction in instrumental deliveries (P=0.055). As noted in our previous report the majority of women in the second cohort laboured spontaneously. There were no differences between the two groups in birth weights >4000g; or rates of shoulder dystocia, caesarean section, instrumental delivery, admissions to the nursery (NICU and SCN) and Apgar scores ≤7 between the two cohorts.

Conclusion: The institution of the newer guidelines resulted in later delivery and IOL in the women requiring insulin. There were no increases in adverse outcomes with the change of management.

1208

Maternal glycaemic control and hypoglycaemia in pregnancy: a randomised trial comparing insulin detemir with NPH insulin in 310 subjects with type 1 diabetes

E.R. Mathiesen¹, P. Damm¹, M. Hod², D.R. McCance³, M. Ivanisevic⁴, S. Garcia⁵, L. Jovanovic⁶;

¹Department of Endocrinology 2-13-2, Rigshospitalet, Copenhagen, Denmark, ²Rabin Medical Center, Tel-Aviv, Israel, ³Metabolic Unit, Belfast, UK, ⁴Department of Obstetrics and Gynaecology, Zagreb, Croatia, ⁵Catedra De Endocrinologia, Seville, Spain, ⁶Sansum Diabetes Research Institute, Santa Barbara, USA.

Background and aims: Rigorous data investigating basal insulin analogues in diabetic pregnancy are lacking. The aim of this prospective, randomised, controlled, parallel-group, open-label trial was to compare the efficacy and safety of insulin detemir (IDet) vs. NPH (both with prandial insulin aspart) in pregnant women with type 1 diabetes (T1DM).

Materials and methods: T1DM women (HbA1c ≤8 % at pregnancy confirmation) were randomised to IDet (n=152) or NPH (n=158) up to 12 months before pregnancy or during pregnancy at 8–12 weeks gestation. The primary objective was to show that IDet was non-inferior to NPH for HbA1c at 36 gestational weeks (GWs) (primary endpoint). Non-inferiority was shown if the upper limit of the 95% CI for the treatment difference of IDet vs. NPH was below the pre-specified non-inferiority margin of 0.4% for both the Full Analysis Set (FAS) and Per Protocol Set (PP). The data were analysed using linear regression with effects of treatment, country and pregnancy status at randomisation, HbA1c at randomisation and the HbA1c at randomisation by pregnancy status at randomisation interaction.

Results: 79 and 83 women in the IDet and NPH groups, respectively, were pregnant at randomisation while 73 and 75 women, respectively, became pregnant following randomisation. Mean±SD demographics were: age 30.1±4.4 yrs; BMI 24.8±4.1 kg/m²; HbA1c 7.01±0.79%; fasting plasma glucose (FPG) 5.94±3.25 mmol/l and diabetes duration 12.3±8.0 yrs. For FAS, the estimated HbA1c at GW36 was 6.27% for IDet and 6.33% for NPH. IDet was shown to be non-inferior to NPH and not superior (FAS: -0.06, 95% CI: -0.21; 0.08; PP: -0.151; 95% CI: -0.34; 0.04). Patients reaching HbA1c ≤6.0% at both GW 24 + 36 was higher with IDet (36%) vs. NPH (29%), p=NS. Estimated FPG was significantly lower with IDet vs. NPH at GW 24 (5.38 vs. 6.32 mmol/l, difference -0.94 [-1.67; -0.21], p=0.012) and at GW 36 (4.76 vs. 5.41 mmol/l, difference -0.65 [-1.19; -0.12], p=0.017). There were no statistically significant or clinically relevant differences in hypoglycaemic events between treatments. The rate of major hypoglycaemia (events/yr) was 1.1 for IDet vs. 1.2 for NPH. There was no difference between groups in weight gain during pregnancy (11.5 kg and 11.0 kg, respectively). Mean doses of basal and bolus insulin increased during the 2nd and 3rd trimester and decreased after pregnancy, with no differences between treatments.

Conclusion: Lower FPG, but comparable HbA1c in late pregnancy was obtained using insulin detemir in comparison to NPH insulin in women with type 1 diabetes. Figure. Mean±SD HbA1c during pregnancy by timing of randomisation. D=delivery; 6WPP=6-weeks postpartum.

Perinatal outcomes in pregnancy: a randomised trial comparing insulin detemir with NPH insulin in 310 subjects with type 1 diabetes

M. Hod¹, D.R. McCance², M. Ivanisevic³, S. Garcia⁴, L. Jovanovic⁵, E.R. Mathiesen⁶, P. Damm⁶

¹Division of Maternal Fetal Medicine, Helen Schneider Hospital for Women, Tel-Aviv, Israel, ²Metabolic Unit, Royal Victoria Hospital, Belfast, UK,

³Department of Obstetrics and Gynaecology, Zagreb, Croatia, ⁴Catedra De Endocrinologia, Seville, Spain, ⁵Sansum Diabetes Research Institute, Santa Barbara, USA, ⁶Rigshospitalet, Copenhagen, Denmark.

Background and aims: The use of long-acting insulin analogues before and during pregnancy in type 1 diabetes is increasing, but their efficacy and safety remains uncertain. The aim of this prospective, randomised, controlled, par-

allel-group, open-label trial was to compare the efficacy and safety of insulin detemir (IDet) vs. NPH insulin (both with mealtime insulin aspart) in pregnant women with type 1 diabetes.

Materials and methods: Pregnant women with type 1 diabetes (age ≥ 18 yrs, HbA_{1c} $\leq 8\%$ at pregnancy confirmation) were randomised to IDet (n=152) or NPH (n=158) either before (up to 12 months) pregnancy (n=148) or during pregnancy (8–12 weeks gestation) (n=162). Pregnancy outcomes included a composite endpoint comprising: live born infants with birth weight $<10^{\text{th}}$ or $>90^{\text{th}}$ percentile for gestational age (GA) and sex; preterm delivery (<37 gestational weeks (GWs)); early fetal demise (<22 GWs); perinatal mortality; neonatal mortality; presence of major congenital malformations. Other endpoints included: live born infants; neonatal hypoglycaemia (PG <1.7 mmol/l within 24 hours of delivery); and adverse events (AEs) in offspring. The data were analysed using logistic analysis with treatment and pregnancy status at randomisation as covariates.

Results: There were 152 and 160 pregnancies in the IDet and NPH groups, respectively (2 women in the NPH group had a miscarriage and became pregnant again, without withdrawing). 25 pregnant women withdrew from the trial (10 in the IDet group vs. 15 in the NPH group); therefore pregnancy outcome is reported for 142 and 145 women, respectively. 89 (62.7%) of IDet vs. 96 (66.2%) of NPH-treated subjects experienced at least one endpoint in the composite outcome (odds ratio (OR) IDet/NPH: 0.86 [95% CI 0.53; 1.40], $p=0.551$). Maternal and neonatal outcomes for live born children were similar between the two groups (Table). 17 children (8 IDet/9 NPH) had congenital malformations. There were 2 perinatal deaths in the IDet group and 1 in the NPH group. 15 vs. 24 children in the IDet and NPH groups, respectively, experienced neonatal hypoglycaemia within 24 hours of delivery. There was no difference in the incidence of adverse events in the offspring between the two groups (37% IDet/35% NPH) or in the number of AEs/child (IDet 2.2/ NPH 2.7).

Conclusion: IDet is as well-tolerated as NPH with respect to perinatal morbidity and mortality when administered during pregnancy to subjects with type 1 diabetes.

Pregnancy assessments for live born children.

A meta-analysis of maternal outcomes in pregnant women using insulin glargine compared with NPH insulin

J. Lin¹, J. Lepercq², G. Hall³, M.-P. Dain⁴, M.C. Riddle⁵, P.D. Home⁶;

¹Novosys Health, Flemington, USA, ²Cochin Saint Vincent de Paul, Paris,

France, ³Grimsdyke House, London, UK, ⁴sanofi-aventis, Paris, France,

⁵Oregon Health and Science University, Portland, USA, ⁶Newcastle University, UK.

Background and aims: Studies of insulin glargine in pregnancy are of small numbers of women. We aimed to provide quantitative estimates of maternal outcomes in women treated with insulin glargine versus NPH insulin during pregnancy.

Materials and methods: A literature search from multiple sources identified 49 articles related to insulin glargine and pregnancy. Eight articles that reported results of observational studies of diabetes pregnancies (preexisting or gestational diabetes) on at least 15 women each on insulin glargine and NPH insulin were included in the meta-analysis. Data from these studies were extracted and synthesized using methodology recommended by Cochrane Reviews with the software tool Review Manager 5.0. Mantel-Haenszel odds ratios were determined for all dichotomous outcome data using a random

effect model. Mean differences were determined for all continuous outcome data using an inverse variance method with a random effect model.

Results: The studies comprised a total of 702 women treated with either insulin glargine ($n = 331$) or NPH insulin ($n = 371$). Mean maternal age, body weight and body mass index were not different between the two groups of women using insulin glargine or NPH insulin. Women taking insulin glargine had diabetes 1.1 year (95% CI: 0.3, 2.0) longer than women taking NPH insulin. Maternal outcome measures including weight at delivery, weight gain, first and third trimester HbA_{1c} and incidence of hypoglycaemia, preeclampsia, cesarean section and gestational / new-onset hypertension were not different for insulin glargine versus NPH insulin (Table).

Conclusion: Published studies of insulin glargine versus NPH insulin in pregnancy give no signal of concern for insulin glargine regarding the maternal outcome measures evaluated. However, because quantitative estimates of difference for individual measures have large uncertainties, accumulation of larger data sets is now warranted. Close monitoring during pregnancy and just after birth is highly recommended for women with diabetes who are taking insulin.

Mean of differences across studies (insulin glargine - NPH insulin)				
Outcome	Studies/ Women (n/n)	Mean difference*	Odds ratio	95% CI
Weight at delivery (kg)	4/346	-0.82	—	-6.79, 5.15
Weight gain (kg)	5/495	0.16	—	-1.03, 1.35
HbA _{1c} - first trimester (%)	4/301	-0.08	—	-0.64, 0.49
HbA _{1c} - third trimester (%)	6/538	-0.01	—	-0.07, 0.05
Maternal hypoglycaemia - severe	5/472	—	0.84	0.18, 3.79
Pre-eclampsia	8/702	—	0.55	0.23, 1.32
Cesarean section	6/608	—	1.04	0.72, 1.52

Visual evoked potentials and psychomotor outcome in children of type 1 diabetic mothers, 3 years after delivery

A. Napoli¹, M. Brinciotti², M. Matricardi², G. Merola¹, O. Bitterman¹, A. Mittica¹,

¹Clinical and molecular sciences, ²Pediatrics and Child Neuropsychiatry, "Sapienza" University of Rome, Italy.

Background: The exposure to diabetic environment during pregnancy may have negative effects on brain functions of the offspring. Evoked potentials are sensitive indexes of central nervous system function.

Aim: to analyze maturation of Visual Evoked Potentials (VEPs) and psychomotor development during the first 3 years of life in Infants of type-1 Diabetic Mothers (IDMs).

Materials and methods: VEPs and psychomotor development were assessed serially between 2 months and 3 years of age in 16 IDMs (11 females, 5 males). Latency and amplitude of VEPs were compared with data obtained from a matched control group of 23 healthy children of non-diabetic mothers. VEP recording: 1. Binocular stimulation (white light, intensity 0,3 Joule, repetition rate 2 Hz). 2. Responses were recorded according to the American Electroencephalographic Society guidelines with a bandpass of 1-100 Hz. At least two trials of 100 artefact-free responses were recorded within 512 ms after stimulus. 3. Peak latencies and peak-to-peak amplitudes of all components were measured but only the most stable components (III, IV, V) were used for statistical comparisons. Psychomotor development test: Brunet-Lézine. Statistical analysis: ANOVA, non parametric tests and χ^2 with Yates correction when appropriate.

Results: All IDMs had normal outcome of global psychomotor development (IQ > 80). At the age of two months, IDMs showed mean latency of all VEP components significantly delayed compared with controls (right: latency of the forth component $199 \pm 32,8$ vs $155,6 \pm 29,0$ of controls [P 0,001]; left: latency of the forth component $194,7 \pm 35,74$ vs $155,3 \pm 30,3$ of controls [P 0,001]). At the end of follow-up, the latency of the forth (P2) component was still delayed compared with controls (right: $105,53 \pm 13,1$ vs $99,96 \pm 8,8$ of

controls [P 0,001]; left: $106,13 \pm 14,0$ vs $98,69 \pm 10,2$ of controls [P 0,001]). Abnormal VEPs (latency + 3 SD from normal mean value) were found in 2 cases (13%).

Conclusion: During the first 3 years of life, children of diabetic mothers had a normal outcome of global psychomotor development, but their VEPs showed a delayed maturation with mean P2 latency slower than controls, and abnormal responses in some cases. In these children, evoked potentials seem to be particularly sensitive tool to evidence subtle functional abnormalities of the central nervous system.

Glyoxalase I knock down in human aortic endothelial cells: a proteomic based approach

T. Gawłowski^{1,2}, B. Engelbrecht¹, D. Tschoepe¹, G. Poschmann³, K. Stuehler³, B. Stratmann¹;

¹Heart- and Diabetes Center NRW, Bad Oeynhausen, Germany,

²Department of Medicine, University of California, San Diego, USA,

³Medizinisches Proteom-Center, Bochum, Germany.

Background and aims: Hyperglycemia plays an important role in the pathogenesis of diabetic complications including accumulation of methylglyoxal (MG), a highly reactive α -oxoaldehyde that is formed in cells primarily from the triose phosphate intermediates of glycolysis, dihydroxyacetone phosphate and glyceraldehyde 3-phosphate and increased generation of advanced glycation endproducts (AGEs). The principal targets of MG modification are arginine residues of proteins. Reaction of MG with arginine in a non-enzymatic reaction leads to the formation of AGEs such as argpyrimidine and hydroimidazolone. Furthermore, MG is involved in regulation of different genes by modification of distinct transcription factors like mSin3A and Yap1. Glyoxalase 1 (GLO1), together with glyoxalase 2 and the co-factor glutathione, constitute the glyoxalase system, which is responsible for the detoxification of MG. A GLO1 specific knock down results in accumulation of MG in cells. **Methods:** The human aortic endothelial cells (HAEC) were transfected with GLO1-specific siRNA and cultured under hyperglycemic conditions (25 mM glucose). In order to achieve a better understanding of MG regulated gene expression 2D-DiGE proteomics technique was used to examine the changes in protein expression induced in HAEC by GLO1 knock down. Moreover, we investigated the effects of the knock down on apoptosis and oxidative stress by flow cytometry.

Results: GLO1-RNA was significantly downregulated about 90 % in these experiments if compared to siRNA-control. Proteomics analysis identified targets being significantly downregulated by intracellular MG accumulation, which can be grouped according to function: RNA stability and translation: HNRNPA1 (fold change (FC)=1.49) and EF1alpha (FC=1.43). Procollagen hydroxylation: LEPREL-2 (FC=1.40) and PLOD-2 (FC=1.43). Cytoskeleton and intermediate filaments: Vimentin (FC=2.11) and Lamin A/C (FC=1.74). There was a trend to down-regulation of GAPDH and malatdehydrogenase. Regarding oxidative stress there was no significant increase compared to the control transfection with non-specific, scrambled siRNA. Apoptosis was significantly increased under these conditions (161 %, compared to siRNA-control).

Conclusion: Several proteins have been identified as being regulated under hyperglycemic conditions in combination with a GLO1 knock down. The effect of MG accumulation is of concern regarding biosynthesis, posttranslational modification and structural stabilization. These modifications could at least explain the proapoptotic trend of the cells. Further evaluation and verification of these findings is needed to elucidate the effect of MG as a proapoptotic compound.

Endogenous hydrogen sulphide (H₂S) and novel slow release H₂S donors protect human microvascular endothelial cells from oxidative stress-induced cell death

S. Le Trionnaire¹, J. Whatmore¹, A. Perry², M.E. Wood², M. Whiteman¹;

¹University of Exeter, Peninsula Medical School, ²Biosciences, University of Exeter, UK.

Background and aims: Significant microvascular endothelial dysfunction (MED) is observed in patients with type II diabetes mellitus (T2DM). However, the underlying mechanisms for this phenomenon are not fully understood but may involve oxidative / glycoxidative, increased production of cytotoxic lipid peroxides and glycation agents and mitochondrial toxicity. Recently we showed that lower levels of the endothelium-dependent endogenous gaseous vasodilator hydrogen sulfide (H₂S) in overweight and T2DM subjects compared to age-matched controls and that plasma H₂S levels were strongly negatively correlated with impaired microvascular function, insulin sensitivity and glycaemic control *in vivo*. H₂S is synthesised in humans from L-cysteine by the pyridoxal phosphate-dependent enzymes cystathionine-

beta-synthase (CBS) and cystathionine-gamma-lyase (CSE). Since H₂S is known to 'scavenge' oxidant species detrimental to the vasculature *in vitro* we aimed to determine whether endogenous H₂S and novel slow release H₂S donor molecules (SRHD) could prevent or reverse oxidative stress-induced MED.

Materials and methods: Human microvascular endothelial cells (HMEC) were exposed to oxidative stress inducing agents (SIN-1, a peroxynitrite donor), hydrogen peroxide, the lipid peroxidation product 4-hydroxynonenal (4-HNE) and the glycoxidation product methylglyoxal (MG). Cell viability was determined by alamar blue assay and mitochondrial membrane potential ($\Delta\Psi_m$) determined using tetramethylrhodamine methyl ester (TMRM). Endogenous H₂S synthesis was inhibited using D,L-propargylglycine (PAG; to inhibit CSE) and aminooxyacetate (AOAA; to inhibit CBS). Pharmacological H₂S was generated using GYY41317, MC0510 and MC0610; novel slow release donors which model CSE/CBS-derived H₂S synthesis.

Results: SIN-1 (20–500 μ M), 4-HNE (1–20 μ M) and MG (20–200 μ M) induced significant concentration-dependent reduction in cell viability (each $p < 0.01$, ANOVA post hoc Dunnett's test). Concentrations of SIN-1, 4-HNE and MG of 100 μ M, 10 μ M and 100 μ M were used for further studies. Incubation of cells with H₂S synthesis inhibitors PAG (1 mM) and AOAA (1 mM) for 1 hour prior to induction of oxidative stress significantly increased SIN-1, MG and 4-HNE induced cell death (each $p < 0.01$ c.f. oxidant treatment alone) and loss of mitochondrial $\Delta\Psi_m$. In sharp contrast, treatment of HMEC with SRHD (100–500 μ M) significantly preserved mitochondrial $\Delta\Psi_m$ and inhibited oxidant induced cell death.

Conclusion: Our study shows slow release H₂S donors can inhibit and reverse oxidative stress mediated cell injury. Strategies which increase vascular H₂S bioavailability may represent a novel therapeutic strategy to limit micro (and macro)vascular endothelial dysfunction in subjects with pre-diabetes and diabetes and maintain vascular health.

Oleic acid increases VEGF synthesis and secretion in aortic vascular smooth muscle cells via PI3-K and MAPK pathways: interplay with insulin and insulin resistance

G. Doronzo, M. Viretto, I. Russo, L. Mattiello, L. Di Martino, G. Anfossi, M. Trovati;

Department of Clinical and Biological Sciences, Internal Medicine and Metabolic Disease Unit, San Luigi Gonzaga Faculty of Medicine, San Luigi Gonzaga Hospital, Orbassano-Turin, Italy.

Background and aims: It is known that Free Fatty Acids (FFA) are not only energetic fuels, but also molecules able to induce insulin resistance by inhibiting the insulin signalling at different steps. They circulating concentrations are increased in obesity. The interplay among FFA, insulin and insulin-resistance in Vascular Smooth Muscle Cells (VSMC) are not fully clarified as yet. In other cell types, FFA increase the synthesis of Vascular Endothelial Growth Factor (VEGF), a molecule involved in mechanisms of vascular damage (such as instabilization of the atherosclerotic plaque) and of vascular repair (such as collateral vessel formation). Studies of our laboratory demonstrated that in VSMC insulin increases the synthesis of VEGF via PI3-K and MAPK signalling pathways, a phenomenon impaired in insulin resistant states. Aim of this study is to evaluate in VSMC: i) whether oleic acid induces synthesis/secretion of VEGF and interferes with the insulin action on the same phenomenon; ii) the signalling molecules involved; iii) whether these putative effects of oleic acid are modified by insulin resistance.

Materials and methods: The study has been carried out in VSMC obtained as primary culture in our laboratory from aortas of insulin sensitive lean Zucker rats and insulin resistant obese Zucker rats. We measured the influence of a 24-hour incubation with 50–100 microM oleic acid and/or with 2 nM insulin on VEGF protein synthesis and secretion (western immunoblotting and ELISA) (n=6). To evaluate the signalling molecules involved, the experiments were repeated after 60 min pre-incubation with: i) LY294002 (50 microM) and wortmannin (100 nM), specific PI3-K inhibitors; ii) rapamycin (100 nM), a specific inhibitor of mTOR, a molecule activated also by Akt; iii) specific inhibitors of molecules of the MAPK pathway: a) PD98059 (30 microM), inhibitor of ERK-1/2; b) SP600125 (15 microM), inhibitor of JNK-1/2; c) SB203580 (10 microM), inhibitor of p38 MAPK. Results are expressed as mean \pm SEM.

Results: In aortic VSMC from lean insulin sensitive Zucker rats: i) oleic acid 50–100 microM dose-dependently increased VEGF synthesis and secretion ($p=0.003$ – 0.0001); ii) oleic acid did not modify the ability of insulin to in-

crease VEGF synthesis and secretion. Furthermore, in these cells the effects of oleic acid on both synthesis and secretion of VEGF: a) are mediated by PI3K/Akt-pathway activation, being blunted by LY294002 and wortmannin ($p=0.04$ – 0.0001), but without an involvement of mTOR, being unaffected by rapamycin; b) are mediated by ERK-1/2 and JNK 1/2 activation, being blunted by PD98059 and SP600125 ($p=0.05$ – 0.027), but without an involvement of p38MAPK, being unaffected by SB203580. In aortic VSMC from obese Zucker rats oleic acid did not increase synthesis and secretion of VEGF.

Conclusion: Oleic acid increases VEGF synthesis and secretion in aortic VSMC from lean, insulin-sensitive Zucker rats with a mechanism mediated by molecules of PI3-K/Akt and of MAPK pathways, without interfering with the similar action exerted by insulin. These effects are lost in aortic VSMC from obese, insulin resistant Zucker rats, that are therefore resistant to both insulin and oleic acid as far as VEGF synthesis and secretion is concerned.

Background and aims: Impaired endothelium-mediated vasodilation has been described in diabetic patients, suggesting decreased NO availability. However, a hyperglycaemia induced decrease in endothelial Nitric Oxide Synthase (eNOS) expression and activity is far from being firmly demonstrated. Indeed, hyperglycaemia increases superoxide anion (O_2^-) production: this might actually increase eNOS expression and activity, but divert Nitric Oxide (NO) to the formation of peroxynitrite ($ONOO^-$) and then nitrotyrosine (NT) within the vascular wall, thus inducing vascular damage and reducing NO bioavailability. Aim of the present study was to determine whether in the umbilical cord vessels and endothelial cells obtained from women with gestational diabetes (and thus with chronically elevated blood glucose levels) increased NT and eNOS levels were present and to investigate whether eNOS uncoupling and changes in NO bioavailability occur in these conditions.

Materials and methods: Tissue specimens and cultured human umbilical vein endothelial cells (HUVEC) were obtained from umbilical cords of 10 healthy women (Control, C) and 10 women with Gestational Diabetes (GD). Vascular NT and eNOS protein levels were evaluated in cord tissues (immunohistochemistry); NT and O_2^- levels (immunofluorescence), eNOS mRNA and protein (ratio of eNOS monomers to dimers) levels (Real-Time PCR and Western Blot), eNOS activity (conversion of [3H]-L-arginine in [3H]-L-citrulline) and cGMP production (ELISA) were measured in C- and GD-HUVEC.

Results: As compared to the proper controls, NT levels were significantly increased both in GD umbilical cords (25.90 ± 2.02 vs 11.70 ± 7.47 , $p < 0.05$ at MetaMorph Analysis System quantitation) and in GD-HUVEC (0.048 ± 0.003 vs 0.039 ± 0.003 AU, $p < 0.05$). As expected, GD cells showed markedly increased O_2^- production. eNOS expression resulted two-fold increased both in GD tissue specimens (39.04 ± 12.12 vs 17.29 ± 13.24 , $p < 0.003$) and in GD-HUVEC (eNOS/GAPDH mRNA = 1.0 ± 0.1 vs 0.6 ± 0.05 ; eNOS protein 0.64 ± 0.09 vs 0.37 ± 0.01 AU) but with a comparable ratio eNOS monomers/dimers in C and GD samples. Increased NOS activity was observed in GD-HUVEC (0.20 ± 0.02 vs 0.12 ± 0.03 pmol/mg protein⁻¹/min⁻¹, $p < 0.05$) which however was not paralleled by an increase in cGMP production, a natural target of NO activity (18.1 ± 4.24 vs 22.04 ± 5.61 fmol/ml).

Conclusion: Our data indicate that in presence of chronic hyperglycaemia endothelium from GD umbilical cords is characterized by increased NT production driven by increased O_2^- and NO generation. These data further indicate that hyperglycaemia, by increasing O_2^- levels, decreases vascular NO availability via NO consumption rather than through eNOS uncoupling, thus contributing to endothelial dysfunction in diabetes.

Angiotensin II type 1 receptor, but not type 2, interferes with the insulin-induced nitric oxide production in HUVECs

F. Andreozzi, I. Presta, E.J. Tassone, G.C. Mannino, S. Di Cello, A. Sciacqua, G. Sesti, F. Perticone;
Department of Experimental and Clinical Medicine, University of Catanzaro, Italy.

Background and aims: Angiotensin II (ATII) is a bioactive peptide of the renin-angiotensin-aldosterone system that plays an important role in the regulation of cardiovascular system and in the development of cardiovascular diseases. ATII exerts its different biological activities by binding to one of two known and well characterized receptor types, AT₁R and AT₂R. Despite the fact that these receptors share a similar high affinity to ATII, the consequences of their binding are opposite. AT₁R mediates ATII-induced vasoconstriction, cellular proliferation, inflammation and extracellular matrix remodelling. Conversely, AT₂R provides a protective role promoting vasodilatation, anti-proliferative and anti-inflammatory effects. We demonstrated that ATII impairs insulin signaling involved in nitric oxide (NO) production through IRS1/PI3K/Akt/eNOS pathway. In particular, the uncoupling of IRS1 and PI3K in ATII-treated endothelial cells may be linked to an increased phosphorylation at Ser³¹² and Ser⁶¹⁶ of IRS1, mediated by JNK and ERK 1/2, respectively. These changes are associated with a concomitant reduction in phosphorylation of Tyr⁶¹² and Tyr⁶³², resulting in an impaired activation of IRS1/Akt/eNOS pathway. All these effects occurred via the AT₁R stimulation, as deduced by the ability of the selective AT₁R antagonist, losartan, to revert the inhibitory effect of ATII. It has been proposed that the beneficial effects related to the use of AT₁R blockers is due also to the stimulation of AT₂R resulting from AT₁R blockage. The aim of this study was to investigate in HUVECs the effect of AT₂R blockage, evaluating whether the AT₂R is directly involved in the ATII effects on insulin signaling leading to NO production.

Materials and methods: HUVECs were incubated with ATII (100 nmol/l), AT₁R and AT₂R inhibitors (losartan 200nmol/l and PD123319 2mmol/l), alone or in combination, in the presence or absence of insulin (100 nmol/l). eNOS Activity Assay kit was used to measure eNOS activity.

Results: Exposure of HUVECs to ATII resulted in a time-dependent increase in IRS1 phosphorylation at both Ser³¹² and Ser⁶¹⁶, and in a parallel increase in phosphorylation of JNK and ERK1/2. Insulin increased by 2.7 fold ($p < 0.02$) the binding of IRS1 to the p85 subunit, while ATII treatment reduced this binding by 55%. ATII treatment resulted also in 55% inhibition of insulin-stimulated tyrosine phosphorylation of IRS1 in comparison with insulin alone ($p < 0.01$). Insulin increased by 3.5 fold ($p < 0.01$) the Ser⁴⁷³ Akt phosphorylation and by 2.6 fold ($p < 0.02$) the phosphorylation of eNOS on Ser¹¹⁷⁷, while ATII treatment reduced it by 56% and 62% ($p < 0.01$) respectively. eNOS activity was increased 2.5 fold ($p < 0.01$) by insulin, while it was inhibited by ATII ($p < 0.02$). Treatment of HUVECs with losartan reversed the inhibitory effects of ATII on insulin sensitivity, while no effects were observed with the PD123319. Furthermore, the simultaneous incubation with both inhibitors did not change the stimulatory effects of insulin as compared with losartan alone.

Conclusion: Our data extend the previous knowledge about the role of AT₁R and AT₂R on insulin signalling pathway. On the basis of these evidences, it is realistic to propose that the biological and protective effects typical of ATII receptor blockers are exclusively induced by the specific inhibition of AT₁R and not by the stimulation of AT₂R.

Signal crosstalk between S1P and angiotensin II in human microvascular endothelial cells: participation of GAP proteins

K. Sarai, K. Shikata, K. Omori, Y. Shikata, N. Watanabe, R. Kodera, J. Wada, H. Makino;
Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine, Japan.

Background and aims: Sphingosine 1-phosphate (S1P) is a biologically active lipid generated by membrane lipids in activated platelets. S1P organizes actin into a strong cortical ring and strengthens both intercellular and cell-matrix adherens. S1P (500nM) induced small GTPase Rac activation and stimulated the phosphorylation of focal adhesion kinase (FAK) Y⁵⁷⁶, and FA (Focal Adhesion) proteins (FAK and paxillin) were linked to FA redistribution to the cell periphery. These effects are linked to S1P-induced endothelial barrier enhancement. Angiotensin II (AII) is a key molecule in the progression of

diabetic complications leading to endothelial dysfunction, cellular proliferation and inflammation. AII is known to induce actin-containing stress fiber formation and small GTPase Rho activation, involved in the process leading to endothelial barrier dysfunction. We have reported S1P-analog induced redistribution of FA proteins and regulation of Rac/Rho activity. Considering the opposite role of Rac/Rho in endothelial barrier regulation, S1P may ameliorate AII-induced endothelial barrier dysfunction, one of the important mechanisms underlying diabetic angiopathy. Small G proteins cycle between a GTP-bound “on” state and a GDP-bound “off” state are negatively regulated by GTPase-activating proteins (GAPs), which accelerate the small GTPase’s intrinsic hydrolysis of bound GTP to GDP. RhoGAPs thus act as an inhibitor of Rho activation. If there exists a signal crosstalk between S1P and AII, RhoGAPs may be involved in the regulation of small GTPase activity.

Materials and methods: Quiescent human microvascular endothelial cells (HMVECs) were stimulated with AII (100nM, 10min.) and / or S1P (30min.). 1) To monitor FA proteins and actin redistribution, immunofluorescent microscopies were performed. 2) To investigate the signal crosstalk between S1P and AII, Rac and Rho activity assay and RhoGAP activity assay was performed.

Results: 1) Immunofluorescent microscopy revealed that actin-containing stress fibers and FAs redistribution were observed under AII stimulated condition. On the other hand, the cells pre-treated with AII were mimicked actin and FA proteins redistribution by post-treatment with S1P as observed stimulation of S1P only. Contrary, AII reorganized the S1P-induced cortical distribution of actin and FA proteins into stress fibers and newly formed FAs, respectively. The distribution of AJ proteins also suggested counter effects between AII and S1P on AJ assembly. 2) Rac activity assay and Rho activity assay revealed S1P induced Rac activation and this activity returned to the basal level after AII treatment, whereas S1P restored AII-stimulated Rho activity to the basal level. RhoGAP assay revealed AII decreased RhoGAP activation. S1P stimulated RhoGAP activation in both AII-treated and non-treated cells. Elevated RhoGAP activity returned to the basal level by AII.

Conclusion: In this study, S1P revealed the protective effects against AII stimulated condition. S1P also restored elevated Rho activation by AII pre-treatment. S1P induced activation of RhoGAP. Our results strongly suggest signal crosstalk between S1P and AII in the regulation of small GTPase activity. RhoGAPs may at least partially participate in this process involving in endothelial barrier regulation, suggesting the possible role of S1P to ameliorate AII-induced vascular disorder.

SLC24A6 is involved in high glucose-induced endothelial cell apoptosis via regulating intracellular calcium concentration

X. Wang¹, Y. Liu², Z. Yang¹, Z. Zhang¹, W. Zhou¹, R. Hu¹

¹Department of Endocrinology, Huashan Hospital, Fudan University, Shanghai, ²Department of Geriatric Endocrinology, General Hospital of PLA, Beijing, China.

Background and aims: Endothelial dysfunction contributes to the pathogenesis of vascular diseases in diabetics. Several lines of evidence has indicated that high glucose-induced apoptosis of endothelial cells plays important roles in the pathogenesis of endothelial dysfunction. However, the underlying mechanisms by which high glucose initiates apoptosis in endothelial cells have not been fully elucidated. In the present study, we investigated the roles and possible mechanisms of a Na⁺/Ca²⁺ exchanger, SLC24A6, in high glucose-induced apoptosis in endothelial cells.

Materials and methods: Lentivirus containing full-length cDNA of human SLC24A6 (Lenti-SLC24A6) and small interfering RNA designed for human SLC24A6 (SLC24A6 siRNA) were generated. After human aortic endothelial cells (HAEC) were transfected with Lenti-SLC24A6 or SLC24A6 siRNA, cell apoptosis was evaluated by DNA fragmentation analysis, the intracellular Ca²⁺ concentration ([Ca²⁺]_i) of HAEC was determined by using Fura-2 ratio technique, calcineurin phosphatase activity was measured using Calcineurin Cellular Activity Assay Kit, and phosphorylated BAD (phospho-BAD) was investigated by western blotting. HAEC were cultured with 30 mmol/L (high glucose) or 5.6 mmol/L glucose (low glucose) for 96 h, and then SLC24A6 expression was detected by western blotting. Cell apoptosis, [Ca²⁺]_i, calcineurin phosphatase activity, and phospho-BAD were also investigated in glucose-treated HAEC. Meanwhile, the impacts of high glucose on cell apoptosis were evaluated after HAEC were transfected with SLC24A6 siRNA or treated with FK506, an inhibitor of calcineurin. Furthermore, we investigated SLC24A6 expression, calcineurin phosphatase activity, and phospho-BAD in aorta tissues of the diabetics, STZ-induced diabetic monkeys, and db/db mice.

Results: Lenti-SLC24A6 transfection induced a significant enhancement in apoptotic cells. The overexpression of SLC24A6 in HEAC caused a significant increase in [Ca²⁺]_i, with significantly increased calcineurin phosphatase activity and decreased phospho-BAD. When compared with low-glucose culture for 96 h, high-glucose culture resulted in a 3.2-fold increase in apoptotic cells, a 5-fold increase in SLC24A6 levels, a 2.2-fold increase in calcineurin phosphatase activity, and a 3.4-fold decrease in phospho-BAD in HAEC. Both siRNA-mediated knockdown of SLC24A6 and treatment with FK506 significantly lowered the number of apoptotic cells induced by high glucose. In aorta tissues, it was found that both SLC24A6 levels and calcineurin phosphatase activities significantly increased in the diabetics, STZ-induced diabetic monkeys, and db/db mice when compared with their corresponding controls. However, phospho-BAD was detected with significantly decreased levels in these diabetic aorta tissues.

Conclusion: The current data demonstrated that SLC24A6 maybe play an important role in high glucose-induced apoptosis of aortic endothelial cells. We also presented evidence that SLC24A6 was involved in regulation of intracellular Ca²⁺ concentration, which then affected calcineurin phosphatase activity and phosphorylated level of BAD. The study suggested that SLC24A6-mediated Ca²⁺/calcineurin pathway could be a novel component in the pathogenesis of diabetic macrovascular complication.

MiR-216a regulates autophagy during vascular senescence

R. Menghini¹, V. Casagrande¹, A. Marino¹, M. Cardellini¹, E. Martelli², A. Ippoliti², R. Lauro¹, M. Federici¹

¹Internal Medicine, ²Surgery, University of Rome Tor Vergata, Italy.

Background and aims: Aging is one of the major risk factors for type 2 diabetes mellitus and atherosclerosis. Among the age associated functional and structural changes, of particular note is the decline in endothelial function. Autophagy, an intracellular catabolic process involved in protein and organelle degradation via the lysosomal pathway, declines with aging leading to the accumulation of intracellular waste products, and there is a clear overlap between the signaling networks regulating both aging and autophagy. The role of autophagy in diabetic vascular disease is poorly understood, but basal autophagy is considered a survival mechanism safeguarding cells against cellular distress, in particular oxidative injury, metabolic stress and inflammation, by removing harmful modified proteins and damaged components. The importance of the delicate and coordinated regulation of autophagic responses during metabolic homeostasis is clear, and small-molecule modulators of autophagy or central molecules controlling this process could facilitate the exploitation of this adaptive pathway for therapeutic interventions against metabolic and inflammatory diseases. Among modulators, microRNAs may represent good candidates for regulating autophagy.

Materials and methods: Computational analysis reveals that crucial autophagy related genes, such as Beclin1 and Atg5 are potential targets of miR-216a, a microRNA that is highly expressed as a consequence of diabetes. First, we compared the miR-216a expression in old HUVECs (PDL44) versus young cells (PDL8) and in the presence of high glucose levels (25 mM). Then we performed transfection experiments in HUVECs in order to modulate miR-216a expression. Finally we investigate the role of miR-216a *in vivo* in atherosclerotic plaques.

Results: Our results show a significant upregulation of miR-216a expression during aging and glucotoxicity, suggesting a downstream effect of post-transcriptional suppression of target genes, leading to the signalling abnormalities in the aging phenotypes. Moreover, in the same conditions, expression of Beclin1 and Atg5 was correspondingly downregulated, as assessed by RT-PCR and Western blot analysis. Transfection of PDL44 endothelial cells with an oligonucleotide that decreases miR-216a level (AS216a) permits an increase in Beclin1 and Atg5 expression, both at mRNA and protein levels. Conversely, overexpression of the miR-216a precursor decreases Beclin1 and Atg5 mRNA and protein expression levels in PDL8 cells. Preliminary analysis indicates that overexpression of miR-216a in young cells results also in a mRNA reduction of a putative target gene TP53INP1. Because autophagy plays a central role in atherosclerotic plaque stabilization we examined miR-216a, Beclin1 and Atg5 expression in plaques from patients who underwent carotid endarterectomy for symptomatic disease, confirming a negative correlation between miR-216a and autophagic genes mRNA level in an *in vivo* setting (R = -0.4, p<0.005). Furthermore, miR-216a expression in atherosclerotic plaque was correlated with HOMA-IR (R = 0.32; p<0.05).

Conclusion: Our data suggest that vascular senescence is associated to decreased expression of autophagy genes as a consequence of increased miR-216a expression, a microRNA particularly overexpressed in diabetic vascular disease.

Impact of pancreatic endothelium on secretory capacity and proliferation of pancreatic islet cells

M. Visa, M. Soty, P. Casini, A. Novials;

Laboratori Diabetis i Obesitat, IDIBAPS, Barcelona, Spain.

Background and aims: The pancreatic islets are one of the most vascularised organs of the body. Beta-cells are not directly exposed to the blood flow but are separated from the blood by a thin layer of endothelial cells (EC). The close proximity of EC and beta-cells suggests that there is a cross-talk relationship between these both cell types. The main objective of this work is to investigate if pancreatic endothelium could affect islet cell function and growth.

Materials and methods: Rat pancreatic islets were isolated using density gradient and then, were disaggregated with trypsin treatment or used to isolate EC. For the pancreatic EC extraction, islets were placed onto collagen gel and EC grown on this base. After one week, EC were trypsinized and were maintained in culture until passage number 8-10. The purified EC were identified by immunohistochemistry for expression of von Willebrand factor (vWF) and CD31. Islet disaggregated cells were cultured in the presence or absence of EC. Islet disaggregated cells were characterised by immunohistochemistry for expression of insulin and glucagon. To investigate the impact of the pancreatic endothelium on beta-cell function, we measured insulin secretion in response to glucose. Growth capacity of islet cells was determined by staining of the proliferation marker, Ki67.

Results: Immunofluorescence staining showed that islets EC expressed vWF and CD31. In disaggregated islets, the insulin secretion in response to 16.7mM glucose concentration was increased of 3.4 fold compared to 5.5mM glucose concentration. Interestingly, disaggregated islets cultured during three days with EC showed greater insulin secretion capacity in response to the glucose (5.1 fold) than single disaggregated islets. This increase was more important after six days of co-culture (9.4 fold). The immunofluorescence staining for pancreatic hormones showed well-done disaggregation of islets with the presence of single cells with expression of glucagon or insulin. Nevertheless, in the presence of EC, the disaggregated islets seem to reorganise in cell clusters showing insulin but also glucagon expression. Moreover, the presence of EC allowed the proliferation of islet cells which was demonstrated by Ki67 immunolabelling in the nucleus of glucagon and insulin-marked cells.

Conclusion: We showed that EC basement promotes the capacity of insulin secretion in response to glucose and the proliferation of islet cells.

Even mild hyperglycaemia disturbs vascular homeostasis in humans

B.A. Lemkes¹, S.E. Siegelaa¹, M. Nieuwendorp¹, W. Kulik², J.C.M. Meijers³, J.B.L. Hoekstra¹, F. Holleman¹;

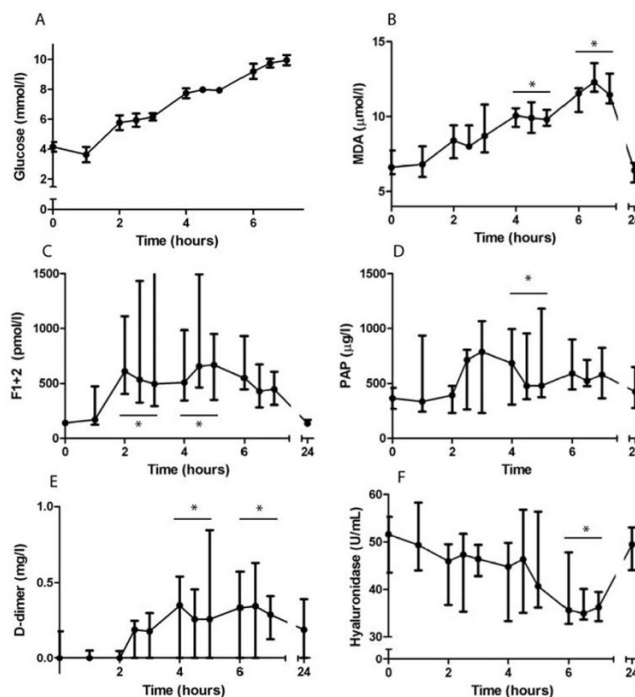

¹Internal Medicine, ²Laboratory genetic metabolic diseases, ³Vascular medicine, Academic Medical Centre, Amsterdam, Netherlands.

Background and aims: Hyperglycemia induces oxidative stress, damage to the endothelial glycocalyx and a prothrombotic shift in coagulation and fibrinolysis. These factors are known contributors to vascular disease but it is unknown at what glucose level these changes occur. The aim of this study was therefore to determine the level of glycemia at which these changes start.

Materials and methods: In 11 healthy young males we performed a stepwise normo-insulinemic hyperglycemic clamp at plasma glucose (PG) levels of 6, 8 and 10 mmol/l for two hours each (fig A). Octreotide was infused to suppress endogenous insulin release. Measurements were performed at baseline, after a 1-hr octreotide run-in, every 30 minutes during the clamp and at 24-hrs. Oxidative stress was assessed by determining malondialdehyde (MDA) using tandem mass spectrometry; coagulation activation by von Willebrand factor (vWf, Elisa) and prothrombin fragment 1+2 (F1+2, Elisa); fibrinolysis by plasmin-alpha2-antiplasmin complexes (PAP, Elisa) and d-dimer (BCS-XP); and glycocalyx turnover by hyaluronic acid (HA) and hyaluronidase (both Elisa). Differences between plateaus were assessed by a Wilcoxon signed ranks test for paired data. The influence of time on the measurements at each glucose level was assessed using the Friedman test.

Results: MDA showed a gradual increase highly correlating with PG ($p=0.82$, $p<0.001$, fig B). F1+2 significantly increased at 6 mmol/l, maintaining the same level at all PG concentrations (fig C) and both PAP and d-dimer increased significantly at 8 mmol/l, indicating coagulation activation followed by fibrinolysis (fig D&E). vWf showed a small, but significant decrease at all PG levels (max 9%, $p=0.01$). No difference in HA levels was detected, however hyaluronidase showed a gradual decrease, significant at 10 mmol/l (fig F), indicating increased hyaluronidase substrate binding. There was no indication of a cumulative effect of PG on any of the parameters.

Conclusion: Our results show that glucose-induced changes to vascular homeostasis already start at near normal glucose levels. Furthermore our study reveals a dose-dependent effect of glucose on MDA formation and an on-off phenomenon for glucose induced coagulation activation, while changes to the endothelial glycocalyx occur at glucose levels of 10 mmol/l or higher. These results give us more insight in the glucose driven mechanisms of vascular complications in humans.

* $p<0.05$ compared to $t=1$, after 1-hr octreotide infusion
Glucose values are expressed as mean [SD], outcome parameters as median [IQR]

Oxygen increases arterial stiffness and blood pressure in patients with type 1 diabetesD. Gordin¹, L. Bernardi², M. Rosengård-Bärlund¹, V.-P. Mäkinen¹, A. Soro-Paavonen¹, C. Forsblom¹, P.-H. Groop¹;¹Medicine, Division of Nephrology, Folkhälsan, Institute of genetics, Folkhälsan research center, Helsinki, Finland, ²Department of Internal Medicine, University of Pavia and IRCCS Policlinico S. Matteo, Pavia, Italy.

Background and aims: Oxygen is often empirically used in the treatment of different medical conditions. However, hyperoxia has in a few recent studies been shown to increase systemic arterial stiffness in healthy volunteers. Although arterial stiffness is increased in patients with type 1 diabetes (T1D), no studies have yet explored systemic arterial stiffness in response to hyperoxia in this patient group. Therefore, we examined the effect of short-term oxygen administration on arterial stiffness, blood pressure, and heart rate in a large number of patients with T1D and healthy subjects.

Materials and methods: Altogether 98 patients with T1D and 49 control subjects were studied. Continuous finger pressure waveforms were monitored with a digital plethysmograph (Finapres) both at steady state (10 min) and during hyperoxia (15 min). The augmentation index (AIx) was calculated from the waveforms and used as an estimate of arterial stiffness. In order to validate the method (estimate central aortic stiffness) we calculated a transfer function after measuring pressure waveforms simultaneously from the radial artery (applanation tonometry, Sphygmocor) and the finger (Finapres) in 15 subjects.

Results: The groups did not differ with regard to age (31.9 ± 0.7 [T1D] vs. 32.7 ± 1.3 [Controls], $P = \text{NS}$). AIx increased from 14.1 ± 0.9 to $17.6 \pm 0.8\%$, ($P < 0.001$) in patients with T1D and from 10.7 ± 1.5 to 12.6 ± 1.3 ($P < 0.05$) in controls in response to hyperoxia (Figure). However, the increase in AIx (3.4 ± 0.5 vs. $1.5 \pm 0.7\%$, $P = 0.03$), systolic (6.7 ± 1.2 vs. 1.2 ± 2.0 mmHg, $P = 0.02$) and diastolic 3.6 ± 0.7 vs. -0.2 ± 1.1 mmHg, $P = 0.004$) blood pressure was more pronounced in patients with T1D compared to controls. Oxygen saturation was lower in patients with T1D ($97.2 \pm 0.1\%$) than in healthy controls at baseline ($97.7 \pm 0.1\%$, $P < 0.01$) and increased more in response to hyperoxia (1.5 ± 0.1 vs. $1.1 \pm 0.1\%$, $P = 0.03$).

Conclusion: Arterial stiffness and blood pressure increased more in response to hyperoxia in patients with T1D than in healthy subjects, suggesting that oxygen should be administered cautiously in such patients. The rapid changes rather indicate a functional mechanism than structural modifications of the arterial wall.

AIx (%)

Elevated frequencies of CD34+VE-cadherin+ endothelial progenitor cells (EPCs) and negative correlation between endothelial dysfunction and EPCs in children with type 1 diabetes on insulin pump therapyB. Głowińska-Olszewska¹, M. Moniuszko², A. Hryniewicz¹, M. Jeznach², M. Dąbrowska³, W. Łuczyński¹, A. Bodzenta-Łukaszyk², A. Bossowski¹;¹Department of Pediatrics, Endocrinology, Diabetology with Cardiology Division, Medical University, ²Department of Allergy and Internal Medicine, Medical University, ³Department of Hematological Diagnostics, Medical University, Białystok, Poland.

Background and aims: Endothelial progenitor cells (EPCs) are bone marrow derived pluripotent vascular progenitor cells capable to contribute to reendothelialization and neovascularization. The low number of circulating EPCs has been established as a biomarker of cardiovascular risk, and is known to be reduced in adults with atherosclerosis risk factors. In healthy children EPCs number is higher than in adults, but data on young populations with risk factors are limited. The aim of the study was to assess vascular function and structure together with EPCs in children with type 1 diabetes and to establish correlations between studied parameters.

Materials and methods: We compared 31 children and adolescents with diabetes type 1 (aged mean 14.4 yrs, diabetes duration mean: 5.7 yrs, HbA_{1c} level: 8.8%, all treated with insulin pumps) with 17 healthy age and gender matched control children. EPCs were analysed with use of the multicolor flow cytometry with combination of monoclonal antibodies against CD34, CD144 (VE-cadherin) and CD 309 (VEGFR-2). sICAM-1, hsCRP, thrombomodulin, adiponectin levels were assessed by ELISA methods. Vascular function and structure were evaluated by flow-mediated dilation (FMD) and carotid intima-media thickness (IMT) ultrasonographically. Data are presented as mean \pm SD, median or frequencies. T-student and median test were used for comparison between two groups, for correlations Pearson's analysis was performed.

Results: CD34+, and CD34+VEGFR-2+ EPC frequencies were similar in both groups ($P = 0.71$, $P = 0.8$ respectively). CD34+VE-cadherin+ and VE-cadherin+ frequencies were higher in diabetic children compared to healthy group ($P = 0.008$, $P = 0.039$ respectively). FMD was lower (9.3% vs 12.3% , $P = 0.03$), and IMT was higher (0.53 vs 0.45 mm, $P = 0.01$) in diabetic children. hsCRP, sICAM-1 and cholesterol levels were higher in the study group. There was a significant relationship between CD34+VEGFR-2+ and BMI ($r = 0.35$, $P = 0.04$), HDL ($r = -0.3$, $P = 0.04$), sICAM-1 ($r = 0.47$, $P = 0.019$), and FMD ($r = -0.54$, $P = 0.002$). CD34+VE-cadherin+ correlated with BMI ($r = 0.4$, $P = 0.04$) and FMD ($r = -0.6$, $P = 0.031$). HbA_{1c} level was not related to EPC counts.

Conclusion: Abnormalities of endothelial function and structure are present in poorly metabolically controlled children with diabetes type 1. Contrary to adult population with diabetes, diabetic children demonstrated unchanged (CD34+VEGFR2+) or even increased (CD34+VE-cadherin+) frequencies of EPC, that correlated negatively with endothelial function. This may be result of the effective mobilization of endothelial progenitor cells in young population at increased risk for atherosclerosis in order to repair damaged endothelium.

1224

Determinants of circulating endothelial progenitor cell number in prediabetic subjectsA. Angelidi¹, J. Protosaltis¹, A. Gritzapis¹, I. Kornezos², T. Sergeantanis¹, K. Tzirogiannis¹, E. Boutati³, G. Dimitriadis³, A. Melidonis¹, S. Raptis³;¹Diabetes Center, Tzanio General Hospital, Piraeus, ²Department of Radiology, Tzanio General Hospital, Piraeus, ³Hellenic National Diabetes Center & Attikon University Hospital, Athens, Greece.

Background and aims: Endothelial Progenitor Cells (EPCs) originate primarily from the bone marrow and take part in postnatal neovascularization. Moreover, when incorporate into endothelial damaged areas, they replace the dysfunctional vascular endothelium which predisposes to atherosclerosis. On the contrary, reduced EPCs are found to be associated with increased cardiovascular risk. The aim of this study was to investigate the relation of EPC numbers with several cardiovascular risk factors among patients with prediabetes.

Materials and methods: A total of 39 volunteers without history of cardiovascular disease were recruited and underwent a 75gr OGTT in order to confirm the presence of prediabetes. We recorded for all the study population: waist circumference, waist to hip ratio, body mass index, smoking habit,

presence of metabolic syndrome (NCEP-ATP III & IDF criteria) and homeostasis model assessment of the insulin resistance (HOMA-IR). Additionally, we measured all the well-established biomarkers of cardiovascular risk and high sensitivity C-reactive protein (hs-CRP). Visceral fat mass was ultrasonographically measured using a strict protocol suggested from previous studies. Flow cytometry identified and quantified the EPCs (CD34+ CD133+ KDR+ cells). Stepwise multivariate regression analysis was performed to determine the possible correlations of EPCs to the above mentioned risk factors.

Results: Univariate regression analyses performed separately for all cardiometabolic parameters: EPC counts were not significantly associated with the presence of metabolic syndrome or the cumulative number of its components. Conversely EPC numbers were significantly correlated with visceral fat ($\rho = -0.34$, $p = 0.040$), median arterial pressure ($\rho = -0.44$, $p = 0.009$), HOMA-IR ($\rho = -0.40$, $p = 0.031$), hs-CRP ($\rho = -0.44$, $p = 0.006$), waist circumference ($\rho = -0.41$, $p = 0.017$) and total cholesterol ($\rho = 0.47$, $p = 0.003$). However in multivariate regression analysis visceral fat only remained significantly associated with the number of EPCs (OR=0.79, 95%CI:0.64–0.98, $p = 0.032$).

Conclusion: Circulating endothelial progenitor cells in prediabetic subjects are negatively and independently correlated to visceral fat mass, which supports the importance of lifestyle modifications - and predominantly weight reduction - to prevent and minimize the progress of cardiovascular disease.

Endothelial but not smooth muscle progenitor cells are reduced in type 2 diabetic patients independent of macrovascular disease

J. van Ark¹, J. Moser¹, I.E. Pop², C.P.H. Lexis³, I.C.C. van der Horst³, F. Bekkema⁴, C.J. Zeebregts⁴, H. van Goor¹, B.H.R. Wolffenbuttel², J.L. Hillebrands¹

¹Pathology and Medical Biology, ²Endocrinology, ³Cardiology, ⁴Surgery - Vascular Surgery, University Medical Center Groningen, Netherlands.

Background and aims: Individuals with type 2 diabetes mellitus (T2DM) have increased rates of macrovascular disease (MVD), including coronary artery disease (CAD) and peripheral artery disease (PAD). Increasing evidence indicates involvement of aberrant circulating vascular progenitor cell frequency and function in the development of MVD. Endothelial Progenitor Cells (EPCs) are involved in maintaining endothelial integrity and can be considered a mirror of vascular repair capacity. On the other hand, Smooth Muscle Progenitor Cells (SMPCs) may promote luminal narrowing and aggravate development of MVD. However, the relationship between EPCs and SMPCs, and the development of accelerated MVD in T2DM is still unknown. We therefore assessed vascular progenitor cell frequency in T2DM patients and non-diabetic subjects with or without MVD.

Materials and methods: Peripheral blood was obtained from T2DM patients and non-diabetic subjects with or without documented CAD or PAD. The following groups were included: group 1: T2DM, no PAD/CAD ($n = 25$), group 2: T2DM, with CAD ($n = 14$), group 3: T2DM, with PAD ($n = 21$), group 4: healthy age-matched controls ($n = 18$), group 5: no T2DM, with CAD ($n = 8$), group 6: no T2DM, with PAD ($n = 21$). Circulating vascular progenitor cells were analyzed by flowcytometry using antibody cocktails against CD34/KDR/CD133 (EPCs), and CD14/CD105 (SMPCs).

Results: The number of CD34+ EPCs was reduced by 35% in T2DM patients with or without MVD compared with non-diabetic subjects [with or without MVD] (260 ± 15 vs. 353 ± 23 CD34+ cells/ 10^6 events respectively, $p < 0.001$). When comparing healthy control subjects with T2DM patients [with or without MVD], a 2.8-fold reduction in CD34+KDR+ EPCs was found (14 ± 4 vs. 5 ± 1 CD34+KDR+ cells/ 10^6 events, respectively, $p < 0.01$). However, a significant decrease ($p < 0.05$) in the number of CD34+KDR+ EPCs in non-diabetic subjects with CAD or PAD (4 ± 1 and 6 ± 1 CD34+KDR+ cells/ 10^6 events, respectively) compared with healthy control subjects (14 ± 4 CD34+KDR+ cells/ 10^6 events) was also observed. In contrast to EPCs, the frequency of circulating CD14+CD105+ SMPCs was not affected by T2DM compared with non-diabetic subjects. However, in non-diabetic patients the presence of PAD, but not CAD, was associated with an increase in SMPC frequency compared with healthy control subjects (3.2-fold increase; 3280 ± 494 vs. 1020 ± 332 CD14+CD105+ cells/ 10^6 events, $p < 0.01$). Diabetic patients with MVD had similar numbers of circulating SMPCs as diabetic patients without MVD.

Conclusion: The number of circulating CD34+ EPCs is significantly reduced in T2DM patients compared with non-diabetic subjects, independent of the presence or absence of MVD. Compared with healthy controls, the number of CD34+KDR+ EPCs is significantly decreased in both diabetic subjects,

and non-diabetic subjects with MVD. However, circulating SMPC numbers are not affected by T2DM. Therefore, an altered balance between circulating EPCs and SMPCs in favour of SMPCs may contribute to reduced vascular repair capacity and subsequent increased rates of MVD in T2DM.

Close relationship between serum hyaluronan levels and vascular smooth muscle function in patients with type 2 diabetes

M. Morita¹, S. Yano¹, Y. Ishibashi², N. Nakata¹, S. Tanaka¹, S. Kurioka³, T. Sugimoto¹

¹Internal Medicine 1, Shimane University Faculty of Medicine, Izumo,

²Vascular Lab, Shimane University Faculty of Medicine, Izumo, ³Diabetes, Komatsu Hospital, Osaka, Japan.

Background and aims: Since cardiovascular disease is the major cause of mortality in patients with type 2 diabetes, a surrogate marker for vascular function is urgently needed. Such a marker would allow initiation of early intervention. Currently, endothelium-dependent flow-mediated dilation (FMD) and endothelium-independent nitroglycerine-mediated dilation (NMD) are considered to be sensitive markers of vascular function. However, their clinical applications are limited because of technical and methodological problems such as nitroglycerin usage. On the other hand, hyaluronan is produced in the process of the tissue restoration after inflammation. Previous reports have indicated that the serum hyaluronan level is increased in patients with type 2 diabetes and is associated with metabolic markers including glycosylated hemoglobin (HbA1c) and body mass index (BMI). However, no study has as yet examined the relationship between hyaluronan and vascular function. Thus, we aimed to clarify whether hyaluronan can serve as a surrogate marker for vascular function.

Materials and methods: This study included 79 patients with type 2 diabetes (age, 62 ± 13 ; duration, 10.7 ± 9.0 years). Serum hyaluronan level in blood samples was measured using a latex immunoturbidimetric assay. Estimated glomerular filtration rate (eGFR) was calculated employing age, sex and serum creatinine concentrations. FMD and NMD were measured at the brachial artery using UNEXEF18G and expressed as changes in diameter. To evaluate the relationships of FMD and NMD to the serum hyaluronan level, uni- and multivariate regression analyses were performed.

Results: The mean (\pm SD) FMD and NMD were 4.4 ± 3.0 and $13.3 \pm 6.4\%$, respectively. In univariate regression analysis, FMD was significantly associated with age ($r = -0.490$, $p < 0.001$), diabetic duration ($r = -0.421$, $p = 0.001$), BMI ($r = 0.224$, $p = 0.030$), systolic blood pressure ($r = -0.240$, $p = 0.036$), eGFR ($r = 0.334$, $p = 0.002$) and hyaluronan ($r = -0.320$, $p = 0.004$). NMD was significantly associated with age ($r = -0.417$, $p < 0.001$), eGFR ($r = 0.248$, $p = 0.032$) and hyaluronan ($r = -0.392$, $p < 0.001$). In multivariate regression analysis, FMD was associated with age ($r = -0.399$, $p = 0.027$) and diabetic duration ($r = -0.276$, $p = 0.027$), whereas NMD was associated only with hyaluronan ($r = -0.401$, $p = 0.003$), suggesting elevated serum hyaluronan to possibly be responsible for dysfunction of vascular smooth muscle rather than the vascular endothelium.

Conclusion: The present study indicates that close relationship between hyaluronan levels and vascular smooth muscle function exists in patients with type 2 diabetes. Hyaluronan is a potential surrogate marker for vascular function in patients with type 2 diabetes, which is independent of other metabolic markers, although further study is necessary.

Vasoprotective effects of caloric restriction in aging and type 2 diabetes

R.M. Seica¹, T.M. Louro¹, A.M. Pereira¹, D. Carvalho¹, R. Fernandes², C.M. Sena¹

¹Institute of Physiology, IBILI, Faculty of Medicine, ²Institute of Pharmacology and Experimental Therapeutics, IBILI, Faculty of Medicine, University of Coimbra, Portugal.

Background and aims: Caloric restriction (CR) without malnutrition extends life span in a range of organisms including insects and mammals and lowers free radical production by the mitochondria. The direct effects of CR on vascular function and phenotype in aging are not well characterized. It is generally accepted that tonic release of nitric oxide (NO) from the endothelium exerts vasculoprotective and cardioprotective effects. The current study was undertaken to examine the effects of caloric restriction on endothelial

function, metabolic, glycation and oxidative stress markers, in old age Wistar and diabetic Goto-kakizaki (GK) rats.

Materials and methods: Wistar (W) and GK rats with twelve months old were progressively subject to CR up to 35% during 4 months and compared with ad libitum fed rats. The effects of CR were investigated on NO-dependent and independent vasorelaxation in isolated rat aortic arteries from the different groups. Metabolic profile, NO bioavailability, the accumulation of advanced glycation end-products (AGEs) and carboxymethyllysine (CML), the expression of the receptor for AGEs (RAGE) in the aorta and vascular oxidative stress were also evaluated.

Results: We have previously shown that aging was associated with increased endothelial dysfunction in both W and diabetic GK rats. In this work we show that GK rats exhibited a three-fold increment in vascular oxidative stress and in CML accumulation when compared with age-matched W rats. Diabetes-induced excess accumulation of reactive oxygen species in aorta resulted in vascular nitric oxide (NO)/cGMP dysfunction (decrement of 40 %, $p < 0.001$). Caloric restriction was able to retard the progression of endothelial dysfunction and significantly reduce aortic oxidative stress ($p < 0.001$) in W and diabetic GK rats. Furthermore, CML accumulation in aortic wall was sharply reduced and accompanied by a decrement in the expression of aortic RAGE in caloric-restricted fed animals. Noteworthy, the NO-cGMP pathway in the aorta of GK rats was partially reverted explaining the positive outcomes observed in the endothelial function of diabetic GK rats.

Conclusion: This study provides, to our knowledge, the first evidence that caloric restriction increases bioavailability of NO improving endothelial function by a mechanism that likely includes upregulation of eNOS and a decrement in glycation and oxidative biomarkers in aged type 2 diabetic rats. *Supported by: Faculty of Medicine, University of Coimbra*

Fluctuating hyperglycaemia induces higher levels of oxidative stress than sustained hyperglycaemia in insulin resistant rats

G. Rakipovski^{1,2}, J. Lykkesfeldt¹, K. Raun²;

¹University of Copenhagen, Frederiksberg, ²Diabetes and Obesity Pharmacology, Novo Nordisk A/S, Maaloev, Denmark.

Background and aims: Recent reports have shown that despite similar mean glycaemic exposure measured as HbA1c levels, the risks of developing macro-vascular complications can be different in diabetic patients. Repeated episodes of short term hyperglycaemia not necessarily resulting in altered HbA1c levels have been hypothesized to promote the production of reactive oxygen species (ROS) more than sustained hyperglycaemia and thus lead to increased levels of oxidative stress. In the present study, we compare effects of fluctuating with sustained high or low levels of glucose on oxidative stress markers.

Materials and methods: A total of 30 catheterized diet induced obese (DIO) insulin resistant male Sprague-Dawley rats (38 weeks) were randomized into four weight-matched groups ($n = 7-8$) and connected to an automated blood sampling system (Accusampler[®]) for blood withdrawal and intravenous glucose infusions. Animals were fasted for 6 hours prior to receiving either a continuously high (CHG) or low (CLG) or pulsating (FLU) infusion of glucose for 96 hours. The FLU group received nine daily 30 min glucose infusions separated by 2.5 h. In total FLU and CLG groups received equal amounts of glucose whereas the CHG group received three times this amount. Plasma glucose and insulin was monitored during the complete study period. Plasma malondialdehyde (MDA), ascorbate (ASC) and dehydro-ascorbate (DHA), was measured every 24th hours. Plasma MDA was used as a biomarker of oxidative damage to lipids whereas plasma ASC and DHA were used to evaluate the antioxidant status by calculating the ascorbate oxidation ratio as % DHA of total ASC.

Results: All groups had similar basal plasma glucose (~ 6.5 mmol/l) and insulin (~ 600 pmol/l) levels. Hyperglycaemia (> 25 mmol/l) and hyperinsulinemia (> 2700 pmol/l) were immediately manifested in the CHG group and maintained throughout the study. The FLU group showed regular oscillation of glucose $\sim 20-22$ mmol/l and insulin ~ 2500 pmol/l at peak level and returned back to normal levels in between pulses. The CLG group displayed an immediate increase in glucose ~ 12 mmol/l but levelled out during the infusion period and was comparable to controls at the end. In turn - plasma insulin levels were gradually increased during infusion to levels of ~ 2000 pmol/l. Plasma MDA were significantly increased in the FLU group at 72 and 96 hours (72 hours: VEH: 1.42 ± 0.15 vs. FLU: 2.3 ± 0.15 ; 72 hours: VEH: 1.34 ± 0.15 vs. FLU: 2.15 ± 0.15 ; $p < 0.05$), whereas the CHG group only showed significance at 72 hours (VEH: 1.42 ± 0.15 vs. CHG: 2.35 ± 0.16 ; $p < 0.05$). Plasma ASC and %DHA were not different among groups ($p = ns$; all cases).

Conclusion: We show that fluctuating glucose levels lead to oxidative stress similarly to that of sustained hyperglycaemia despite a much lower total glycaemic exposure. Thus our data supports the notion that fluctuating glucose may be relatively more deleterious than sustained hyperglycaemia.

Increasingly expressed sulfonylurea-regulated, non-selective cation channel mediates myocardial dysfunction and arrhythmias of obese rats after ischaemic injury

Y. Bao¹, Y. Yu², X. Sun², S. Lu¹, Y. Wu¹;

¹West China medical school, ²West China hospital, Sichuan University, Chengdu, China.

Several studies have discovered that the SUR1-regulated nonspecific cation (NC_{Ca-ATP}) but not K_{ATP} channels are upregulated in ischemic astrocytes, and block of SUR1 with sulfonylurea (SU) reduced cerebral edema, infarct volume and mortality. Recent patch-clamp studies also found similar SUR-1 regulated non-selective cation channel (NSC_{Ca}) in myocardial cells, but the effects of blocking NSC_{Ca} by SUs on ischemic myocardium have not been reported. The aim of the study was to identify the up-regulation of NSC_{Ca} in myocardial cells after ischemic injury, and to evaluate the effects of gliclazide on myocardial infarct size, post-ischemic cardiac function and arrhythmia in obese rats with

cardiac ischemia-reperfusion (I/R) injury. Diet-induced obese rats divided into 4 groups. MI group rats received subcutaneous Isoprenaline (100mg/kg) shots to create myocardial I/R injury, and non-MI group rats received subcutaneous saline shots. These rats were sacrificed 24 hours later and had their hearts taken and prepared for immunofluorescence imaging. SU group and Control group rats were given gliclazide (1 mg/kg) or saline lavage Q12h for 48 hours. These rats were subjected to myocardial I/R injury by Isoprenaline (100mg/kg) injection subcutaneously 24 hours after first lavage. ECG was recorded and all the arrhythmias were analyzed with arrhythmia severity index (ASI). At the end of 24 hours after I/R injury, hemodynamic parameters were measured with an electromanometer. The hearts were harvested and cut into 1mm slides. The infarct-size was evaluated with TTC staining, calculated with Image-Pro Plus 6.0. Obvious up-regulation of SUR-1 was observed at the vascular wall of the heart in MI group, but not in non-MI group. For rats in the SU group and control group, blood glucose was only slightly declined during study. The mortality was 63.64% (14/22) in control group and 45.45% (10/22) in SU group (NS). The frequency of serious arrhythmia was lower in SU group (ASI: 2.14 ± 1.83 vs. 4.00 ± 2.85 , $p < 0.05$). Gliclazide administration reduced myocardial infarct size ($32.7\% \pm 9.1\%$ vs. $48.6\% \pm 12.8\%$, $p < 0.05$) and improved diastolic function as the left ventricle end-diastolic pressure (LVEDP) was lower and maximum rate of decrease of LVP ($-(dp/dt)_{max}$) was higher in SU group (Table). Our findings indicate that NSC_{Ca} channels is involved in development of myocardial dysfunction and arrhythmias, and that targeting SUR1 may provide a new therapeutic approach to ischemic cardiac injury. Table 1. Hemodynamic performance of obese rats after I/R injury

Hemodynamic performance of obese rats after I/R injury		
	Control group (n=22)	SU group (n=22)
LVSP	120.92 ± 13.53	138.12 ± 24.86
LVEDP	6.86 ± 2.42	$2.51 \pm 3.77^*$
(dp/dt) _{max}	2192.39 ± 1461.66	3678.90 ± 1751.96

Echocardiographic changes in rats with metabolic syndrome observed after long-term cola beverage drinking

J. Milei¹, M. Otero Losada¹, H. Gomez Llambi¹, D.R. Grana¹, D. Suarez¹, F. Azzato^{1,2}, G. Ambrosio²;

¹Instituto de Investigaciones Cardiológicas (ININCA) UBA - CONICET, Buenos Aires, Argentina, ²Division of Cardiology, University of Perugia School of Medicine, Italy.

Background and aim: Previously we reported metabolic syndrome-associated alterations in a cola-drinking rat model. Metabolic syndrome has been linked to increased risk of type II diabetes and cardiovascular disease. This work evaluates whether chronic drinking of cola beverages may affect cardiac geometry.

Methods: 48 male Wistar rats drank regular cola beverage (C), light cola beverage (L) or tap water (W) ad libitum (n=16 per group). After 6 months (treatment) 50% of C₆, L₆ and W₆ rats were euthanized. Heart and thoracic and abdominal aorta were excised and harvested for light microscopy (histopathology) at the time of euthanasia. Echocardiograms (ATL 3000 HDI, Bethold, WA, USA) and systolic blood pressure (SBP) (tail cuff plethysmography, electro-sphygmomanometer PE-300, Physiograph MK-IIIS, Narco Bio-Systems, Austin, Texas) were recorded in awake rats at the beginning of the study (baseline) and after treatment (6 months). At the beginning of the study all three experimental groups were indistinguishable from each other according with variables of interest.

Results: C₆ and L₆ groups were respectively different from W₆ group based on: (I). Left ventricular diastolic dimension (LVDD, mm): 7.4 ± 0.3 (+9%, mean diff.= 0.60, CI_{95%}= 1.10 to 0.10, t= 3.19, $p < 0.01$) and 7.3 ± 0.7 (+7%, mean diff.= 0.50, CI_{95%}= 0.99 to 0.09, t= 2.71, $p < 0.05$) vs. 6.8 ± 0.4 ; (II). Left ventricular diastolic volume (LVDV, ml): 0.34 ± 0.04 (+26%, mean diff.= +0.07, CI_{95%}= 0.13 to 0.01, t= 3.32, $p < 0.05$) and 0.33 ± 0.06 (+22%, mean diff.= +0.06, CI_{95%}= 0.12 to 0.01, t= 2.90, $p < 0.05$) vs. 0.27 ± 0.04 ; (III). Systolic volume (SV, ml): 0.31 ± 0.04 (+24%, mean diff.= 0.60, CI_{95%}= 0.12 to 0.01, t= 2.76, $p < 0.05$) and 0.31 ± 0.03 (+24%, mean diff.= 0.60, CI_{95%}= 0.12 to 0.01, t= 2.80, $p < 0.05$) vs. 0.25 ± 0.04 ; (IV). Relative wall thickness (RWTh): 0.37 ± 0.03 (-8%, mean diff.= 0.60, CI_{95%}= 0.003 to 0.077, t= 2.90, $p < 0.05$) and 0.36 ± 0.05 (-10%, mean diff.=

0.60, CI_{95%}= 0.004 to 0.076, t= 2.90, $p < 0.05$) vs. 0.40 ± 0.03 . C₆ was different from W₆ based on cardiac output (ml/min): 148 ± 20 (+29%, mean diff.= +33, CI_{95%}= 66.0 to 0.01, t= 3.06, $p < 0.05$) vs. 115 ± 21 . Treatment had no effect on heart rate (bpm): 470 ± 46 (C₆), 457 ± 44 (L₆), 469 ± 36 (W₆). The necropsy findings were scarce and showed no relation to treatment.

Conclusions: Six months' cola beverage drinking led to increases in diastolic and systolic volumes and left ventricle posterior wall thinning that resulted in larger cardiac output without affecting heart rate. Factors responsible for cardiac remodeling in long-term light cola drinking animals are to be identified. Supported by: CONICET

Endoglin levels in the kidney are correlated to fibrosis in hypertensive and diabetic rats

A.M. Blázquez-Medela¹, O. García-Sánchez¹, F.J. López-Hernández^{1,2}, J.M. López-Novoa¹, C. Martínez-Salgado^{1,2};

¹Physiology and Pharmacology, Renal and Cardiovascular Pathology Unit, Salamanca, ²IECSCYL, University Hospital of Salamanca, Spain.

Background and aims: Hypertension is, after diabetes, the second most common cause of chronic renal disease. Renal hypertension puts stress and increases pressure on the kidney. Several authors have suggested the possible link of endoglin, a member of the receptor system of transforming growth factor-beta 1, with different vascular alterations. Endoglin is known to be constitutively expressed in endothelial cells and plays a critical role in both vascular development and endothelial function. Previous studies from our research group showed that endoglin levels are altered in *in vivo* experimental models of diabetes, but there are no studies relating endoglin with the development of renal fibrosis

Materials and methods: We have studied endoglin levels in kidneys from 8 different rat experimental groups: Wistar and Spontaneously Hypertensive Rats (SHR), each divided into 4 experimental groups: sham-operated, diabetic rats (after an injection of 60 mg streptozotocin/kg body weight), uninephrectomized rats (UNX, right kidney removed in order to accelerate the development of disease in the remnant kidney) and UNX diabetic rats. We kept glycaemia levels between 300 and 400 mg/dL in diabetic rats, injecting daily insulin doses. Monthly, both 24 h-urine samples (in metabolic cages) and plasma samples were collected. We assessed renal function by creatinine clearance and determination of proteinuria, albuminuria and blood ureic nitrogen. 8 months after the induction of diabetes, hearts and kidneys were removed, and the expression of endoglin, fibronectin and type I collagen in renal tissue was analyzed (by Western blot and PCR), as well as the presence of left ventricular hypertrophy.

Results: Renal function impairment started at 4th-5th month in UNX rats, either in the presence or absence of diabetes. At the 8th month, renal hypertrophy was observed in UNX groups when compared to Sham rats. We also observed LVH in SHR when compared to Wistar rats. SHR UNX had the largest hearts and, interestingly, diabetic SHR had smaller hearts than their control group (non diabetic SHR). Kidneys of UNX (SHR and Wistar) rats contained larger amounts of fibronectin than kidneys of sham-operated rats. Kidneys from SHR UNX presented the higher expression of type I collagen. Interestingly, endoglin expression was directly correlated with extracellular matrix synthesis, as we observed the highest endoglin expression in SHR UNX kidneys.

Conclusion: These data suggest the existence of a direct correlation between endoglin expression and renal fibrosis in either hypertensive or diabetic rats.

Hyperbaric oxygen therapy does not worsen the cardiac function and oxidative state of diabetic rats

R. Benkő^{1,2}, V.A. Ágoston², N. Béres¹, M. Szabó¹, K. Ihionvien¹, A. Rozsits¹, Z. Miklós¹, G. Dunay¹, Z. Benkő¹, M. Szepesi¹, L. Kiss¹, Z. Nagy², E.M. Horváth¹;

¹Institution of Human Physiology and Clinical Experimental Research, Hungary, ²Department of Cardiology, Laboratory of Cell Biology, Section of Vascular Neurology, Semmelweis University, Budapest, Hungary.

Background and aims: Hyperbaric oxygen therapy (HBOT) is frequently used in diabetic patients with ulcerated wounds; however its ability to increase oxidative stress inducing accelerated β -cell death and cardiovascular complications casts doubts.

Materials and methods: Wistar rats (20) weighing 300 g were administered with a single dose of 70 mg/kg streptozotocin to induce diabetes mellitus (DM). The 24-hour blood glucose profile and cardiac function (ultrasound measurements) of diabetic animals and 20 controls (C) were measured three weeks after the induction of diabetes. 10 diabetic (DM HBOT) and 10 controls (C HBOT) underwent one-hour long hyperbaric oxygen treatment (HBOT: 2.5 bar) 12 times (in 16 days). Following HBOT and 8 weeks after streptozotocin treatment, ultrasound and blood glucose measurements were repeated. Blood plasma and lymphocyte samples were collected. Malonyldialdehyde assay (MDA) were performed on the plasma samples and nitrotyrosine immunostaining (NT) was done on lymphocyte smears. For data analysis ANOVA and Tukey's post hoc test were implemented.

Results: Blood glucose concentrations were significantly elevated in both diabetic groups (DM: 23.92 ± 1.91 , DM HBOT: 22.52 ± 1.03 ; $p < 0.0001$ vs. C: 4.84 ± 0.18 , C HBOT: 4.6 ± 0.2). HBOT did not affect blood glucose levels. On the 3rd week of diabetes there were no significant difference between diabetic and control groups in ejection fraction (EF), but stroke volume (SV) (DM: 0.181 ± 0.028 , DM HBOT: 0.183 ± 0.044 ; $p < 0.05$ vs. C: 0.251 ± 0.068 , C HBOT: 0.232 ± 0.054) and end diastolic volume (EDV) (DM: 0.381 ± 0.072 , DM HBOT: 0.404 ± 0.070 ; $p < 0.05$ vs. C: 0.487 ± 0.095 , C HBOT: 0.449 ± 0.099) were significantly lower in diabetic animals. By time the decrement of EF in diabetic rats reached the level of significance. (DM: 32.485 ± 8.206 , DM HBOT: 33.657 ± 10.383 ; $p < 0.0001$ vs. C: 53.339 ± 8.007 , C HBOT: 50.369 ± 9.631) HBOT did not alter the cardiac parameter of control rats. HBOT did not reduced EF and SV in diabetic rats, however it improved EDV (log(EDV) DM: -0.6375 ± 0.0532 vs. DM HBOT: -0.5286 ± 0.09299 , $p < 0.05$). Plasma MDA levels were significantly elevated in diabetic rats compared to both control groups. (DM: 23.5 ± 17.59 ; $p < 0.05$ vs. C: 9.5 ± 4.48 ; $p < 0.01$ vs. C HBOT: 6.1 ± 1) Interestingly HBOT tended to decrease oxidative stress in all animals: there was no significant difference between diabetic HBOT rats and any other group (DM HBOT: 14.8 ± 11.7). Nitrate stress was significantly higher in both DM groups than in the control groups, but NT positivity not altered by HBOT (DM: 38.1 ± 10.1 , DM HBOT: 41.2 ± 7.8 ; $p < 0.05$ vs. C: 20.4 ± 10 , C HBOT: 22 ± 10.5)

Conclusion: HBOT has no negative effect on the cardiac functions of rats having fully developed insulin dependent diabetes mellitus. HBOT neither did increase oxidative-nitrate stress. According to our results HBOT may not increase cardiovascular risk of type1 diabetic patients.

expression of FN. Transfection with miR-146a mimics restored miR-146a level and decreased FN mRNA and protein production, whereas miR-146a antagonists produced a glucose-like effect. Luciferase assay demonstrated binding of miR-146a with FN 3'-UTR. Retinal, cardiac and renal tissues from type 1 and type 2 diabetic animals showed decreased miR-146a and increased FN and p300. Intravitreal injection of miR-146a mimic restored miR-146a expression and prevented retinal FN upregulation. Interestingly, p300 mediated histone acetylation was found to regulate miR-146a expression; whereas another reduced miRNA, miR-200b, which targets p300 was found to control p300 expression.

Conclusion: Data from these experiments demonstrated novel glucose-induced transcriptional circuitry in which histone acetylation and miRNA alterations participate in the regulating extracellular matrix protein production in diabetes. Identifying such molecular mechanisms may lead to potential RNA based treatment for diabetic complications.

Histone acetylation and miRNA alterations causing increased extracellular matrix protein production in chronic diabetic complications

B. Feng, S. Chen, S. Sen, S. Chakrabarti;
Pathology, The University of Western Ontario, London, Canada.

Background and aims: In diabetes, increased extracellular matrix protein such as fibronectin (FN) production causes well-known structural abnormalities such as basement membrane thickening, focal scarring and mesangial matrix expansion. At the transcriptional level, epigenetic mechanisms such as histone acetylation and microRNA(miRNA) alteration regulate gene expression and controls several cellular processes. We investigated such alteration in the pathogenesis of increased FN production in diabetes.

Materials and methods: Human umbilical vein endothelial cells and retinal microvascular endothelial cells were exposed to various glucose levels. FN mRNA and protein levels, histone acetylase p300 mRNA and protein levels, histone acetylation, NF- κ B activation, miRNA levels and binding specific miRNA and p300 with FN promoters were assessed. Cells were also subjected to siRNA mediated and chemical blockade of p300 and miRNA mimic or antagonist transfection. Retinal, cardiac and renal tissues from STZ-diabetic rats, db/db mice and respective controls were similarly investigated. Furthermore, retinal tissues were assessed following specific intravitreal miRNA mimic injection.

Results: In both endothelial cells, glucose caused upregulation of p300 along with augmented histone acetylation and binding of p300 and NF- κ B to FN promoter. Such acetylation caused activation of several transcription factors and increased production of FN and other vasoactive factors. In the retina, heart and kidneys of type 1 and type 2 diabetic animals, similar p300 mediated FN upregulation were seen, which were prevented by chemical blockade of p300 or intravitreal injection of p300 siRNA. In addition, glucose caused alterations of several miRNAs in the endothelial cells, including miR-146a, a FN-targeting miRNA which is of importance in inflammation. Glucose caused decrease in miR-146a expression and increased mRNA and protein

Follistatin-like 1 protects against the induction of cardiomyocyte dysfunction and insulin resistance induced by adipose tissue-derived factors

S. Greulich¹, B. Maxhera², F. Ruppe², H. Mueller¹, D. Herzfeld de Wiza¹, K. Smiris², P. Akhyari², J. Eckel¹, M. Ouwens¹;

¹Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, ²University hospital, Duesseldorf, Germany.

Background and aims: Secretory products from epicardial adipose tissue from patients with type 2 diabetes cause cardiomyocyte contractile dysfunction and insulin resistance. These detrimental effects can be ascribed, at least in part, to enhanced release of activin A from epicardial adipose tissue in type 2 diabetes mellitus. Recent proteomic approaches have identified a physiological antagonist of activin A, follistatin-like 1 (Fstl1), as novel adipokine. The present study aimed to investigate whether Fstl1 expression is altered in the intrathoracic adipose tissue depots surrounding the heart of patients with and without type 2 diabetes. Furthermore, we determined whether Fstl1 could protect against the induction of cardiomyocyte dysfunction induced by adipose tissue-derived factors.

Materials and methods: Fstl1 expression was examined in human epicardial, subcutaneous and pericardial adipose tissue biopsies collected from patients with and without type 2 diabetes undergoing open heart surgery (n=4 per group) by Western blotting. Primary rat cardiomyocytes were exposed to conditioned media generated from abdominal adipose tissue from high-fat diet-fed guinea pigs to induce cardiomyocyte dysfunction. To assess whether Fstl1 protects against these cardiopressive effects, insulin-stimulated Akt-phosphorylation and contractile function were determined in cardiomyocytes exposed to conditioned media in the presence and absence of 100 ng/ml recombinant Fstl1.

Results: Fstl1 was highly and selectively expressed in epicardial adipose tissue relative to subcutaneous and pericardial adipose tissue. Furthermore, expression of Fstl1 was reduced by 50% in epicardial adipose tissue from type 2 diabetic patients compared to non-diabetic subjects (P<0.05). In cardiomyocytes, Fstl1 enhanced insulin-induced phosphorylation of Akt by 30% (P<0.01), but had no effect on sarcomere shortening and cytosolic Ca²⁺-transients. Incubation of cardiomyocytes with conditioned media lowered insulin-induced Akt-phosphorylation by 30% (P<0.005), and induced contractile dysfunction as illustrated by reductions of 72% and 38% in sarcomere shortening and cytosolic Ca²⁺-influx after electrical stimulation, respectively (both P<0.001). Fstl1 restored the reductions in sarcomere shortening and cytosolic Ca²⁺-transients to 75% and 90%, respectively, of the response induced by control medium (both P<0.001). Finally, the abrogation of insulin-mediated Akt-phosphorylation by conditioned media was completely prevented when Fstl1 was present (P<0.001).

Conclusion: Collectively, these findings indicate that the novel adipokine Fstl1 has a cardioprotective function, and that a loss of Fstl1 in epicardial adipose tissue from type 2 diabetic patients could contribute to the development of cardiac dysfunction in type 2 diabetes mellitus.

Gender-specific differences in the effects of acute hyperglycaemia and hyperinsulinaemia on myocardial lipid content and function

M. Krebs¹, M. Krssak¹, D. Jankovic¹, C.H. Anderwald¹, S. Trattning², A. Luger¹, Y. Winhofer¹;

¹Department of Internal Medicine 3, Division of Endocrinology and Metabolism, ²Department of Internal Medicine Radiodiagnostics, Centre of Excellence High Field MR, Medical University of Vienna, Austria.

Background and aims: Women with diabetes display an increased vulnerability for heart failure compared to men. Furthermore, increased myocardial lipid content (cardiac steatosis) has been recently found to play a causal role in development of diabetic cardiomyopathy and is more pronounced in women with overt hyperglycemia compared to their male counterparts. Hence, the aim of this study was to investigate the impact of acute hyperglycemia and associated hyperinsulinemia on myocardial lipid content and left ventricular function in healthy men and women.

Materials and methods: Hyperglycemic clamps (6 hours) were performed in 18 healthy subjects (8 women, 10 men). Left ventricular dynamic parameters

and myocardial lipid content in cardiac septum were assessed by ¹H magnetic resonance imaging and breath movement navigated and ECG triggered localized ¹H single voxel MR spectroscopy, respectively; at baseline as well as during the sixth hour of hyperglycemia.

Results: Hyperglycemia (mean glucose: women: 201.4±5.3, men: 202.5±13.8 mg/dl; ns) and hyperinsulinemia (mean insulin: women: 123.5±34.9, men: 99.3±74.9 μU/ml; ns) were associated with a similar (ANOVA: ns) suppression of circulating free fatty acids (women: -93.4%, p=0.0004; men: -85.2%, p=0.002,) and a comparable (ANOVA: ns) increase in myocardial lipid content (women: +29.1%, p=0.018; men: +39%, p=0.01,) in both, men and women, in whom also age (women: 29.0±7.2, men: 27.6±3.4 years; p=ns) and Body-Mass-Index (women: 21.4±2.3, men: 23.1±2.4 kg/m²; p=ns) were comparable. However, only in women, ejection fraction significantly increased (+5.6%, p=0.0008) and end-systolic volume significantly decreased during hyperglycemia (-14.1%, p=0.0015). The increase of ejection fraction was found to be positively correlated with the rise of insulin concentrations during the clamp in the whole study group (R=0.7, p=0.002), while no impact of the infused volume on myocardial function parameters was observed.

Conclusion: In conclusion, acute hyperglycemia and hyperinsulinemia induce a comparable short term increase in myocardial lipid content in both, healthy women and men, indicating that these metabolic alterations might be directly responsible for myocardial steatosis in type 2 diabetes. However, short term changes in myocardial function (that might be related to hyperinsulinemia) were observed only in women.

1236

Effect of diabetes and hyperglycaemia on the left ventricle - does it differ with ethnicity?

C.M. Park, K. March, T. Tillin, J. Mayet, N. Chaturvedi, A.D. Hughes; International Centre for Circulatory Health, Imperial College London, UK.

Background and aims: Existence of a distinct diabetes related cardiomyopathy, and specifically, an increase in left ventricular (LV) mass as a consequence of hyperglycaemia, is controversial. In addition, the contributions of hypertension and obesity to an increase in LV mass in association with hyperglycaemia have not wholly been accounted for. Understanding how the clusters of these risk factors associated with diabetes interact on ventricular structure can be assisted by studying ethnic minority groups where risk factor clustering differs markedly. We therefore explored the relationship between hyperglycaemia with LV mass in three ethnic groups (European (E), Indo Asian (IA) and African Caribbean (Afc) using both 2D and real time 3D echocardiography.

Materials and methods: A population based sample of 1,277 men and women (608 E, 462 IA and 207 Afc) aged 58-86 years underwent 2D echocardiography (iE33, Philips). LV mass was calculated from the parasternal long axis view using diastolic wall thickness and cavity diameter measures. In addition, 726 of these participants (389 E, 239 IA and 98 Afc) underwent real time 3D echocardiography. 3D full volume sets were acquired from the apical 4 chamber view with a matrix array transducer and LV mass was measured directly offline (Philips Qlab 7.0). Both 2D and 3D LV mass measures were indexed to height^{2.7} (g/m^{2.7}). Height, weight and blood pressure were measured and an OGTT performed.

Results: Using conventional 2D measures, LV mass increased with advancing glucose intolerance in all ethnic groups. People with diabetes had greater LV mass than normoglycaemic individuals by +5.1g/m^{2.7} in E, +5.2g/m^{2.7} in IA and +5.2g/m^{2.7} in Afc. Within each ethnic group LV mass/height^{2.7} was strongly associated with age, BMI, systolic blood pressure, fasting blood glucose and HbA_{1c} (table). However the association of glucose and HbA_{1c} did not remain significant after additional adjustment for BMI (table). BMI also accounted for the ethnic differences in LV mass, for example, BMI in normoglycaemic individuals was largest in Afc (28.8±0.6kg/m²), followed by E (26.8±0.2kg/m²) and was smallest in IA (25.8±0.3kg/m²). 3D echocardiography in people without known diabetes also showed a significant association between LV mass/height^{2.7} and glucose (β=0.7±0.3 p=0.025) that was abolished following adjustment for BMI (β=0.12±0.3 p=0.69).

Conclusions: Diabetes and hyperglycaemia are associated with an increase in LV mass. The association between LV mass and hyperglycaemia was similar by ethnic group. Within ethnic groups, BMI accounted for the association between hyperglycaemia and LV mass. BMI also accounted for the absolute ethnic differences in LV mass by glucose tolerance category.

2D LV mass/height ^{2.7}	European (n=608)			Indo Asian (n=462)			African Caribbea n (207)

Evaluation of vascular inflammation using FDG-PET in primary coronary heart disease prevention

H. Hong, H. Choi, S. Yang, C. Eun, M. Cho, H. Yoo, H. Kim, J. Seo, N. Kim, S. Kim, K. Choi, S. Baik, D. Choi, Y. Kim;
Division of Endocrinology and Metabolism, Korea University College of Medicine, Seoul, Republic of Korea.

Background and aims: To evaluate vascular inflammation by ¹⁸F-fluorodeoxyglucose (FDG) positron emission tomography (PET) CT, which reflects vulnerable atherosclerotic plaque in primary coronary heart disease prevention.

Materials and methods: We measured high-sensitivity C-reactive protein (hsCRP) and traditional cardiovascular risk factors in 142 healthy subjects. To assess the vascular influence of hsCRP on each Framingham risk score (FRS) category, we compared carotid intima-media thickness (CIMT), brachial-ankle pulse wave velocity (baPWV), and vascular inflammation, which was represented as the target-to-background ratio (TBR) measured using FDG-PET/CT.

Results: In both intermediate (10%–20%) and low (<10%) FRS categories, mean TBR values in subjects with higher hsCRP levels (≥2 mg/L) were significantly increased compared to those with lower hsCRP levels (<2 mg/L) (P = 0.001, P < 0.001, respectively). However, baPWV and CIMT values did not significantly differ according to hsCRP levels in the same FRS categories. Mean TBR levels positively correlated with FRS, body mass index (BMI), waist circumference, LDL-cholesterol, triglyceride, creatinine, glucose, and hsCRP, whereas negatively correlated with HDL-cholesterol. Multiple stepwise regression analyses showed that hsCRP, LDL-cholesterol, BMI, and insulin resistance were independently associated with mean TBR values (R² = 0.414).

Conclusion: In both intermediate and low FRS risk groups, vascular inflammation measured using FDG-PET/CT was increased in individuals with higher hsCRP levels compared to those with lower hsCRP.

The influence of metabolic disorders in children with diabetes mellitus type 1 on changes of QT interval

G. Meraai, A. Solntsava;

First Department of childhood diseases, Belarussian State Medical University, Minsk, Belarus.

Diabetes Mellitus disturbs cellular metabolism of all organs and tissues, including myocardium.

Research: to evaluate values of intervals QT and QTc in children with Diabetes Mellitus type 1 (DM1) and to reveal interrelation of the given changes with the duration of disease, age, sex, indices of metabolic control.

Materials and methods: QT and QTc were evaluated on ECG in 178 children with DM1 (middle age 13.44±0.29 years, duration of disease 5.72±0.28 years) and in 60 sex- and age-matched healthy children. Level of HbA_{1c} in children with DM1 made up 9.82±0.18% (N<6.2%; P<0.001).

Results: Increases of values of intervals QT and QTc are characteristic to children with DM1 in comparison with control group (364.56±2.65 ms and 421.39±3.1 ms, 352.97±15.1 ms and 392.73±13.0 ms respectively, P<0.0015). It is established that values of QTc in girls with DM1 are higher than in boys (428.07±4.51 ms versus 413.6±4.08 ms, P<0.0025). 17.71% of girls and 13.41% of boys with DM1 have autoimmune thyroiditis (the percent of children with values of QTc>440 ms is high in this group). Levels of thyroid-stimulating hormone (TSH) and thyroperoxidase antibodies (Anti-TPO) are different before and after manifestation of Diabetes Mellitus type 1 (4.21±0.44 μIU/ml and 83.13±13.45 IU/ml, 5.52±1.06 μIU/ml and 251.62±32.66 IU/ml respectively, P<0.0002) At the same time values of HbA_{1c} are higher in boys than in girls (10.4±0.3% and 9.35±0.2% respectively, P<0.002). The difference in pulse rate between girls and boys is insignificant for the group studied. Connection of QTc with age (r=0.338, P<0.00001) and level of HbA_{1c} (r=0.37, P<0.0001) was established. Feedback connection of QT with pulse rate was revealed (r=-0.48, P<0.005). There were no reliable correlations of QTc with Body Mass Index, level of cholesterol, duration of the disease and values of systolic and diastolic blood pressure.

Conclusions: The increase of QT and QTc is noticed in children with DM1. Age, level of glycemic and pulse rate are the factors defining values of QTc. In girls QTc has higher values more often than in boys. Intervals QTc>440 ms are found more often in children with DM1 and autoimmune thyroiditis.

1239

Coronary response to an increased oxygen demand in asymptomatic type 2 diabetic patients: a new non-invasive approach

M. Nguyen¹, I. Pham², A. Nitenberg², P. Valensi¹, E. Cosson¹;

¹Department of Endocrinology- Diabetology-Nutrition, Jean Verdier Hospital, AP-HP, CRNH-IdF, Paris-Nord University, ²Department of Physiology, Jean Verdier Hospital, AP-HP, EA 23-63, Paris-Nord University, UFR SMBH, Bobigny, Bondy, France.

Rationale and aims: The aim of the present study was to assess, using for the first time a non invasive method, the coronary response to physiological increase in myocardial demand, and its relationship with silent myocardial ischemia (SMI) and silent coronary stenoses (CS) in type 2 diabetic patients (T2D).

Materials and method: A total of 118 asymptomatic T2D for 15.0±7.4 years (72 males, 61.1±8.2 years, BMI 30.6±5.4 kg/m²) without a cardiac history and fulfilling the criteria of the French guidelines for SMI screening were prospectively screened for SMI, defined as an abnormal stress myocardial scintigraphy and/or stress echocardiography. A coronary angiography was performed in those with SMI. The distal inter-ventricular anterior coronary velocity (CV) was measured by trans-thoracic echo-doppler (3-7MHz) before and after cold pressure test (CPT). CPT was also performed in 30 overweighted or obese non diabetic subject (OS) and 25 control subjects < 40 years.

Results: Thirty-five of T2D had SMI, and 15 of them CS. CV during CPT could be measured in 56% T2D, 37% OS and 64% controls. Changes after CPT/baseline in DP (rate-pressure product) (43±034, 36±27 and 32±19% increase) and in CV (30±26, 21±34 and 17±10% increase) did not significantly differ in the 3 groups. CV changes correlated with DP changes in control (r=0.58, p<0.05), OS (r=0.75, p<0.01), T2D without CS (r=0.56, p<0.0001) but not in those with CS. In T2D, SMI was associated with higher increase in CV after CPT (SMI- 21±22, SMI+CS- 36±28 and SMI+CS+ 39±26% increase, p=0.03) despite similar DP increase, with male gender, BMI, diabetic nephropathy, triglycerides and haptoglobine (p=0.02 to 0.05). In multivariate analysis including these factors, SMI was only associated with CV changes (per 10% increase OR: 1.3 [1.1–1.5], p<0.05).

Conclusion: 1) Non invasive study of the coronary reactivity is feasible by trans-thoracic echography-doppler with a lower feasibility in OS, 2) the coronary response to an increase in myocardial oxygen demand is impaired in T2D patients with silent CS, 3) T2D with SMI in particular those with CS have higher increase in coronary velocity after CPT, probably due to the lack of coronary dilation related to endothelial dysfunction.

Co-morbidity burden and incident hypoglycaemia in patients with type 2 diabetes and heart failure: insight from DiaRegis

D. Tschoepe¹, C. Binz², P. Bramlage³, M. Krekler², T. Plate⁴, E. Deeg⁵, A.K. Gitt⁵; ¹Herz- und Diabeteszentrum Nordrhein-Westfalen, Bad Oeynhausen, ²Bristol Myers Squibb, München, ³Institut für Kardiologische Pharmakologie und Epidemiologie, Mahlow, ⁴AstraZeneca, Wedel, ⁵Institut für Herzinfarktforschung Ludwigshafen an der Universität Heidelberg, Ludwigshafen, Germany.

Background and aims: Data on co-morbidity burden and hypoglycaemia in particular in patients with type 2 diabetes and heart failure (HF) are scarce.

Materials and methods: DiaRegis is a prospective registry in type-2 diabetic patients insufficiently controlled on oral mono- or dual antidiabetic therapy. Patients with or without anamnestic HF were compared.

Results: For 3,746 patients, 9.9% of which had HF, data were available. Median age was 65.9 years, 46.8% were female. HF patients were older (73.1 vs. 64.7 years; $p < 0.0001$) and frequently had co-morbid disease such as hypertension (95.4 vs. 83.1%; $p < 0.0001$), coronary heart disease (52.9 vs. 13.8%; $p < 0.0001$), prior stroke/TIA (9.5 vs. 4.1%; $p < 0.0001$), peripheral arterial disease (15.6 vs. 4.9%; $p < 0.0001$) and autonomous neuropathy (7.2 vs. 2.9%; $p < 0.0001$). Prior to enrolment into the registry, they received less metformin (Met) and more sulfonylureas (SU) in monotherapy compared to patients without HF, both drugs are known to interfere with the incidence of HF. After enrolment insulin treatment was initiated in 21.4% patients with HF versus 16.6% patients without HF ($p < 0.05$). Incident stroke/TIA, angina pectoris, percutaneous coronary intervention, and peripheral angioplasty were significantly increased in patients with HF after a 6 months follow-up. Furthermore, hypoglycaemic events were 50% more frequent in patients with HF in the 12 months preceding enrolment and at the 6 months follow-up.

Conclusion: Patients with type 2 diabetes and HF show a substantial co-morbidity and seem to be more prone to develop hypoglycaemia.

	Heart failure (n=370)	No heart failure (n=3386)	p-value
Metformin enrolment / after therapy change at baseline (%)	76.8 / 74.3	85.0 / 85.8	<0.0001 / <0.0001

Lower incidence of myocardial infarction in type 2 diabetic patients with polyneuropathy who were treated with an aldose reductase inhibitor (epalrestat): a retrospective study

T. Kajiwar¹, Y. Kaneko¹, I. Hikichi², M. Ishii¹, Y. Narigawasa³, K. Sato⁴, F. Fujiwara¹, H. Taneichi¹, N. Takebe¹, K. Takahashi¹, J. Satoh¹, Iwate Diabetic Neuropathy Study Group;

¹Division of Diabetes and Metabolism, Department of Internal Medicine, Iwate Medical University School of Medicine, Morioka, ²Department of Diabetes and Metabolism, Morioka City Hospital, Morioka, ³Sakurano Naika Clinic, Kitakami, ⁴Department of Internal Medicine, General Hanamaki Hospital, Japan.

Background and aims: Epalrestat, an aldose reductase inhibitor, is clinically available only in Japan, and has been being used since 1992 for treatment of diabetic polyneuropathy (DP). Epalrestat inhibits enhanced aldose reductase activity, reduces accumulation of sorbitol in tissues, and suppresses progres-

sion of DP in diabetic animals and human. Furthermore, epalrestat has anti-oxidant activity, and it has been indicated that epalrestat has a protective effect on arteriosclerosis and ischemia/reperfusion injury. These imply that epalrestat may have a protective effect against myocardial infarction (MI) in diabetic patients. Therefore, we retrospectively studied incidence of MI in patients with type 2 diabetes with DP, who were treated or untreated with epalrestat for more than 5 years, and compared the incidence between the two groups.

Materials and methods: Subjects were patients with type 2 diabetes and DP, which was defined by the practical and simple diagnostic criteria proposed by the Diabetic Neuropathy Study Group in Japan. Diabetic patients were diagnosed as having DP, when they had two of three items: (1) sensory symptoms considered to be due to DP, (2) bilaterally decreased or absent ankle reflex and (3) decreased vibratory sensation in bilateral medial malleoli, and when other neuropathy than DP could be excluded. There were no difference in age, sex, duration of diabetes, and HbA1c between the patients treated with epalrestat (150 mg/day) (N = 111) and without epalrestat (non-epalrestat) (N = 64).

Results: The incidence of MI was 3.5 (per 1000 x person x year) in the epalrestat group treated with epalrestat for more than 5 years, whereas it was 12.8 (per 1000 x person x year) in the non-epalrestat group. On the other hand, there was no difference in the incidence of cerebrovascular diseases in the two groups (8.9 vs. 9.3). The Kaplan-Meier analysis indicates that there was a significant difference in the incidence of MI (Logrank test, $p = 0.019$), but not cerebrovascular diseases (Logrank test, $p = 0.919$), between the two groups. Prevalence of DP, retinopathy, and nephropathy was 100% vs. 100% (NS), 57.7% vs. 59.4% (NS), and 49.5% vs. 82.8% ($P < 0.01$) in the epalrestat and the non-epalrestat group, respectively. There were significant differences in proportion of patients taking oral hypoglycemic agents (98.2% vs. 56.3%, $P < 0.01$) and anti-hypertensive drugs (60.4% vs. 31.3%, $P < 0.01$) between the epalrestat and the non-epalrestat group, whereas no differences in that of patients receiving insulin (55.0% vs. 56.3%, NS) and taking cholesterol-lowering drugs (45.9% vs. 31.3%, NS) in the two groups. A multiple regression analysis is in progress to reveal an independent association of the use of epalrestat with low incidence of MI.

Conclusion: The results imply that epalrestat may have protective effect against MI in patients with type 2 diabetes and PN. It will be worthy to evaluate a beneficial effect of epalrestat on prevention of MI in diabetic patients by a randomised prospective clinical study.

1242

Metformin, Vit B₁₂ deficiency and silent myocardial ischaemia in type 2 diabetic patients

G. Gastaldi¹, T. Mura², A. Sultan¹, C. Piot³, J.-P. Cristol⁴, E.M. Renard¹, F. Galtier², A. Avignon¹;

¹Endocrinology, diabetology and metabolism, CHU Lapeyronie, ²Clinical Investigation Center, CHU Saint-Eloi, ³Cardiology, CHU Lapeyronie, ⁴Biochemistry Department, CHU Lapeyronie, Montpellier, France.

Objective: To investigate the relationship between metformine-associated vitamin B12 (Vit B12) deficiency and hematological and cardiovascular morbidity in type 2 diabetes.

Research design and methods: 795 patients with type 2 diabetes (57.6 % male, 62.3 % metformin-treated, mean HbA1c 8.3 ± 1.5 %) with > 1 cardiovascular risk factor were evaluated in this retrospective cross-sectional study. Their main characteristics are shown in the table. They all underwent silent myocardial ischemia (SMI) screening using dipyridamole combined with exercise myocardial perfusion imaging (MPI). SMI was defined as positive MPI (mean activity < 70% of the maximal myocardium activity in ≥ 3 of 20 segments) or positive exercise electrocardiogram (ECG) (horizontal or descending ST segment depression > 1 mm). Biological parameters were evaluated in fasting conditions on the same day as SMI screening. Glomerular filtration rate (GFR) was estimated by the Cockcroft and Gault formula. Vit B12 deficiency and hyperhomocysteinemia were defined as values < 150 pmol/l and > 15 μ mol/l, respectively. Adjustments were made using multivariate logistic regressions.

Results: Crude prevalences of Vit B12 deficiency were 12.5 % in metformin-treated patients and 6.1 in non-metformin-treated patients ($p < 0.01$). After adjustments for tobacco use, gender, BMI, age, GFR, insulin use and presence of hypertension, metformin use was associated with a significant risk of Vit B12 deficiency (OR 3.22; 95% CI = 1.44- 7.19). In metformin-treated population, Vit B12 deficient were older (66.7 ± 7.7 vs 60.1 ± 8.8 , $p < 0.05$), with a longer duration of diabetes (16.7 ± 11.1 vs 12.9 ± 9.1 , $p < 0.001$) and a higher AST/ALT ratio (1.14 ± 0.47 vs 0.94 ± 0.35 , $p < 0.001$). Metformin-associated Vit B12

deficiency was not associated with a higher prevalence of hyperhomocysteinaemia (crude values 52.6 vs 34.6 %, OR 1.81 [95% CI = 0.62– 5.26] adjusted for age, nephropathy, AST/ALT ratio, erythrocytes folates) or with a higher risk of SMI (crude values 13.3 vs 22.6 %, OR 0.41 [95% CI = 0.14– 1.16] adjusted for age, gender, BMI, nephropathy, LDL-cholesterol, tobacco use, presence of hypertension, hs-CRP). There was no association between Vit B12 deficiency and anemia (24% vs 20% $p = 0.51$) or macrocytosis (4.7% vs 2.5% $p = 0.35$).

Conclusion: This cross-sectional study confirms the association between metformin and Vit B12 deficiency. In our series, metformine-associated Vit B12 deficiency is associated neither with an increased prevalence of silent myocardial infarction nor with hematological abnormalities.

two subgroups. Similarly, comparing patients in subgroup 2 to the ones in subgroup 3 there were no significant differences found in the echocardiography parameters measured neither at the beginning of the study nor after 3 years of follow up. Patients in subgroup 2 had no significant differences in echocardiography parameters found during the 3 years of observation.

Conclusion: The longer existence of glucose metabolism disorders in patients after kidney transplantation the worse are the outcomes of some of the diastolic myocardial function parameters (E/A wave ratio, IVRT) and paradoxically the thickness of left ventricular posterior wall and septum improves with time. Further, larger studies should provide verification of this finding and clues on its nature.

Comparison of non-metformin-treated and metformin-treated patients

	All patients (N = 798)	Non-metformin-treated (N = 301)	Metformin-treated (N = 497)	p

Glucose metabolism disorders and echocardiography parameters in patients after kidney transplantation during 3-years of follow up

K. Nabrdalik, A. Witkowska, J. Żywiec, P. Adamczyk, A. Strózik, W. Grzeszczak, J. Gumprecht;
Medical University of Silesia, Zabrze, Poland.

Background and aims: Glucose metabolism disorders are one of the diseases that accelerates arteriosclerosis. The study aimed to assess if glucose metabolism disorders in patients after kidney transplantation are associated with worsening of heart function in echocardiography examination.

Materials and methods: This was a 3-year prospective, observational study in the group of 83 patients (53 men and 31 women; aged 45.6 ± 12.1 years) in mean 5.3 ± 2.3 years after kidney transplantation with chronic graft dysfunction (GFR 49.3 ± 19 ml/min/1.73m²) receiving the same immunosuppressive therapy. The echocardiography parameters, kidney function (GFR) and diabetic status (OGTT, HbA1c, postprandial glycaemia) were monitored once a year and compared between the groups of patients with and without glucose metabolism disorders with adjustment for age, sex, BMI, smoking, hypertension, and lipid status (analysis of covariance).

Results: At the beginning of the study there were 15 patients with glucose metabolism disorders of mean duration 5.0 ± 3.9 years (subgroup 1): diabetes type 2 ($n=12$), impaired fasting glucose (IFG, $n=2$) and impaired glucose tolerance (IGT, $n=1$). After 3 years of follow up there were 14 new cases of glucose metabolism disorders revealed (subgroup 2): post-transplant diabetes mellitus ($n=6$), IFG ($n=5$) and IGT ($n=3$). There were 54 patients without glucose metabolism disorders (subgroup 3). Patients in subgroup 1 comparing to the ones in subgroup 2 had significantly worse E/A wave ratio after 3 years of follow up (0.7 ± 0.2 vs 1.18 ± 0.4 , $P=0.010$) while at the beginning of the study no difference in diastolic heart function parameters were found. At the beginning of the study there was posterior wall diastolic diameter (PWDd) significantly thicker in subgroup 1 comparing to subgroup 2 (13.9 ± 0.9 mm vs 12.3 ± 0.4 mm, $P=0.047$) but the difference paradoxically became not significant after 3 years of follow up. Comparing the echocardiography measurements among patients in subgroup 1 there was difference in diastolic heart function found where IVRT became significantly longer after 3 years of follow up comparing to the beginning of the study (110.96 ± 17.5 msec vs 101.7 ± 15.1 msec, $P=0.047$). Comparing patients in subgroup 1 to the ones in subgroup 3 there was PWDd (13.9 ± 0.9 mm vs 12.6 ± 0.5 mm, $P=0.029$) and intraventricular septum diastolic diameter (14.2 ± 0.8 mm vs 12.6 ± 0.4 mm, $p=0.020$) significantly thicker at the beginning of observation but after 3 years of follow up there was no significant differences in relation to left ventricular wall or septum thickness between the

Blood glucose fluctuation-induced apoptosis in myocardium and aorta through oxidative stress and chronic inflammation

P. Han, W. Zhang, S. Zhao, Y. Li, N. Wu, Y. Zhang, B. He;
Department of Endocrinology, Shengjing Hospital of China Medical University, Shenyang, China.

Background and aims: Patients with diabetes are at increased risk of cardiovascular disease. Recent studies have shown that the development of cardiovascular complications in diabetes is not only associated with persistent high blood glucose level, but also closely associated with the fluctuations of blood glucose. Most previous studies of the effect of blood glucose fluctuation on vascular endothelial cells are done in vitro, few studies have reported the effects of intermittent hyperglycemia on the apoptosis of myocardium and aorta in vivo. Therefore, we established a model in vivo of blood glucose fluctuation by intermittent high glucose infusion in Wistar rats. Co-infusion with N-acetyl cysteine (NAC, an antioxidant) was designed to investigate the effects of NAC on apoptosis of myocardium and aorta, and to explore its potential mechanism of blood glucose fluctuation on these tissues in vivo.

Materials and methods: Cannulated rats (n=6-8/group) were infused for 48h intravenously with (1) saline(SAL), or (2) 50% glucose continuously, maintaining persistent high blood glucose level at 20 ± 0.5 mmol(PHG), or (3) 50% glucose intermittently, maintaining blood glucose level at 5.5 ± 0.5 mmol for 1h, then at 20 ± 0.5 mmol for 1h, changing the level of blood glucose alternatively(IBG), or (4) IBG plus NAC, $0.35 \text{ mg} \cdot \text{kg}^{-1} \cdot \text{min}^{-1}$ (IBG+NAC). Oxidative stress measured as the concentration of malondialdehyde (MDA), nitric oxide (NO) and glutathione peroxidase (GSH-PX) activity in serum and cardiac and aortic tissues was analyzed using colorimetric method. We also evaluated levels of nuclear factor- κ B (NF- κ B), and intercellular adhesion molecule-1 (ICAM-1) with immunohistochemistry, the expression of IL-6 mRNA and TNF- α mRNA with RT-PCR, the levels of IKK β , Bax and Bcl-2 with western blot, and apoptosis with TUNEL in myocardium and aorta.

Results: The results showed that both IBG and PHG groups had higher levels of oxidative, inflammatory markers and apoptotic proteins in myocardium and aorta than control group ($P < 0.05$). In myocardium and aorta, the levels of oxidative markers (MDA, NO) were significantly higher, while GSH-PX activity was lower in IBG group than those in PHG and control groups ($P < 0.05$). Compared with PHG and control groups, the levels of inflammatory markers (NF- κ B, IKK β , ICAM-1, TNF- α mRNA and IL-6 mRNA) and pro-apoptotic protein (Bax) in IBG group were increased remarkably ($P < 0.05$), while the anti-apoptotic protein (Bcl-2) was lower ($P < 0.05$). The number of apoptotic cells of myocardium and aorta was higher in IBG group ($P < 0.05$). Co-infusion with NAC prevented the elevation oxidative and inflammatory markers in IBG group. NAC also inhibited the elevation of Bax and the decrease in Bcl-2, meanwhile, abolished apoptosis of myocardial and aortic cells in IBG group.

Conclusion: Blood glucose fluctuations induced more severe oxidative stress, chronic inflammation and apoptosis in myocardium and aorta than persistent high blood glucose. NAC, as an antioxidant, prevented apoptosis of myocardium and aorta induced by blood glucose fluctuation in vivo. This effect of NAC might due to its antioxidative and anti-inflammatory properties.

Postprandial phase fluctuations can trigger the coagulation cascade

K. Onbasi, B. Efe, O. Celer;
Endocrinology and Metabolism, Eskisehir Osmangazi University, Turkey.

Background and aims: Cardiovascular Diseases (CVD) are the most common causes of mortality and morbidity among patients with type 2 diabetes. Poorly controlled postprandial hyperglycemia contributes to the development of atherosclerosis. Fluctuations of the postprandial glucose levels bring changes in the coagulation system and propensity to thrombosis. Our aim was to determine the change of plasma coagulation parameters like D-Dimer, β -Thromboglobulin (β -TG), P-Selectin, Plasminogen activator inhibitor-1 (PAI-1), Prothrombin fragments 1-2 (PTF 1-2) in comparison to the fasting

levels in 15 healthy controls and type 2 diabetic patients under treatment of various agents (metformin, insulin secretagog agents and insulin).

Materials and methods: Blood samples were withdrawn after 12 h of fasting (min 0) and following breakfast composed of foods proper for each person, at 60th, 90th and 120th minutes. Fasting and 60th, 90th, and 120th minute measurements of glucose, insulin, triglyceride, D-Dimer, β -TG, P-Selectin, PAI-1, PTF 1-2 had been performed. HA1C and fructosamine were measured also.

Results: Some coagulation parameters tend to be changed at the postprandial phase in diabetics as well as in healthy controls. At the postprandial phase, PAI-1 increased and β -TG decreased significantly in both healthy controls and in all groups of diabetics. The fasting levels of fibrinogen, D-Dimer and P-Selectin were high in diabetics in comparison to healthy controls. An increase in the levels of P-Selectin, PAI-1 and PTF 1-2 at the postprandial phase was observed in healthy persons. Patients receiving insulin secretagog therapy showed an increase in the postprandial levels of PAI-1 like healthy controls. Patients receiving metformin showed an increase in the postprandial levels of PAI-1 and PTF 1-2. Postprandial phase changes in patients receiving metformin were similar to healthy controls. Poorly controlled, older patients with longer diabetes duration had been receiving insulin and these mentioned patients' levels of fibrinogen, D-Dimer and P-Selectin were high in the fasting state and showed an increase in PAI-1 at the postprandial phase. Postprandial levels of PTF 1-2 and D-Dimer were high in insulin treated patients. Levels of fibrinogen and D-Dimer were higher in patients with retinopathy. HA1C and fructosamine were correlated with the coagulation parameters like P-selectin, PAI-1 and PTF 1-2 levels. Correlations showed us that not only postprandial hyperglycemia but also accompanying diabetes, obesity, dyslipidemia and hypertension can aggravate this coagulation tendency at the postprandial phase.

Conclusion: Postprandial phase changes can trigger postprandial coagulation cascade in diabetics as well as healthy persons.

Analogue versus human insulin regimen improves postmeal glucose and cardiac function in type 2 diabetes patients with intensive conventional insulin therapy

H. von Bibra¹, I. Walther¹, T. Siegmund¹, T. Schuster², A. Pfützner³, P.-M. Schumm-Draeger¹;

¹Endocrinology, Academic Hospital Bogenhausen, München, ²IMSE, Technical University of Munich, ³IKFE Institute, Mainz, Germany.

Background and aims: Fast acting analogue insulins lower postprandial (pp) glucose levels more effectively also in type 2 diabetes (T2D) compared to regular human insulin. However, it is not clear whether this therapy is also able to improve myocardial dysfunction in T2D. This prospective, randomized, open long-term study tested the hypothesis, that intensive conventional insulin therapy (ICT) with analogue insulins (AI) vs. human insulins (HI) improves pp glucose control and cardiac function.

Materials and methods: For 36 months, 109 T2D patients were seen every three months to adapt ICT treatment for the targets fasting glucose ≤ 110 mg/dl and pp glucose ≤ 150 mg/dl in the two groups: AI (insulin detemir and insulin aspart, n=61) and HI (NPH-insulin and regular human insulin, n=48). Diastolic myocardial function (E') was assessed by pulsed tissue Doppler before and two hours after a standardized meal, a pure carbohydrate continental type of breakfast (48g carbohydrates). Intact proinsulin was determined in representative subgroups of AI (n=36) and HI (n=33). Both groups were comparable with regard to demographics, cardiac function and metabolic control at baseline. Data were analyzed by multiple imputation technique.

Results: After 36 months, pp serum glucose was reduced by 20 ± 64 mg/dl ($p < 0.03$) in AI but increased by 4 ± 56 mg/dl (n.s.) in HI (AI vs. HI $p < 0.05$). Fasting serum glucose was reduced by 12 ± 53 mg/dl in AI ($p < 0.096$) and by 19 ± 44 mg/dl in HI ($p < 0.01$). HbA1c decreased in AI from 7.3 ± 1.7 to $6.7 \pm 0.8\%$, $p < 0.02$) and in HI (7.7 ± 1.8 to $6.5 \pm 0.8\%$, $p < 0.001$). In AI, E' increased from 7.8 ± 1.4 to 8.3 ± 1.7 cm/s ($p < 0.02$) in the fasting state and pp from 7.6 ± 1.6 to 8.3 ± 1.7 cm/s ($p < 0.002$). In HI, there was no change of E' fasting (8.2 ± 1.7 to 8.1 ± 1.8 cm/s) or pp. Intact proinsulin was significantly more reduced in AI compared to the increase in HI ($-0.7 [-2.3 - 0.8]$ vs. $0.3 [-0.9 - 2.7]$ pmol/l, $p < 0.049$).

Conclusion: After 36 months, ICT with AI significantly improved pp glucose control associated with an improved insulin resistance and cardiac function compared to ICT with HI. Given the prognostic relevance of diastolic myocardial dysfunction in T2D, this association should be taken into consideration when selecting an insulin regimen for people with T2D.

Hypoglycaemia and cardiovascular disease: results from the Catalan National Health Service registry on insulin pump therapyI. Conget¹, J. López², C. Castell³, M. Giménez¹¹Diabetes Unit, Endocrinology Department, Hospital Clínic i Universitari/IDIBAPS, Barcelona, ²Endocrinology and Nutrition Department, University Hospital of Leon, ³Health Department, Catalan Health Service, Generalitat de Catalunya, Barcelona, Spain.

Background and aims: The concept that repeated hypoglycaemia could be a potential aggravating factor for atherosclerotic processes in diabetes (type 1 and type 2, T1D) has recently been suggested. Recurrent severe hypoglycaemic episodes and hypoglycaemia unawareness are usually considered indications for continuous subcutaneous insulin infusion (CSII) therapy. The aim of our study was to evaluate the prevalence of cardiovascular disease (CVD) in patients with and without history of repeated hypoglycaemia at the time of starting CSII therapy.

Materials and methods: The database from the Catalan National Health Service registry on CSII therapy (1990–2010) was analysed. It included 1550 T1D patients at entry and prior starting CSII (Aged 34 ± 12 years; 69% women, duration of diabetes 16 ± 9 years; HbA_{1c} 8.2 ± 1.3 %; body mass index (BMI) 24 ± 5 kg/m²). The percentage of patients in which the main indication for CSII included repeated hypoglycaemia, as well as, the proportion of patients with any severe episode of hypoglycaemia the year before was obtained. The prevalence of any form of CVD including coronary heart disease, peripheral arterial disease (including amputations) and cerebrovascular disease was evaluated. We compared the results obtained in the Group of patients with (Hypo Group) and without (Control Group) history of severe episodes of hypoglycaemia the year before entry in the registry. In addition, age, gender, duration of diabetes, BMI, HbA_{1c} , presence of any form of microvascular complication, antihypertensive and lipid treatment were also evaluated. A multivariate analysis was performed using a multiple logistic regression including CVD as dependent variable and age, gender, duration of diabetes, BMI, HbA_{1c} and the presence of severe episodes of hypoglycaemia the year before as independent variables.

Results: Repeated hypoglycaemia was an indication for starting CSII in 14.9% of patients whereas history of severe hypoglycaemia the previous year was present in 34.6% of the cases. Considering the total cohort, any manifestation of CVD was already present in the 4.7% of subjects. In Hypo Group (aged 36 ± 12 years; diabetes duration 17 ± 10 years; HbA_{1c} 8.1 ± 1.3 %; BMI 23 ± 3 kg/m²) the percentage of patients with CVD was significantly higher (6.9 %) than in the control group (3.9 %; $p < 0.05$) (aged 33 ± 12 years; diabetes duration 15 ± 9 years; HbA_{1c} 8.2 ± 1.2 %; BMI 23 ± 3 kg/m²). Previous differences in CVD percentages were not influenced by age, duration of disease, gender and the presence of antihypertensive treatment. In subjects without lipid treatment, CVD was more prevalent in Hypo group. In the multivariate analysis, age, duration of disease and gender were independent risk factors for CVD. When all age and duration of diabetes were removed from the analysis, the presence of severe hypoglycaemia emerged as an independent risk factor for CVD (β st 1.820; $p < 0.05$).

Conclusion: Data obtained from the analysis of a national registry on insulin pump therapy points to a higher prevalence of CVD in subjects with history of repeated severe hypoglycaemia. Due to the intrinsic limitations of this type of study, repeated hypoglycaemia cannot be blamed as an independent risk factor for CVD.

1248

Systematic evaluation of the influence of hyperglycaemia on diastolic myocardial functionU. Hoevelmann¹, L. Hermanski¹, L. Nosek¹, C. Kapitza¹, T. Heise¹, L. Heinemann¹, T. Jax^{1,2}¹Profil Institut für Stoffwechselforschung, Neuss, ²Herzzentrum Wuppertal, Universität Witten/ Herdecke, Germany.

Background and aims: Diabetes mellitus is associated with a high cardiovascular risk. There is epidemiological evidence that postprandial hyperglycemia is an important risk factor for cardiovascular events. Recent clinical-experimental studies in patients with diabetes showed that during hyperglycemia endothelial function is impaired, as is myocardial blood flow. The latter effect can be reversed by insulin in diabetic patients. The question remains, whether hyperglycemia also impairs myocardial function and whether this is

dependent of preexisting diabetes, or hyperinsulinemia. The aim of this study is therefore to evaluate the differential effects of isolated hyperglycemia in healthy and diabetic subjects on myocardial function.

Materials and methods: A total of 12 subjects were studied (4 healthy (H), 4 type 2 (T2) and 4 type 1 (T1) diabetic subjects). Each subject underwent a stepwise increase from eu- to hyperglycemic glucose levels by means of a glucose clamp for 8–12 hours (Run in with 90 mg/dl, 180, 300, and 300 mg/dl with 2.5 mU/kg/min Insulin i.v.). Repeated echocardiographic assessments of cardiac function were done at baseline and during the course of the clamp.

Results: At baseline E' (tissue Doppler) differed significantly between groups, as expected (H 13.6 ± 2.6 , T1 10.5 ± 2.9 and T2 7.6 ± 1.6 cm/s, $p < 0.05$). With increasing hyperglycemia (300mg/dl) and hyperinsulinemia for 60 min only E' in healthy subjects improved, in diabetics E' was stable at baseline levels. E/A was significantly different between H and T2 at baseline (0.94 vs. 1.46, $p < 0.05$), only T2 showed an improvement (1.2 vs. 0.94, which although not significant, could be judged as pseudonormalisation, but fell below baseline levels with additional insulin. To exclude volume effects, E/E' as a measure of LVEDP did not show relevant changes.

Conclusion: Unexpectedly hyperglycemia did not reduce but rather improve diastolic function in healthy subjects (E'), this effect was not apparent in diabetics. Pseudonormalisation was deteriorated by insulin in type 2 diabetics. Thus, healthy hearts may be better able to translate excessive glucose into cardiac work, and diabetic hearts may have lost the ability to utilize glucose, a mechanism that may not be dependent on insulin resistance but rather directly related to intracellular myocytic glucose metabolism.

Muscular perfusion and mitochondrial oxidative activity in type 2 diabetic patients according to glycaemic control and microangiopathic complicationsS. Chiheb¹, S. Duteil², E. Cosson¹, C. Wary², J. Pariès¹, P. Carlier², P. Valensi¹¹Department of Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital, AP-HP, CNRH-IdF, Paris-Nord University, Bondy, ²Institut of Myology, NMR Laboratory, F-75651, CEA, I2BM, MIRCen, IdM NMR Laboratory, UPMC University, Paris, France.

Background and aims: The aim of the study was to investigate muscle perfusion and energy metabolism in type 2 diabetic patients and to determine the respective role and interactions of chronic hyperglycaemia and microangiopathy on these alterations.

Materials and methods: We examined 96 type 2 diabetic patients distributed into 3 groups: ≤ 1 microangiopathic complication and $HbA_{1c} > 9\%$ (D1 group: $n=16$) or $HbA_{1c} < 7\%$ (D2 group: $n=56$); > 2 microangiopathic complications (D3 group: $n=24$); and 36 gender- and body mass index-matched controls (group C). Multiparametric functional Nuclear Magnetic Resonance (mpf-NMR) was performed to investigate muscular perfusion (arterial spin labeled NMR I), oxygenation (dynamic deoxy-myoglobin (dMb) ¹H NMR S) and mitochondrial function (spectroscopy ³¹P) at rest, during and after an ischemic exercise of calf muscles.

Results: In the diabetic patients, maximal post-ischemic perfusion was lower in the diabetic patients as compared to control subjects (C: 49.2 ± 3.3 ; $p=0.06$ versus D1: 40.4 ± 3.8 ml/min.100g; $p < 0.05$ versus D2: 41.4 ± 1.8 and versus D3: 37.5 ± 2.8 ml/min.100g). The oxygenation parameters were similar between groups. Mitochondrial oxidative activity was impaired in diabetic patients as compared with control subjects, with a more delayed half-time phosphocreatine recovery (C: 31.0 ± 1.8 vs D1: 42.1 ± 2.9 , D2: 36.2 ± 1.8 and D3: 37.5 ± 2.3 sec, $p < 0.05$).

Conclusion: Muscle perfusion is impaired in diabetic patients as compared to controls, especially in those with poor glycemic control and in those with multiple microangiopathic complications. Our results suggest that chronic hyperglycaemia, more than diabetic microangiopathy, affects mitochondrial function in skeletal muscle of type 2 diabetic patients.

Alpha-lipoic acid reduces platelet reactivity in type 1 diabetic subjects

G. Scalone, G. Scavone, F. Zaccardi, I. Battipaglia, M. Milo, R. Mollo, F. Martini, D. Pitocco, G.A. Lanza, F. Crea, G. Ghirlanda; Catholic University, Rome, Italy.

Background and aims: A higher platelet reactivity has been associated with an increased thrombotic risk. An enhanced oxidative stress is associated with an increased TxA₂ biosynthesis and administration of supplements of vitamin E reduces oxidative stress levels and platelet reactivity. Alpha lipoic acid (ALA) is an anti-inflammatory and antioxidant molecule used in diabetic neuropathy. Aim of this study was to investigate the effect of ALA on platelet function in type I diabetic patients.

Materials and methods: We consecutively enrolled 51 type 1 diabetic subjects (mean age 44.6±10.6 years, 27 males) without any overt cardiovascular disease, who were randomized to treatment with ALA 600 mg daily (n=26) or placebo (n=25) for 4 weeks. Platelet reactivity was assessed at baseline and at follow-up by measuring the aggregation time in response to adenosine-diphosphate (ADP) + collagen with the PFA-100 method, and platelet expression of receptors glycoprotein IIb/IIIa (CD41) and P-selectin (CD62), before and after ADP stimulation (10^{-7} M), by flow cytometry.

Results: There were no significant differences in the main clinical characteristics between the two groups. At baseline, PFA-100 aggregation time and CD41 and CD62P platelet expression were similar in the two groups, both before and after ADP stimulation. After 4 weeks of treatment, ALA group showed a prolonged PFA-100 aggregation time and a lower CD41 and CD62 platelet receptor expression, both before and after ADP stimulation, compared to the placebo group (Table). Oxidative stress (8-iso PGF₂) did not change significantly in both ALA- and placebo-group.

Conclusion: Overall, these results show a reduced activation and reactivity of platelets after ALA treatment in type 1 diabetic patients. Whether these favorable effects on platelet reactivity by ALA may translate into clinical benefits would deserve assessment in large randomized clinical trials.

PFA-100 aggregation time and platelet receptor expression before and after 4 weeks of ALA

Before treatment	ALA group	Placebo group	P
Aggregation time (sec)	98 (85-106)	102 (88-107)	0.092
CD41 (MFI) - Before ADP	201 (131-236)	187 (156-228)	0.038
CD41 (MFI) - After ADP	220 (141-304)	216 (191-269)	0.150

Initiation of insulin therapy ameliorates fibrinolysis in type 2 diabetes

F. Holleman¹, B.A. Lemkes¹, J.H. De Vries¹, M. Nieuwdorp¹, R. DeGroot², J.B.L. Hoekstra¹, J.C.M. Meijers³; ¹Internal Medicine, Academic Medical Centre, Amsterdam, ²sanofi-aventis, Gouda, ³Experimental Vascular Medicine, Academic Medical Centre, Amsterdam, Netherlands.

Background and aims: The prothrombotic state found in type 2 diabetes pairs hypercoagulability with impaired fibrinolysis. Both may be related to hyperglycemia-induced damage to the endothelial glycocalyx. This layer of proteoglycans and glycosaminoglycans protecting the vascular endothelium is involved in regulation of hemostasis. Our aim was to determine the effect of improved glycemic control by the initiation of insulin therapy on circulating components of the endothelial glycocalyx and markers of coagulation and fibrinolysis.

Materials and methods: In a random sample of 104 participants from the 24-week L2T3 trial in which 973 insulin-naïve patients with type 2 diabetes inadequately controlled on oral agents were randomized to insulins glargine or detemir, we measured these parameters at baseline and at the end of the study at a central laboratory. Data are expressed as medians (interquartile range) and tested non-parametrically; multivariate analysis was performed by linear regression.

Results:

Markers of coagulation and fibrinolysis	Baseline	24 Weeks	P-value
Coagulation			
Antithrombin (%)	106 (99-114)	104 (97-113)	0.059
Factor VIII (%)	71 (55-84)	65 (52-84)	0.095
Von Willebrand factor (%)	110 (84-146)	112 (83-141)	0.583
Prothrombin fragment 1+2 (pmol/l)	165 (136-218)	163 (135-194)	0.039
Coagulation/fibrinolysis			
D-dimer	0.3 (0.2-0.4)	0.3 (0.2-0.4)	0.713
Fibrinolysis			
Plasmin-antiplasmin complex (microg/l)	369 (306-466)	416 (343-515)	<0.001
Plasminogen activator inhibitor-1 (ng/ml)	100 (64-159)	87 (56-139)	0.007
Clot lysis time (min)	71 (60-85)	65 (58-77)	0.001

During the trial HbA_{1c} dropped from 8.8±0.9% to 7.2±0.9% (mean±sd) in this cohort. Markers of coagulation or glycobiology (data not shown) were not affected. However, significant changes were found in the markers of fibrinolysis. In multivariate analysis, endpoint HbA_{1c} was the most important predictor of these improvements.

Conclusion: Initiation of basal insulin therapy ameliorates the hypofibrinolytic state in type 2 diabetes, without affecting general markers of coagulation or glycobiology.

Early detection of atherosclerosis in asymptomatic patients with type 1 diabetes

E. Aguilera¹, N. Alonso¹, E. Pizarro², J. Reverter¹, I. Salinas¹, B. Soldevila¹, S. Pellitero¹, A. Lucas¹, M. Puig-Domingo¹;

¹Endocrinology and Nutrition Unit, Hospital Germans Trias i Pujol, Badalona, Barcelona, ²Endocrinology and Nutrition Unit, Hospital de Mataró, Barcelona, Spain.

Background: Type 1 diabetes mellitus (T1D) is associated with an increase in cardiovascular disease compared to the non-diabetic population, although there are few data on the prevention and screening of these patients. Different studies have demonstrated the functional and structural vascular changes produced in early stages of the evolution of T1D. Carotid artery intima-media thickness (cIMT) is a marker of atherosclerosis which is correlated with coronary disease. Multiple slice computerized tomography (CT) allows anatomical images of the coronary arteries to be non-invasively obtained by the quantification of calcification (calcium score).

Aim: Evaluate the presence of early atherosclerosis in asymptomatic T1D patients with an evolution of more than 10 years, with no history of ischemic or macrovascular heart disease.

Materials and methods: 90 T1D patients consecutively recruited from the outpatient clinic were studied (48 males; age: 37.2±7.6 years, 21.2±8.3 years of T1D evolution; BMI: 25.1±3.4 kg/m², HbA_{1c}: 7.9±1.0%; total cholesterol 182.9±23.1 mg/dl; HDL 58.8±14.2 mg/dl, LDL 106.9±21.6mg/dl; 64% non-smokers; 28% retinopathy; 11% microalbuminuria). Carotid ecography was performed to determine the mean cIMT (common carotid, bifurcation and right and left internal) and the presence of atheroma plaques. A high resolution multidetector CT with ECG was undertaken for calcium analysis and quantification.

Results: The mean cIMT was 0.57±0.13mm. 13/90 patients presented atheroma plaques and significantly higher HbA_{1c} (8.6±0.9% vs. 7.7±1.0% p=0.003) and a greater mean cIMT compared to patients without plaques (0.53±0.11mm. vs. 0.75±0.13mm p=0.001). 16/90 patients showed a calcium score > 0, a significantly higher age and HbA_{1c} (42.2±5.2 vs. 36.1±7.7 years p=0.003 and 8.5±0.9 vs. 7.7±1.0% p=0.004), a longer evolution of the disease

(26.0±9.4 vs. 20.2±7.8 years $p=0.02$) and a greater mean cIMT (0.53±0.11 mm. vs. 0.70±0.17 mm. $p=0.001$) compared to patients with score of 0.

Conclusion: A considerable percentage of our T1D patients with more than 10 years of disease evolution presented data suggestive of atherosclerosis, thus the inclusion of non-invasive screening methods for the detection of early atherosclerosis should be considered in routine clinical practice.

Increased QT time and increased creatinine level are additive risk factors for mortality in patients with diabetes mellitus and peripheral arterial disease

M. Löndahl^{1,2}, K. Fagher^{1,3},

¹Endocrinology, Clinical Sciences, Lund, ²Department of Endocrinology,

³Department of Emergency Medicine, Skane University Hospital, Lund, Sweden.

Background and aims: Long QT-time, nephropathy and peripheral arterial disease are well established risk factors for mortality in diabetic as well as non-diabetic patients. The magnitude of combination of long QT-time and increased creatinine level as risk factor for mortality in a high risk population such as diabetic patients with lower extremity arterial disease and foot ulcer is however unknown. The aim of this study was to evaluate the significance of the combination of increased QT-time and increased creatinine level on long-term mortality in patients with diabetes and arterial disease in the lower limb.

Materials and methods: A retrospective chart study was performed including all patients with a foot ulcer and critical ischemia visiting the Diabetic Foot Clinic during one year. Peripheral ischemia was defined as previous performed vascular surgery including PTA, present ankle-brachial-index less than 0.8 or systolic arterial toe blood pressure below 50 mm Hg. Patients were divided into groups according to QTc-time \leq or $>$ 440 ms and creatinine levels of \leq or $>$ 100 (men) / \leq or $>$ 80 (men). Data are given as median and 25 and 75 percentiles. Differences between groups were evaluated using Fischer's exact test and Mann-Whitney-U-test. $P<0.05$ is considered as statistical significant.

Results: 102 patients (64 M / 38 F, 22 with type 1 diabetes / 80 with type 2 diabetes) with an age of 70 (34–80) years and a diabetes duration of 12 (0–48) years were included. Of these 8 patients with on-going dialysis were excluded. Hypertension was seen in 82 patients, heart failure in 38 and a history of myocardial infarction was present in 33 patients. At baseline HbA_{1c} was 60 mmol/l (52–71) and creatinine was 87 (71–113) μ mol/l (ref 50–100), ABI was 0.70 (0.49–0.80) and TBP was 35 (10–45) mm Hg. Group 1 consisted of patients with normal QTc interval (QTc-) and normal creatinine (crea-), group 2 of patients with normal QTc interval but high creatinine (crea+), group 3 of patients with prolonged QTc interval (QTc+) but normal creatinine and group 4 of patients with prolonged QTc interval and high creatinine level. The 8-year mortality rate was significantly higher in patients with the combination of prolonged QTc interval and pathological creatinine level ($p<0.0032$, figure 1).

Conclusion: The combination of prolonged QTc interval and pathological creatinine level is associated with increased short- and long term mortality in diabetic patients with peripheral arterial disease.

IScore mortality prediction early after hospitalisation of an acute ischaemic stroke in diabetic patients: is this a validated and accurate prediction?

I. Protopsaltis¹, V. Dragoumanos¹, N. Melas², M. Vourvou³, E. Fouteris¹, A. Melidonis^{1,2},

¹Diabetes Center, Tzanio General Hospital, Piraeus, ²1st Internal Medicine Clinic, Tzanio General Hospital, Piraeus, ³Intensive Care Unit, Papageorgiou General Hospital, Thessaloniki, Greece.

Background and aims: Several prognostic models have been developed for evaluation of neurologic status, severity, and short-term functional outcome of stroke patients. IScore is a novel tool which has been recently developed by Canadian researchers in order to identify mortality rates within 30 days and 12 months after an ischemic stroke (IS). Since diabetic patients constitute a high risk group for IS, early prognosis is particularly important, as timely and appropriate therapeutic intervention will result in better post discharge quality care and a more judicious health decision system. The aim of the present study was to evaluate IScore mortality prediction rates in diabetic IS patients.

Materials and methods: This retrospective study was conducted in a tertiary Greek hospital. Two-hundred and sixty six ($n=266$) consecutive IS type I or type II diabetic patients, comprised the study population. Thirty day and 12 month scores were individually calculated for each patient and actual mortality was monitored at the same time intervals. IScore's predictors of mortality included older age, male sex, severe stroke, non-lacunar stroke subtype, glucose ≥ 7.5 mmol/L (135 mg/dL), history of atrial fibrillation, CAD, CHF, cancer, dementia, kidney disease on dialysis and dependency prior to the stroke. Logistic regression analysis was conducted in order to identify how accurate IScore measurements predict actual mortality. ROC curves evaluated sensitivity and specificity of IScore mortality rates.

Results: Thirty one (11.7%) out of 266 patients died 30 days after the IS. In total 41 (15.4%) patients died after 12 months. Mean (\pm SD) values for the 30 day and 12 month IScore was 176.4 \pm 42.1 and 142.6 \pm 31.5 respectively. Thirty day (HR=1.07, 95% CI: 1.04–1.09, $p<0.001$) and 12 month scores (HR=1.12, 95% CI: 1.08–1.16, $p<0.001$) were significant predictors of mortality in diabetic IS patients. A ROC curve estimated that a score of 208 (AUC=0.941, 95% CI: 0.91–0.96, $p<0.001$) has 100% (95% CI: 88.8–100) sensitivity and 83.8% (95% CI: 78.5–88.3) specificity for 30 day mortality, while a score of 169 (AUC=0.964, 95% CI: 0.93–0.99, $p<0.001$) reflects 92.6% (95% CI: 80.1–98.5) sensitivity and 92% (95% CI: 87.7–95.2) specificity for 12 month mortality. Compared to previous study in diverse population, these results exhibit higher sensitivity and specificity indicating that IScore can predict mortality more precise in diabetic patients.

Conclusion: IScore represents a well validated and accurate tool in identifying mortality early after hospitalization in acute IS diabetic patients. The identical acute clinical parameters and chronic co-morbid conditions identified within hours of admission can be used in order to predict mortality in a high-risk population after an acute stroke. In addition, IScore exhibits higher predictive accuracy specifically for diabetic patients regarding the 30 day and 12 month mortality rates.

Screening strategy for asymptomatic coronary heart disease in Japanese subjects with type 2 diabetes

Y. Kawasaki, Y. Hamamoto, S. Honjo, K. Mori, H. Ikeda, Y. Wada, H. Koshiyama;

Center for Diabetes and Endocrinology, Kitano Hospital, Osaka, Japan.

Background and aims: There has been no consensus about the screening methods for asymptomatic coronary heart disease (CHD) in patients with diabetes. We investigated the rationale of screening methods using the treadmill tolerance test (TTT) as the first line test or the risk-guided approach including the 1998 ADA guideline for the detection of asymptomatic coronary heart disease (CHD) in Japanese patients with type 2 diabetes.

Materials and methods: Subjects included consecutive inpatients with type 2 diabetes ($n=481$). They were checked with electrocardiogram (ECG) at rest and TTT, and those with abnormal TTT findings were investigated with stress myocardial perfusion scintigraphy (MPS), and those with abnormal MPS findings were examined with coronary angiography (CAG). The number of patients who met the criteria of ADA guideline or those of patients with cardiac autonomic neuropathy (CAN) was examined. CAN was defined as the coefficients of variation of R-R intervals of ECG less than 2%.

Results: Among all subjects ($n=481$), 150 patients (31.2%) could not perform the TTT well enough for the test to be conclusive. Among the subjects who were able to complete TTT ($n=331$), a total of 69 had positive TTT, among whom, a total of 22 had positive MPS. A total of 14 subjects received CAG, and eight of them (only 1.7% of the total subject) were finally indicated to have CHD. The patients who met the criteria of ADA were 71.0% of TTT-positive patients, 68.2% of MPS-positive patients, and 75.0% of CAG-positive patients, respectively. The patients with CAN were 42.0%, 50.0% and 50.0% of patients with positive TTT, MPS and CAG, respectively. The unexpectedly low rate of asymptomatic CHD in our screening suggested that considerable subjects with asymptomatic CHD had escaped the present screening method; in fact, among those with negative results, three patients developed CHD during the follow-up. Furthermore, it was suggested that the risk-guided approach with the ADA guideline or that incorporating CAN with risk factors would have overlooked some subjects with CHD, even those who could be detected in the present screening.

Conclusion: These results suggest that neither the screening methods using TTT as the first line test nor the risk-guided approach including the ADA guideline are sufficiently adequate for detecting asymptomatic CHD in Japanese subjects with type 2 diabetes.

Cardiovascular risk prediction is improved by adding asymptomatic coronary status to routine risk assessment in type 2 diabetic patients

P. Valensi, M. Nguyen, B. Chanu, I. Banu, S. Chiheb, K. Takbou, E. Cosson; Department of Endocrinology, Diabetology, Nutrition, Paris Nord University, France.

Background and aims: The aim of the study was to evaluate if silent myocardial ischemia (SMI) and silent coronary artery disease (CAD) provide significant additional value to routine cardiovascular risk assessment in type 2 diabetic (T2D) patients.

Materials and methods: We followed up to a first cardiovascular event (cardiac death, acute coronary syndrome, congestive heart failure, secondary coronary revascularization procedure, stroke, peripheral revascularization procedure and lower leg amputation) 688 (322 men, 59 ± 8 years) consecutive asymptomatic T2D patients with ≥ 1 additional risk factor who had been prospectively screened between 1992 and 2006 for SMI by stress myocardial scintigraphy and for silent CAD by coronary angiography.

Results: SMI was found in 207 (30.1%) patients and CAD in 76 of those with SMI. Ninety-eight patients had a first cardiovascular event during a 5.4 ± 3.5 [range: 0.1–19.2] year follow-up period. Cox regression analysis considering parameters predicting events but not SMI and CAD (“routine assessment”) showed in univariate analyses that macroproteinuria (hazard ratio 3.33 [1.74–6.35], $p < 0.001$), current more intensive multifactorial care (HR 0.27 [0.15–0.47], $p < 0.001$) and peripheral/carotid occlusive arterial disease (PCOAD: HR 4.33 [2.15–8.71], $p < 0.001$) independently predicted cardiovascular events. When added into the model, SMI (HR 1.76 [1.00–3.12], $p = 0.05$) and CAD (HR 2.28 [1.24–4.57], $p < 0.01$) were also independently associated with events. The cumulative probability of cardiovascular events increased with routine risk assessment (macroproteinuria and/or no current multifactorial care and/or PCOAD) and SMI: routine-/SMI- hazard ratio 1; routine+/SMI- HR 1.4 [0.6–3.5]; routine-/SMI+ HR 6.2 [3.3–11.7] and routine+/SMI+ HR 12.1 [6.4–22.5]. SMI also added to the prediction of an event in the following 5 years above and beyond routine assessment risk prediction (c statistic with or without SMI 0.788 [0.720–0.855] and 0.705 [0.616–0.794]; Hosmer-Lemeshow χ^2 5.13, $p = 0.643$ and 1.34, $p = 0.932$, respectively).

Conclusion: SMI and silent CAD are predictive of cardiovascular events in T2D patients additionally to routine risk predictors, especially represented by PCOAD, macroproteinuria and non intensive management as usually provided before 2000.

1257

Cardiovascular disease and risk factor profiles of patients with type 2 diabetes mellitus who were eligible for but did not receive a statin

K. Tunceli¹, P. Sun², Q. Zhang¹, B. Ambegaonkar¹, K. Lento¹, M.J. Davies¹, T. Seck¹, L. Radican¹;

¹Merck Sharp & Dohme Corp., Whitehouse Station, USA, ²Kailo Research Group, Indianapolis, USA.

Background and aims: Statin therapy is recommended for nearly all patients with type 2 diabetes mellitus (T2DM) to reduce the risk of major cardiovascular (CV) events. Despite these recommendations, studies have shown that up to 60% of eligible patients with T2DM are untreated with statins. Therefore, it was of interest to characterize the risk factor profile of a cohort of patients with T2DM who were not on statins for 2 years despite being eligible for statin treatment.

Materials and methods: Using the General Electric electronic medical record database, patients with T2DM were included if they were ≥ 18 years of age at diagnosis and not on a statin during the baseline period (2007) and 2-year follow-up period (2008–2009). Statin eligibility was assessed using the American Diabetes Association (ADA) 2008 recommendations. CV disease (CVD) and risk factor profiles were determined by searching the database for diagnoses of specific CV-related events. Additional CV risk factor determinations were made using lipid and blood pressure (BP) measurements, obesity and smoking status, gender, and age.

Results: In a cohort of 87,351 patients eligible but untreated with statins (46% male), mean age at baseline was 60 years (92% > 40 years old) and mean HbA_{1c} was 7.1%, with 46% on antihyperglycaemic therapy. For pre-existing comorbidities and CV risk factors recorded during the 1-year baseline period, 1% of patients had overt CVD, 8% had dyslipidaemia, 76% had hypertension, 2% were smokers, and 52% were obese. For specific clinical measures at baseline, 28% had an LDL-C ≥ 100 mg/dL (2.6 mmol/L), 36% had an HDL-C below gender-specific targets, 72% had a systolic BP ≥ 140 mmHg, and 46% had diastolic BP ≥ 90 mmHg. During the 2-year follow up period without statin use, an additional 7% of patients had a new diagnosis for overt CVD, 9% for dyslipidaemia, 9% for hypertension, and 11% for obesity; and 2% started smoking.

Conclusion: Patients with T2DM eligible for, but not on statins, often have CVD and/or risk factor profiles that are suggestive of a need for CV risk reduction. Thus, a treatment gap exists between actual and optimal treatment patterns in statin-eligible patients with T2DM.

Effects of pravastatin on coronary events and cerebral infarction in hypercholesterolaemic Japanese men with and without diabetes mellitus

J. Sasaki¹, K. Shimomura¹, K. Fukuyo¹, Y. Ikeda², S. Biro³;

¹Pharmaceutical Medicine, Internationaional University of Health and, Fukuoka,

²Internal Medicine, Tagawa Municipal Hospital, ³Internal Medicine, Tsukasa

Health Care Hospital, Kagoshima, Japan.

Background and aims: Since, the effect of statin was still uncertain for Japanese, whose coronary artery disease morbidity and mortality are lower than western countries, we examined the effects of pravastatin for coronary events and cerebral infarction in Japanese.

Materials and methods: The Kyushu Lipid intervention Study (KLIS) recruited 4185 men aged 45–74 years with serum total cholesterol of 220 mg/dl or greater to undertake either pravastatin or conventional treatment (including hypolipidemic drugs other than statin, probucol fibrate) and follow up for 5 years. The Cox proportional hazards model was used to calculate relative risk.

Results: At baseline, 27% of patients had a diabetes mellitus. There were 118 coronary events (acute myocardial infarction, coronary angioplasty, cardiac death) and 89 cerebral infarction in a 5-year follow-up period. Pravastatin treatment (10mg/day) was associated with 45% lower risk of coronary events in diabetes mellitus while 7% increase risk without diabetes mellitus. Pravastatin treatment was associated with 28%, 44% lower risk of cerebral infarction with and without diabetes mellitus respectively.

Conclusion: Low dose pravastatin was effective at decreasing coronary events and cerebral infarction in Japanese hypercholesterolemic men with diabetes mellitus.

The role of methylglyoxal in diabetic and normal cardiac ischaemia

J. Crisóstomo¹, P. Matafome^{1,2}, D. Santos-Silva¹, L. Rodrigues¹, C.M. Sena¹, P. Pereira², R.M. Seica¹;

¹Institute of Physiology, IBILI, ²Center of Ophthalmology, IBILI, Faculty of Medicine, Coimbra, Portugal.

Background and aims: Patients with type 2 diabetes have an increased risk to develop cardiac ischemia and their response to such accidents is impaired. In the worst case, cardiac ischemia can lead to myocardial infarction, causing death to nearly 75% of diabetic population. The high concentration of glucose in diabetic cells results in increasing concentration of a secondary metabolite, the methylglyoxal (MG) that is known to have deleterious effects. We believe that prolonged exposure to MG can induce, in normal subjects, changes similar to those that occur in diabetes. Therefore, we aimed to understand the role of MG on cardiac ischemia in diabetic and normal animal model.

Materials and methods: We performed a comparative study between three groups: normal rats (W), type 2 diabetic non-obese Goto-Kakizaki rats (GK) and normal rats submitted to chronic administration of MG (WMG). Animals were sacrificed with 6 months of age, and their hearts were perfused in a Langerdorff system. At this point, hearts were submitted to different experimental conditions: control (c); ischemia (i) and ischemia-reperfusion (ir). Glycemic profile and several parameters in cardiac tissue were evaluated using mostly western blot technique.

Results: MG administration did not change glycemic profile in control animals. Comparing to W, plasmatic MG levels were higher in GK ($p<0.05$) and WMG ($p<0.05$); the cardiac MG levels were significantly higher in WMG ($p<0.001$). Looking to cardiac tissue staining of AGEs (Advanced Glycation End Products) and their receptors (RAGEs), it was observed an increasing fluorescence in GK and WMG groups. JNK protein expression particularly demonstrated a decreasing in (i)-subgroups among the three groups ($W>GK>WMG$); levels in WMG(ir) rats were also decreased ($p<0.001$) in comparison to W(ir). Phospho-JNK expression increased only in W(i) and GK(i) ($p<0.001$; $p<0.05$), comparing to their controls. All (ir)-subgroups showed P-JNK expression lower than their respective (c)-subgroups ($p<0.05$). Regarding to Akt protein, it levels decreased generally in (i)- and (ir)-subgroups among three groups. Levels of GK and WMG (c)-subgroups decreased in relation to W ($p<0.001$); the (i)-subgroups levels also decreased among the three groups ($p<0.01$; $p<0.05$), and (ir)-subgroup levels were only significantly lower in WMG ($p<0.05$). In phosphorylated form of Akt, it was observed decreasing levels in GK and WMG, when compared to W group: control ($p<0.001$; $p<0.01$); ischemic ($p<0.01$) and ischemic-reperfusion ($p<0.05$; $p<0.01$) subgroups. The ratio Bcl-2/Bax showed noteworthy an increase in W(i) and GK(i) comparing to their controls ($p<0.01$; $p<0.05$). WMG(i) showed a less increased ratio that was significantly lower than W(i) and GK(i) with $p<0.01$. Relating to W(c), GK and WMC (c)-subgroups decreased their values ($p<0.05$). Levels of Caspase 3 increased significantly in W(ir) and GK(ir) ($p<0.05$), comparing respectively with W(c) and GK(c). GK(ir) and WMG(ir) levels were higher than W(ir) ($p<0.05$).

Conclusion: The administration of methylglyoxal in normal rats is able to mimic the profile founded in diabetic rats and even some parameters are more impaired. Our results re-affirm the toxicity of the compound and demonstrate the potentiality of methylglyoxal to be a therapeutic target in diabetic cardiac ischemia disease.

Vascular actions of methylglyoxal with implications for endothelial dysfunction

C.M. Sena¹, P. Matafome¹, J. Crisóstomo¹, L. Rodrigues¹, C. Bento², P. Pereira², R.M. Seica¹;

¹Institute of Physiology, ²Center of Ophthalmology, IBILI, Faculty of Medicine, University of Coimbra, Portugal.

Background and aims: Modern diets can cause modern diseases. Research has linked a metabolite of sugar, methylglyoxal (MG), to the development of diabetic complications, but the exact mechanism has not been fully elucidated.

The present study was designed to investigate whether MG could directly influence endothelial function, oxidative stress and inflammation in Wistar and Goto-kakizaki (GK) rats, an animal model of type 2 diabetes.

Materials and methods: Wistar and GK rats treated with MG in the drinking water for 3 months were compared with the respectively control rats. The effects of MG were investigated on NO-dependent vasorelaxation in isolated rat aortic arteries from the different groups. Insulin resistance, NO bioavailability, glycation, a pro-inflammatory biomarker monocyte chemoattractant protein-1 (MCP-1) and vascular oxidative stress were also evaluated.

Results: Methylglyoxal treated Wistar rats significantly reduced the efficacy of NO-dependent vasorelaxation ($p<0.001$). This impairment was accompanied by a threefold increase in the oxidative stress marker nitrotyrosine. Advanced glycation endproducts (AGEs) formation was significantly increased as well as MCP-1 and the expression of the receptor for AGEs (RAGE). NO bioavailability was significantly attenuated and accompanied by an increase in superoxide anion immunofluorescence. Methylglyoxal treated GK rats significantly aggravated endothelial dysfunction, oxidative stress, AGEs accumulation and diminished NO bioavailability when compared with control GK rats.

Conclusion: These results indicate that methylglyoxal induced endothelial dysfunction in normal Wistar rats and aggravated the endothelial dysfunction present in GK rats. The mechanism is at least in part by increasing oxidative stress and/or AGEs formation with a concomitant increment of inflammation and a decrement in NO bioavailability. The present study provides further evidence for methylglyoxal as one of the causative factors in the pathogenesis of atherosclerosis and development of macrovascular diabetic complication.

Advanced glycation end-products-induced vascular calcification is mediated by oxidative stress: functional roles of NAD(P)H-oxidase

Y. Tada¹, S. Yano², K. Okazaki², N. Ogawa², M. Morita², M. Yamamoto², T. Yamaguchi², T. Sugimoto²;

¹Matsue City hospital, ²Department of Internal Medicine 1, Shimane University Faculty of Medicine, Izumo, Japan.

Background and aims: Vascular calcification is associated with increased morbidity and mortality in patients with diabetes mellitus and end-stage kidney disease. Especially, medial artery calcification, known as Monckeberg's type of calcification, is often detected in these patients. Growing evidence suggests that advanced glycation end-products (AGEs) are associated with vascular calcification, although their actions are still unclear. On the other hand, oxidative stress leads to vascular damage through diverse mechanisms. Thus, we investigated an *in vitro* study to elucidate the effects of AGEs and the roles of NAD(P)H oxidase in the pathogenesis of vascular calcification.

Materials and methods: Rat vascular smooth muscle cells (A7r5) were incubated in calcification medium with AGE3 to measure calcium deposition, to evaluate apoptosis (ELISA) and to determine mRNA expression levels of osteopontin (OPN), osteocalcin (OC), Runx2, Nox-1, Nox-4, and p22phox (real-time PCR). AGE3 was prepared by incubating albumin with 0.1M glycolaldehyde and 5mM diethylenetriaminepentaacetic acid in 0.2M phosphate buffer (pH7.4) at 37°C for 7 days. Nox-1, Nox-4, and p22phox mRNAs were knocked down by using small interfering RNA (siRNA) technique.

Results: Calcium deposition was increased by AGE3 in a dose- (100-300µg/dl) and time- (3-7days) dependent manner in A7r5 cells. AGE3 was the most potent in calcium deposition among AGEs, which we had examined. Expression levels of the OPN, OC, and Runx2 mRNAs were significantly higher in AGE3 treatment than those in control BSA treatment, indicating the osteoblastic transdifferentiation of the vascular smooth muscle cells. In addition, apoptosis was enhanced within 24hrs in cells treated with AGE3, compared to that with control BSA. Increased expressions of Nox-1, Nox-4, and p22phox mRNAs (3 to 6 folds) were also observed in cells treated with AGE3, suggesting that AGEs most probably promote reactive oxidative species production resulting in the progression of calcium deposition. Therefore, we examined the effects of silencing of these mRNAs by using siRNA transfection method. We found that AGE3-stimulated calcium deposition was significantly decreased in the cells transfected by either Nox-4 or p22phox siRNA, which effectively depressed their mRNA levels, compared to the controls (scramble). In contrast, no significant effect was shown in silencing of Nox-1, although its mRNA level was effectively depressed to less than 5%.

Conclusion: The present findings indicate the involvement of osteoblastic transdifferentiation of the vascular smooth muscle cells and these apoptosis as well as oxidative stress in the pathogenesis of AGEs-induced vascular calci-

fication. Our findings also suggest that activated NAD(P)H oxidase, which is induced by increased expression of Nox-4 and p22phox, may play important roles. These molecules could be a target of new strategy to prevent vascular calcification as well as vascular damage.

1262

Endothelial progenitor cells and glycated albumin level are correlated with atherogenesis in type 2 diabetic patients

H. Seok¹, B.-W. Lee¹, J. Moon¹, H. Kim¹, M. Chae², Y. Kim³, B. Cha¹, H. Lee¹;

¹Department of Internal Medicine, ²Brain Korea 21 project for Medical Science, ³Department of Radiology, Yonsei University College of Medicine, Seoul, Republic of Korea.

Background and aims: We investigated the relationship between endothelial progenitor cells (EPCs) and atherosclerotic plaque formation in type 2 diabetic patients without documented ischemic disease.

Materials and methods: We conducted a clinic-based, prospective study of type 2 diabetic patients. A total of 73 subjects (38 men and 35 women; mean age, 56.2 ± 7.7 years) were enrolled after cardiac MRI and ankle-brachial index assessments to exclude patients with ischemic disease. Intima media thickness and plaques in the carotid artery were measured by ultrasonography. Numbers of circulating EPCs (CD34⁺/CD133⁺/CD309⁺ cells) were enumerated by flow cytometry.

Results: Compared to subjects without carotid artery plaques, patients with plaques were significantly older (52.3 ± 8.0 vs. 57.8 ± 7.1 years, $p = 0.006$) and had decreased EPC levels (412 (349) vs. 279 (354), $p = 0.027$). Serum glycated albumin (GA) level and GA/HbA1c ratio tended to be lower in patients with plaques ($p = 0.091$ and 0.067 , respectively). Binary logistic regression analysis revealed that old age, a low EPC level, and a high serum GA level were independently correlated with carotid artery plaque formation. Most subjects with a lower EPC count and a higher GA/HbA1c ratio than the medians of the respective parameters had carotid artery plaques (Fig.1).

Conclusion: EPCs and serum GA level could be sensitive biomarkers indicating endothelial protection and damage for predicting atherogenesis in type 2 diabetic patients.

Figure 1. Scatter plot showing the distribution of subjects with and without carotid artery plaque formation according to serum GA/HbA1c and EPC levels. Carotid artery plaque formation was assessed by ultrasonography. GA = glycated albumin; EPC = endothelial progenitor cells; The symbol "●" indicates the medians of the respective parameters; The symbol "○" indicates the patients with carotid plaques; The symbol "×" indicates the patients without carotid plaques.

Increased plasma levels of the methylglyoxal-derived advanced glycation end-product tetrahydropyrimidine in type 1 diabetes and in atherosclerotic plaques: association with soluble vascular cell adhesion molecule 1

M.G.A. van Eupen¹, M.T. Schram¹, H.M. Colhoun², H.W.M. Niessen³, C.D.A. Stehouwer¹, C.G. Schalkwijk¹;

¹Department of Internal Medicine, Maastricht University Medical Centre (MUMC), Netherlands, ²Biomedical Research Institute, University of Dundee, UK, ³Department of Pathology, VU Medical Centre, Amsterdam, Netherlands.

Background and aims: Methylglyoxal (MGO) is a major precursor in the formation of Advanced Glycation Endproducts (AGEs). MGO primarily reacts with arginine to three MGO-derived AGEs: 5-hydro-5-methylimidazolone, argpyrimidine and tetrahydropyrimidine (THP). MGO-derived AGEs are implicated in the development of vascular complications. We studied, with the use of a novel antibody, whether THP is elevated in type 1 diabetes mellitus (T1DM) and related to endothelial dysfunction, low-grade inflammation and atherosclerosis.

Materials and methods: We raised and characterized a monoclonal antibody against the MGO-derived AGE THP and developed a competitive ELISA. THP was measured in 196 T1DM subjects and 195 controls. We measured plasma markers of endothelial activation, i.e. soluble vascular cell adhesion molecule 1 (sVCAM-1) and Von Willebrand factor (vWF), and low-grade inflammation, i.e. high-sensitivity C-Reactive Protein (hsCRP). In addition, we performed immunohistochemical analyses to determine the presence of MGO-derived THP and the major AGE N^ε-(Carboxymethyl)lysine (CML) in atherosclerotic arteries.

Results: The raised antibody was specific for the MGO-derived AGE THP. Plasma levels of THP were higher in subjects with T1DM than in control subjects with median and IQR of 115.5 U/ μ l [102.4 - 133.2] and 109.8 U/ μ l [91.8 - 122.3], respectively ($p=0.03$). In regression analyses sVCAM-1 was significantly associated with plasma THP, independent of possible confounders. Per SD increase in THP, sVCAM-1 increased by 0.47 SD ($p<0.001$). THP was not associated with vWF, nor with hsCRP. We found no association of THP with microvascular complications. THP, as well as CML, was detected in atherosclerotic arteries in extracellular lipids, macrophages and calcification sites, including surrounding smooth muscle cells. CML was also present in the endothelium and adventitial blood vessels, while THP was not.

Conclusion: Plasma levels of the MGO-derived THP are significantly associated with diabetes and correlated with sVCAM-1; i.e. an endothelial marker associated with atherosclerosis development. THP and CML were found in atherosclerotic arteries. Our results are consistent with a proposed pathophysiological role of the MGO-derived AGE THP in vascular complications in patients with and without diabetes.

Advanced glycation endproducts in atherosclerotic plaques: no further increase in patients with diabetes

N.M.J. Hanssen¹, C.D.A. Stehouwer¹, M.S. Huijberts¹, M. Brownlee², D.P. de Kleijn³, G. Pasterkamp⁴, C.G. Schalkwijk¹;

¹Internal medicine, Maastricht University, Netherlands, ²Albert Einstein Diabetes Research Center, Albert Einstein College of Medicine, New York, USA, ³Experimental cardiology, University Medical Center Utrecht, Netherlands, ⁴Experimental cardiology, University Medical Center Utrecht, Maastricht, Netherlands.

Background and aims: Atherosclerosis is the major underlying cause of morbidity and mortality in patients with diabetes. Advanced glycation endproducts (AGEs) are formed when concentrations of reducing sugars and reactive oxygen species increase. AGEs lead to vascular damage through alteration of protein function and interaction with their receptors. Therefore, AGEs may explain the increased risk of atherosclerotic events in diabetes. The aim of this study was to determine whether concentrations of AGEs in atherosclerotic plaques are higher in patients with diabetes.

Materials and methods: 75 plaque homogenates were randomly selected from the Athero-Express cohort, containing patients undergoing carotid endarterectomy (48% diabetes, 72% male, mean age: 67.7 ± 8.8 years). Presence of diabetes was determined on the basis of a questionnaire. The concentrations of the protein-bound AGEs N^ε-(carboxymethyl)lysine (CML),

N^ε-(carboxyethyl)lysine (CEL) and 5-hydro-5-methylimidazolone (MG-H1) in homogenates were quantified by UPLC tandem mass spectrometry. Plaque concentrations of inflammatory molecules interleukin-8 (IL-8) and monocyte chemoattractant protein-1 (MCP-1) were measured using a multiplex suspension array system. Plaques were histologically scored for lipid content. In a subset of 40 plaques, immunohistochemistry was performed with antibodies against CML and MG-H1. Data were presented as median and interquartile range and analyzed using ANOVA, after log-normalization. Correlations were calculated using the spearman method.

Results: Concentrations of AGEs in homogenates of carotid plaques of individuals without- and with diabetes did not differ significantly: CML 79.0 (58.6–126.3) vs. 90.6 (65.6–150.1) nmol/mmol lysine, $p=0.23$, CEL 89.2 (82.0–106.9) vs. 93.4 (75.7–109.0) nmol/mmol lysine, $p=0.97$ and MG-H1 367.0 (307.0–866.7) versus 406.2 (288.2–660.0) nmol/mmol lysine, $p=0.95$. Levels of MG-H1 were higher in plaques with increased fatness; no fat: 323.7 (272.9–511.4), <40% fat: 372.1 (307.4–640.9), >40% fat 445.3 (302.1–957.1) nmol/mmol lysine, $p_{\text{trend}}=0.04$. A similar, but non-significant, trend was also observed for CML, but not for CEL. Within plaques, extensive positive staining for MG-H1 and CML was present in macrophages and endothelial cells. Additionally, a correlation between MG-H1 with IL-8 ($r=0.334$, $p<0.01$) and MCP-1 ($r=0.256$, $p=0.03$) was found. This was also true for CML ($r=0.346$, $p<0.01$ and $r=0.249$, $p=0.03$, respectively). CEL was correlated with MCP-1 ($r=0.291$, $p=0.01$), but not IL-8 (0.135 , $p=0.265$).

Conclusion: The concentrations of CML, CEL and MG-H1 in atherosclerotic plaques are not further increased in patients with diabetes, suggesting that AGE formation in plaques is associated with localized plaque metabolism and inflammation, rather than with a generalized increase in metabolism due to diabetes.

Glycated albumin to glycated haemoglobin ratio (GA/HbA_{1c}) is associated with the presence of carotid plaque in patients with type 2 diabetes mellitus

A. Asai, Y. Sato, Y. Nakajima, M. Takaya, N. Takeichi, S. Takemitsu, M. Sudo, M. Nagao, T. Kano, A. Ishizaki, T. Harada, K. Tanimura, F. Okajima, H. Sugihara, S. Oikawa;
Endocrinology and Metabolism, Nippon Medical School Hospital, Tokyo, Japan.

Background and aims: Epidemiological evidence indicates that postprandial hyperglycemia is a risk factor for cardiovascular disease. Because of the shorter half-life of serum albumin compared to erythrocytes, serum glycated albumin (GA) level reflects shorter-term glycemic control status compared to HbA_{1c}. Several reports also indicated that serum GA reflects postprandial blood glucose excursions better than HbA_{1c}. Although GA (%) to HbA_{1c} (%) ratio (GA/HbA_{1c}) is generally estimated approximately 3, there is a certain range (typically 2–4) in the distribution of GA/HbA_{1c} value in patients with type 2 diabetes mellitus (T2DM). In this study, we assessed the relationship of GA/HbA_{1c} with other conventional glycemic control parameters and evaluated the potential clinical usefulness of the measurement of GA/HbA_{1c} for predicting atherosclerotic cardiovascular outcomes in T2DM.

Materials and methods: Of the patients with T2DM admitted to our hospital for glycemic control during 2005–2009, 148 patients (99 males and 49 females; 56±13 years old) were examined in this study. Exclusion criteria included endocrine complications, steroid treatment, ketosis, malignant disease, anemia, and other systemic diseases. Clinical measurements including fasting plasma glucose (FPG), GA, HbA_{1c}, and lipid profiles were taken on admission. HbA_{1c} value in Japan Diabetes Society unit (%) was used for statistical analysis. Carotid Intima-media thickness (IMT) and the presence of carotid plaque were assessed by B-mode ultrasonography performed bilaterally on common carotid artery, carotid bifurcation, and internal carotid artery. The presence of carotid plaque was defined as focal IMT ≥1.0 mm with marked protuberance. **Results:** GA/HbA_{1c} was positively correlated with age ($P<0.0001$), duration of T2DM ($P=0.0008$), FPG ($P<0.0001$), GA ($P<0.0001$), and HbA_{1c} ($P=0.0043$). Carotid plaque was presented in 85 patients, whereas 63 patients were without carotid plaque. In patients with carotid plaque, GA and GA/HbA_{1c} were higher than those without carotid plaque (GA, $P=0.015$; GA/HbA_{1c}, $P=0.0003$). On the other hand, neither FPG nor HbA_{1c} was significantly different in both groups (FPG, $P=0.49$; HbA_{1c}, $P=0.76$). The results of logistic regression analysis showed that GA/HbA_{1c} was significantly associated with the presence of carotid plaque (age- and sex-adjusted OR, 2.55; 95% CI, 1.11–6.42; $P=0.035$).

Conclusion: The positive correlation of GA/HbA_{1c} with other glycemic control parameters suggested that higher GA/HbA_{1c} value reflects worse blood glucose control. GA/HbA_{1c} value was higher in the patients with carotid plaque and was emerged as a strong predictor of the presence of carotid plaque in multivariable logistic regression analysis. Thus, the measurement of GA/HbA_{1c} may be useful to predict the risk of atherosclerotic cardiovascular events in T2DM.

1266

Soluble RAGE plasma levels are inversely associated to severity of coronary atherosclerosis and are genetically influenced

G. Basta¹, T. Navarra¹, F. Bigazzi², R. Petz¹, M.G. Andreassi¹, C. Carpeggiani¹, A. Gastaldelli¹;

¹Institute of Clinical Physiology CNR, ²Fondazione G Monasterio, Pisa, Italy.

Background and aims: Hyperglycemia is associated with increased production of AGEs (advanced glycation end-products). RAGE [receptor for AGEs] plays an important role in the development and progression of vascular disease while circulating soluble RAGE (sRAGE), acting as decoy for RAGE ligands has a protective function against vascular complications. Additionally, genetic variants of the RAGE gene have been associated with individual differences in sRAGE concentration and vascular disease risk. The aim was to examine the association between sRAGE and a functional single-nucleotide polymorphism (SNP) in the RAGE gene (Gly82Ser; rs2070600), a SNP associated with increased ligand affinity of RAGE, with severity of coronary artery disease (CAD) in patients with stable angina.

Materials and methods: A total of 277 patients (175 males, 102 with T2DM, 65.2±10.1 years) with stable angina were studied. Serum sRAGE was measured by ELISA and the Gly82Ser polymorphism (determined in a subgroup of 127 patients) was determined with a method that combined polymerase chain reaction and sequence-specific oligonucleotide probes with array technology.

Results: Patients with diseased vessels ≥2 (n=95) had significantly lower levels of sRAGE than patients with diseased vessels ≤1 (n=182) [272 (178–456) pg/mL median (interquartile range) and 518 (228–968) pg/mL respectively, $P<0.0001$] independently of T2DM. In multivariable logistic regression analysis after adjustment for potential confounders, the sRAGE levels were significantly and independently associated with severity of CAD (OR = 0.672, 95% CI=0.474–0.951, $P=0.025$). Genetic analysis revealed 4.2 % of patients with GS genotype and 95.8 % of patients with GG genotype. The RAGE GS genotype distribution did not differ between patients with diseased vessels ≤1 (5%) and those with diseased vessels ≥2 (3%) while showed an association with sRAGE levels. Specifically, subjects with GS genotype had lower sRAGE levels versus those with the common GG genotype of RAGE [184 (62–234) pg/mL and 300 (181–427) pg/mL respectively, $P=0.0021$]. RAGE Gly82Ser polymorphism ($\beta = -0.253$, $P=.0026$) and creatinine ($\beta = 0.231$, $P=.0099$) were major factors affecting sRAGE concentrations.

Conclusion: Circulating sRAGE levels are inversely associated to severity of CAD and the lowest sRAGE levels are genetically influenced. However RAGE Gly82Ser polymorphism does not seem to be involved in genetic susceptibility to CAD severity.

Lack of association between skin autofluorescence level and intermediate markers of cardiovascular risk in patients with type 2 diabetes and metabolic syndrome

C. Cugnet Anceau¹, M. Durand¹, A. Serusclat², P. Chiroulet², A. Crand¹, M. Moret¹, L. Groisne¹, P. Moulin¹;

¹U11 Fédération d'Endocrinologie, ²Service de Radiologie, Bron, France.

Background and aims: The AGE Reader is supposed to provide a non invasive determination of the accumulation of advanced glycation end products (AGE) in the skin. Consequently this measurement should be related to microvascular and cardiovascular complications more especially as AGE level was previously reported associated with ischemic cardiovascular mortality in type 2 diabetes. Consequently we hypothesized that skin autofluorescence might be related to carotid intima-media thickness (IMTc) and pulse wave velocity (PWV).

Materials and methods: We studied 22 type 2 diabetic patients, 62±8 years old (group A), 25 type 1 diabetic patients 50±9 (group B), 20 patients with

metabolic syndrome, 55 ± 10 (group C), and 43 control subjects, 49 ± 8 (group D). Age, body mass index, blood pressure, duration of diabetes, microvascular and cardiovascular complications were recorded. HbA1C level. PWV (by pulse pen), IMTc and AGE levels (AGE Reader) were measured for each patient.

Results: AGE levels were mildly correlated with age ($r^2=0.15$, $p<0.001$). A mild increase in AGE level was observed only in group A (2.82 ± 0.55 AU) and B (2.59 ± 0.57 AU) as compared with group C (2.26 ± 0.63 AU) and D (2.21 ± 0.50 AU) (ANOVA $p<0.05$). In the patients with microvascular complications, the AGE level was 12.6 % higher versus patients without microvascular complications ($p=0.04$, ns after adjustment for age). Overall a weak correlation was observed between AGE and HbA1C levels ($r^2=0.13$, $p<0.001$). No correlation was observed between AGE level and either PWV or IMTc measurements or the duration of diabetes. Adjustment of individual AGE level for age did not change the findings.

Conclusion: In our study, Skin AGE level assessed by AGE Reader was only found correlated with the age of patients but not with microvascular and cardiovascular complications. These findings raise the question of the added value of skin AGE level measurement in the assessment of the mechanisms of macroangiopathy.

1268

Skin autofluorescence and the presence of microvascular and macrovascular complications in patients with type 2 diabetes mellitus: a multicenter study

J.D. Lefrandt¹, M.J. Noordzij¹, T. Brouwer², J. Jager³, M. Castro Cabezas⁴, P.H.N. Oomen⁵, D.J. Mulder¹, A.J. Smit¹

¹Internal Medicine, division of Vascular Medicine, University Medical Center Groningen, ²Internal medicine, Onze Lieve Vrouwe Gasthuis, Amsterdam, ³Internal medicine, Het Diaconessenhuis Meppel, ⁴Internal medicine, division of Vascular Medicine, Sint Franciscus Gasthuis Rotterdam, ⁵Internal medicine, Medisch Centrum Leeuwarden, Netherlands.

Background and aims: Skin autofluorescence (SAF) is a non-invasive marker of accumulation of advanced glycation end products. SAF has been shown to correlate strongly with and to be predictive for both microvascular and macrovascular complications in patients with type 2 diabetes in a single-center primary care cohort. The present cross-sectional study aims to confirm the association between SAF and microvascular and macrovascular complications in patients with type 2 diabetes mellitus in a multicenter secondary care setting.

Materials and methods: We analysed 566 subjects with type 2 diabetes mellitus followed in hospital-based outpatient clinics in 5 Dutch hospitals. Clinical data including micro- and macrovascular complications were gathered.

Results: Median age was 64 years, median duration of diabetes 13 years and median HbA1c 58 mmol/mol. 58% of the patients had microvascular complications (38% had nephropathy, 36% retinopathy, 36% neuropathy), and 42% had macrovascular complications. The median UKPDS 10 years risk for coronary events was 33%. Median SAF was 2.77 which is elevated compared to age-matched healthy controls (median SAF 2.46). More specifically, SAF levels were increased in subjects with diabetic micro- and/or macrovascular complications as compared to the subjects without diabetic complications (median SAF 2.98 for both micro- and macrovascular complications versus 2.84 for macrovascular, 2.79 for microvascular and 2.56 without complications, $p<0.001$). Multivariate analysis showed that the independent determinants of the presence of macrovascular complications were age, serum creatinine, SAF, gender and duration of diabetes. In another model, the level of SAF was determined by age, smoking, serum creatinine, systolic blood pressure and presence of microvascular complications and/or macrovascular complications.

Conclusion: This study confirms that SAF is increased in type 2 diabetic patients, particularly in those with microvascular and macrovascular complications, in a multicenter secondary care setting.

GFT505, a dual PPAR α / δ agonist has beneficial effects in animal models of NAFLD/NASH through PPAR α -dependent and independent mechanisms

R. Hanf¹, A. Rubenstrunk¹, M. Baron², R. Walczak¹, A. Tailleux², D. Hum¹, B. Staels²

¹GENFIT, Loos, ²UMR 1011 - Institut Pasteur, Lille, France.

Peroxisome Proliferator-Activated Receptors (PPARs) α and δ are important regulators of lipid and glucose metabolism and inflammation. GFT505, a dual PPAR α / δ agonist, reduces plasma triglycerides and LDL-cholesterol, increases HDL-cholesterol, improves insulin sensitivity and lowers inflammatory markers in patients with pre-diabetes. In addition, GFT505 improves liver function markers like alanine aminotransferase (ALT) and gamma glutamyl transpeptidase (γ GT). In rodents after oral administration, GFT505 concentrates in the liver with limited extra-hepatic exposures due to an extensive entero-hepatic cycle. Hence, GFT505 may be an interesting candidate to treat non-alcoholic fatty liver diseases (NAFLD) and steato-hepatitis (NASH). We report here on studies assessing the potential of GFT505 in animal models of NAFLD/NASH. Experimental NAFLD/NASH was induced by a 7-week methionine-choline deficient diet (MCDD) in db/db mice. Compared to the control diet, MCDD provoked a large intra-hepatic triglyceride accumulation. At histological examination, a marked macrovesicular and moderate microvesicular steatosis was accompanied by increased inflammation and eosinophilic cytoplasmic inclusions consistent with Mallory bodies. No sign of fibrosis was detected. In MCDD mice concomitantly treated with GFT505 (30 mg/kg/d per os), intra-hepatic triglyceride content was comparable to that measured in mice fed a control diet. Microscopic examination showed that GFT505 administration completely prevented the MCDD induced macrovesicular steatosis. Inflammatory cell foci and eosinophilic inclusions were no longer observed. Consistent with the liver protection by GFT505, plasma ALT activity was comparable in GFT505+MCDD and control groups while it was 3–4 fold higher in mice fed MCDD alone. Quantitative PCR experiments showed that the MCDD-induced rise in expression of inflammatory and pro-fibrosis genes (IL1 β , TNF α , TGF β , collagens) was blocked by GFT505. All these effects of GFT505 were also observed in C57Bl/6 mice fed a MCDD. To assess the role of PPAR δ activation in the beneficial effects of GFT505, dyslipidemic ApoE2-KI mice deficient for PPAR α expression were fed a high fat diet with or without GFT505 (30 mg/kg/d per os) for 6 weeks. Compared to the control group, GFT505 treatment reduced intra-hepatic triglycerides. This correlated with reduced micro- and macrovacuoles and lower cellularity in sinusoids (Kupffer cells). Furthermore, GFT505 treatment significantly reduced expression of inflammatory and pro-fibrosis genes like IL1 β , TNF α , TGF β and collagens. Taken together with the clinical data, these pre-clinical studies argue for the potential of a mixed PPAR α / δ agonist like GFT505 in the prevention or treatment of NAFLD/NASH. These results highlight the role of PPAR δ activation in the hepatic protection provided by GFT505.

1270

Increased dietary polyunsaturated fatty acid is significantly associated with a lower prevalence of steatosis in patients with type 2 diabetes

J.-M. Petit^{1,2}, B. Guiu³, L. Duvillard³, V. Jooste³, M. Brindisi³, A. Athias³, B. Bouillet³, P. Buffier³, J. Cercueil³, B. Verges³

¹Diabetologie, CHU du Bocage, ²INSERM U866, ³INSERM U866, CHU du Bocage, Dijon, France.

Background and aims: Non-alcoholic fatty liver disease (NAFLD) is commonly associated with obesity, metabolic syndrome and type 2 diabetes. Although dietary fat is an important contributor of liver fat accumulation, the role of individual fatty acid in the development of liver fat content is unclear. In this study, we set out to determine whether liver fat content (LFC), was associated with red blood fatty acid composition in people with type 2 diabetes. **Materials and methods:** 162 type 2 diabetic patients were included in this study. LFC was measured using ¹H-MR Spectroscopy; hepatic steatosis was defined as LFC $\geq 5.5\%$. Red blood fatty acid composition was measured by chromatography. Erythrocyte fatty acid composition reflects recent dietary intake (approximately the past 2 months). We also evaluated the saturation index (SI) by the ratio of saturated to monounsaturated fatty acid (palmitic acid to palmitoleic acid). The SI reflects the activity of several genes involved

in lipid metabolism such as stearoyl coenzyme -A desaturase. Fatty acid composition was reported as the percentage by weight of the total fatty acids in the erythrocytes membrane. The fatty acids compositions were categorized into quartiles. Logistic regression models were used to calculate odds ratios as estimates of the relative risks for steatosis associated with each quartile of fatty acids. Age, BMI and gender were included in the multivariate analysis.

Results: 109 (67.2%) patients had steatosis. Patients with steatosis had a higher BMI ($p = 0.0005$), higher plasma ALAT levels ($p < 0.001$), and higher plasma triglyceride levels ($p = 0.009$) than did patients without steatosis. We report a significant association between palmitic acid (16:0), palmitoleic acid (16:1n-7) concentrations and higher liver fat content. Total polyunsaturated fatty acid (PUFA), homo- γ -linolenic acid (20:3n-6), docosahexaenoic acid (22:6n-3), arachidonic acid (20:4 n-6) were associated with lower liver fat content. The SI was significantly associated with higher liver fat content.

Conclusion: The increased SI and palmitoleic acid concentration in subject with steatosis suggests that stearoyl-coA desaturase activity and lipogenesis were increased in these patients. Our data showed that an increased dietary PUFA is significantly associated with a lower prevalence of steatosis in patients with type 2 diabetes. These results suggest that PUFA supplementation could be a promising treatment for NAFLD in patient with type 2 diabetes.

The effect of SFN on hepatic lipogenesis and fibrosis

I.-K. Lee¹, H.-A. Seo¹, A.-K. Min¹, C. Oh¹, H.-J. Kim¹, J.-Y. Kim¹, K.-U. Lee²; ¹Internal Medicine, Kyungpook National University School of Medicine, Daegu, ²Internal Medicine, University of Ulsan College of Medicine, Seoul, Republic of Korea.

Background and aims: Sterol regulatory binding protein-1c (SREBP-1c) and transforming growth factor (TGF)- β /Smad signaling pathways are master regulators of lipogenic and fibrogenic gene expression and promote hepatic steatosis and fibrosis, respectively which are closely associated with insulin resistance. Suforaphane (SFN), an abundant isothiocyanate found in cruciferous vegetables is a potent activator of anti-oxidant Nrf2 protein. However, the effects of SFN on hepatic lipogenesis and fibrosis have not been investigated. Here, we examined whether SFN regulates SREBP-1c expression and TGF- β /Smad signaling pathway in liver.

Materials and methods: Northern and Western blot analyses were performed to examine the potential effects of SFN and Ad-Nrf2 on expression of SREBP-1c, collagen and fibronectin in liver cell lines (H4IIE, HepG2, AML12). Transient transfection study was performed to assess the effect of SFN and Nrf2 on SREBP-1c promoter activity and (CAGA)₃ MLP-Luc, a synthetic TGF- β /Smad3 responsive reporter. The effect of Ad-Nrf2 on LXR-DNA binding activity was determined by electrophoretic mobility shift assay. The in vivo effects of SFN and Ad-Nrf2 on hepatic lipogenesis and fibrosis were verified in high fat diet (HFD)-fed mice and in bile duct ligated (BDL) mice, respectively. **Results:** Overexpression of Nrf2 and SFN inhibited insulin or LXR agonist-stimulated SREBP-1c expression and its promoter activity. SFN also inhibited TGF- β -stimulated collagen and fibronectin expression. Nrf2 also inhibited LXR-agonist-stimulated LXR-DNA binding to its response consensus element on SREBP-1c promoter. Moreover, tail vein injection of Ad-Nrf2 in HFD-fed mice inhibited hepatic steatosis through inhibition of SREBP-1c expression. SFN administration also reduced BDL-induced hepatic fibrosis.

Conclusion: This study shows that SFN exerts a protective effect against hepatic lipogenesis and fibrosis through downregulation of SREBP1c and TGF- β -induced ECM proteins.

Increased selenoprotein P levels in subjects with visceral obesity and non-alcoholic fatty liver disease

H. Choi, H. Hong, M. Cho, Y. Kim, J. Kim, C. Eun, S. Yang, H. Yoo, H. Kim, J. Seo, N. Kim, S. Kim, S. Baik, D. Choi, K. Choi; Endocrinology and Metabolism, Korea University College of Medicine, Seoul, Republic of Korea.

Background and aims: Selenoprotein P (SeP) has recently been reported as a novel hepatokine that regulates insulin resistance and systemic energy metabolism in rodents and humans. We explored the associations between SeP, visceral obesity, and non-alcoholic fatty liver disease (NAFLD).

Materials and methods: We examined serum SeP concentrations in subjects with increased visceral fat area (VFA) or liver fat accumulation measured

using computed tomography (CT). Our study subjects included 120 non-diabetic healthy individuals. In addition, we evaluated the relationship between SeP and cardiometabolic risk factors, including homeostasis model of insulin resistance (HOMA-IR), high sensitivity C-reactive protein (hsCRP), adiponectin values, and brachial-ankle pulse wave velocity (baPWV).

Results: Subjects with NAFLD showed increased levels of HOMA-IR, hsCRP, VFA, and several components of metabolic syndrome and decreased levels of adiponectin and HDL-cholesterol compared to those of controls. Serum SeP levels were positively related to VFA, hsCRP, and baPWV and negatively related to the liver attenuation index. Not only subjects with visceral obesity but also those with NAFLD exhibited significantly increased SeP levels ($P < 0.001$). In multiple logistic regression analysis, the subjects in the highest SeP tertile showed a higher risk for NAFLD compared to those in the lowest SeP tertile, even after adjusting for potential confounding factors (odds ratio = 7.48, 95% CI = 1.72–32.60, $P = 0.007$).

Conclusion: Circulating SeP levels are increased in subjects with NAFLD as well as in those with visceral obesity and may be a novel biomarker for NAFLD.

Visceral adipose tissue-derived serine protease inhibitor is not different in patients with atherosclerosis or diabetes but is associated with severity of peripheral arterial disease

S. Zenz¹, C. Hoebaus¹, M. Ursli¹, D. Lörant^{1,2}, R. Koppensteiner¹, J.M. Brix³, G. Scherthaner³, A. Kurtaran⁴, G.-H. Scherthaner¹;

¹Medicine II, Medical University of Vienna, ²Anaesthesia/Intensive Care Medicine, Medical University of Vienna, ³Medicine I, Rudolf Foundation Hospital, Vienna, ⁴Nuclear Medicine, Rudolf Foundation Hospital, Vienna, Austria.

Background and aims: Visceral adipose tissue-derived serine protease inhibitor (Vaspin), a unique insulin-sensitizing adipocytokine in obesity, has been attributed to be involved in the development of insulin-resistance mediated type 2 diabetes mellitus (T2DM) as well as consecutive atherosclerosis. Even more, a T2DM independent effect on the ontogeny of atherosclerosis was suspected. However, evidence for Vaspin's role in atherosclerosis is scarce and conflicting. Thus we investigated Vaspin levels in patients with different disturbances of glucose metabolism and systemic atherosclerosis (SA) as well as in age- and gender matched controls (CO).

Materials and methods: We investigated Vaspin values in 234 SA patients (66±10 years, 49% female, 30% normal glucose tolerance (NGT), 35% pre-diabetes (PRE), 36% T2DM) and 66 CO (65±11 years, 55% female) by ELISA (BioVendor, Modrice, Czech Republic). Statistics (SPSS 18.0) included KS-Test, t-test, χ^2 -Test, ANOVA and uni/multivariate regression, as appropriate. Non-parametric variables were log10-transformed for normal distribution. Data are given as median (25;75 percentile). A p-value <0.05 was significant.

Results: In contrast to previous smaller studies, Vaspin did not differ between SA and CO patients (181 (120;345) vs 237 (129;339) ng/l, $p=0.256$). In addition, further analysis revealed no difference between the groups CO, SA-NGT, SA-PRE, and SA-T2DM. We observed a significant difference in gender: female 244 (138;397) vs male 176 (113;259) ng/l, $p=0.002$. Vaspin was not associated with levels of thyroid hormones such as Thyroid-Stimulating-Hormone, Free T3, and Free T4. In order to exclude overestimation of as-

sociations in our cohort at highest possible cardiovascular risk, we divided patients (SA) in three Vaspin Tertiles. In all SA patients Vaspin Tertiles were associated with age, fasting insulin, aspartate-amino-transferase, gamma-glutamyl-transferase, gender, stage of peripheral arterial disease (PAD), smoking, and medication with beta-blockers, but not with history or stage of coronary heart disease, stroke, medications with other anti-hypertensive drugs, anti-lipidemic or anti-glycemic medication or obesity or any anthropomorphic characteristics of the latter such as weight-to height or waist-hip ratio. Multivariate stepwise backward regression analysis revealed that gender ($\beta = -0.196$, $p = 0.003$), stage of PAD ($\beta = 0.164$, $p = 0.011$), smoking ($\beta = 0.135$, $p = 0.037$), and medication with beta-blockers ($\beta = 0.165$, $p = 0.011$) together explained Vaspin. **Conclusion:** We clearly demonstrate that in our cross-sectional study Vaspin was not related to parameters of obesity. Among characteristics of pre-/diabetes, Vaspin was only associated with fasting insulin. Among all parameters of atherosclerosis such as staging and events, Vaspin only correlated with the rather subjective clinical staging of PAD after Fontaine but not with ankle-brachial index. Thus, we doubt a role of Vaspin in human clinical overt atherosclerosis as well as in manifest obesity of elderly patients.

Adiposity and diabetic status influences PLA2 isoforms in human abdominal subcutaneous and omental adipose tissue

W. Kumsaiyai¹, A.L. Harte¹, P. Saravanan¹, I. Kyrou¹, N. Aldaghri², S. Kumar¹, G. Tripathi¹, P.G. McTernan¹

¹Division of Metabolic & Vascular Health, Coventry, UK, ²Biochemistry Department, King Saud University, Riyadh, Saudi Arabia.

Background and aims: Lipoprotein-associated phospholipase A2 (Lp-PLA2) is a member of the phospholipase A2 family of enzymes that hydrolyse phospholipids. It is upregulated in conditions of arterial inflammation and CVD, with macrophages considered the major source. Secreted soluble Lp-PLA2 (sPLA2) is known to directly increase arterial inflammation whilst cytosolic calcium dependent PLA2 (cPLA2) and calcium independent PLA2 (iPLA2) appear to contribute to this inflammation through production of lipid mediators. Limited analysis has however examined conditions of obesity, type 2 diabetes mellitus (T2DM), with previous studies suggesting adiposity correlates with Lp-PLA2 activity and metabolic risk. Therefore, in the present study, we sought to understand the role of the adipocyte through the following: (1) characterising Lp-PLA2 gene expression by microarray and qRT-PCR in human matched paired lean and obese abdominal subcutaneous (Abd Sc) and omental (Abd Om) adipose tissue (AT) (2) determining Lp-PLA2 gene expression in cellular fractions of human Sc and Om AT (3) identifying the protein expression of cPLA2 and iPLA2 in lean and obese matched paired human Abd Sc and omental Abd Om AT (4) evaluating the role of lipids and inflammatory markers on circulating sPLA2 levels in subjects with and without obesity and T2DM.

Materials and methods: Serum was taken from lean, (44.4±6.2yr; BMI: 22.6±2.1kg/m², n=15) overweight (45.4±12.3yr; BMI: 27.1±1.6kg/m², n=20) obese (49.0±9.1yr; BMI: 34.5±3.9kg/m², n=13) and T2DM subjects (53.0±6.13yr; BMI: 43.9±7.0kg/m², n=13). AT (n=21) was taken from the same subjects for the gene and protein analysis by qRT-PCR and western blotting, respectively.

Results: Microarray expression of Lp-PLA2 from paired human Abd Sc and Om AT (lean, n=5; BMI, 23.0±1.2 kg/m²; obese, n=5; BMI, 33.2 ± 3.1 kg/m²) highlighted that Lp-PLA2 expression was increased in obesity and was significantly altered in Abd Sc AT ($p < 0.001$); whilst smaller changes were noted in Om AT. Subsequent qRT-PCR analysis confirmed microarray findings with both Abd Sc and Abd Om AT increased in obesity by 2 and 1.5 fold respectively (Abd Sc Lean: ΔCt 17.79±0.04 Vs Abd Sc Obese: ΔCt 16.75±0.06, $P < 0.001$; Abd Om Lean: ΔCt 18.13±0.71 Vs Abd Om Obese: ΔCt 17.51±0.52; $P < 0.05$) with Lp-PLA2 gene expression higher in Abd Sc than Om AT. Lp-PLA2 gene expression in isolated Sc and Om adipocytes and cultured Sc and Om pre-adipocytes was assessed. cPLA2 protein expression increased with obesity in Abd Sc AT ($p < 0.05$) and depot specific protein expression was measured for iPLA2 across lean, overweight and obese AT samples ($p < 0.05$). Serum Lp-PLA2 significantly correlated with insulin ($r = -0.554$, $p < 0.05$) and leptin ($r = 0.727$, $p < 0.01$) in the obese group, whilst in T2DM subjects Lp-PLA2 inversely correlated with HDL ($r = -0.628$, $p < 0.01$).

Conclusion: Our data highlight that the adipocyte is an active source of Lp-PLA2 which is increased in obesity and altered in an abdominal depot specific manner. Furthermore, in obesity, circulating levels of sPLA2 are influenced by insulin and leptin and inversely correlated with HDL in T2DM. Taken together, these data suggest that in addition to macrophage induced sPLA2

the adipocyte itself may represent a further active site of Lp-PLA2 activity which is altered in an insulin resistant state affecting both lipid metabolism and the inflammatory response.

Metabolic profile in women with Dunnigan-type partial familial lipodystrophy caused by R482W mutation in the LMNA gene

M.C. Foss-Freitas¹, L.Z. Monteiro¹, F.B. Coeli¹, F.A. Pereira¹, R.M. Montenegro Junior², M.C. Foss¹

¹Department of Internal Medicine - Division of Endocrinology and Metabolism, Ribeirao Preto School of Medicine - Sao Paulo University, Ribeirao Preto, ²Faculty of Medicine of the Federal University of Ceara - UFC, Brasil, Fortaleza, Brazil.

Background and aims: Lipotrophic diabetes, also referred to as Dunnigan-Type Partial Familial Lipodystrophy (LPFD), is a rare disease, metabolically characterized by hypertriglyceridemia and insulin resistance. Mutations within the LMNA gene on chromosome 1q21-q23 were recently reported to result in the phenotype of familial partial lipodystrophy. The objective of the present study was to evaluate and compare the metabolic profile of women with and without type 2 diabetes mellitus (T2DM) diagnosed with LPFD.

Materials and methods: A quantitative, descriptive cross-sectional study was conducted on 13 women diagnosed with LPFD followed at the Clinic of Endocrinology and Metabolism - Ribeirão Preto Medical School, Brazil: 08 with and 05 without T2DM, with the determination of anthropometric variables (weight, height, BMI and abdominal circumference). Blood was collected after a 12-h overnight fast for analysis of glucose, glycated hemoglobin (HbA_{1c}), insulin, total cholesterol (TC), triglycerides (TG), HDL cholesterol and uric acid.

Results: Data were analyzed using SAS/STAT software. The Wilcoxon test was used to compare the characteristics of the participants. The data for women with T2DM were: age: 40±12 years, weight: 60.4±3.61 kg, height: 1.60±0.05 m, BMI: 23.6±2.1 kg/m², abdominal circumference: 79±3.5 cm and for those without T2DM (NT2DM), age: 28.4±16.4 years, weight: 57.6±8.09 kg, height: 1.63±0.04 m, BMI: 21.7±1.9 kg/m², abdominal circumference: 73±3.8 cm. There was significant difference between women with T2DM regarding glucose (T2DM: 180.3±79.6 mg/dl vs NT2DM: 78.2±5.81 mg/dl $p < 0.05$), HbA_{1c} (T2DM: 8.8±2.4% vs NT2DM: 6.4±2%; $p < 0.05$), insulin (T2DM: 44.2±29.6 µU/ml vs NT2DM: 27.1±30.1 µU/ml; $p < 0.05$), TG (T2DM: 354.7±207.9 mg/dl vs NT2DM: 207±94.7 mg/dl; $p < 0.05$). There was no significant difference regarding TC (T2DM: 193.7±49 mg/dl vs NT2DM: 209.6±64.6 mg/dl), HDL (T2DM: 37.6±4.1 mg/dl vs NT2DM: 37±6.6 mg/dl) and uric acid (T2DM: 5.1±1.5 mg/dl vs NT2DM: 5.6±1.3 mg/dl).

Conclusion: The present data demonstrate that dyslipemia is an early and prominent feature in the presented lipodystrophic family carrying the R482W mutation within LMNA. Therefore, LMNA encoding lamin A/C may play a role in the genesis of familial combined hyperlipidemia. A better understanding of this rare disease may also have broad clinical implications for the pathological mechanism of common diseases such as dyslipemia and insulin-resistant diabetes mellitus.

NT-pro brain natriuretic peptide levels increase during low calorie diet in the obese but return to baseline during weight maintenance unrelated to changes in cardiac function or structure

M.J. Ekman¹, M. Stagmo², A.P.H. Danielsson¹, F. Norström¹, M. Klintenberg¹, B. Israelsson², M. Ridderstråle¹;

¹Clinical Sciences - Diabetes and Endocrinology, Lund University, Malmö,

²Clinic of Cardiology, Skåne University Hospital, Malmö, Sweden.

Background and aims: Brain natriuretic peptide (BNP) levels are increased in subjects with heart failure due to increased myocyte stretch, and are monitored for diagnosis and prognosis. Paradoxically, obese subjects have shown to have lower levels of BNP compared to lean without relation to heart structure or function. Additionally, a lipolytic action, potentiated during low calorie diet (LCD), has been described. The role for BNP as a biomarker in obese subjects with heart failure has been debated and lower cut-off values are suggested. The aim of this study was to examine the variance in the levels of the BNP N-terminal cleavage equivalent, NT-proBNP, in obese subjects during LCD-induced weight loss and after a period of weight maintenance and to assess its relation to body composition as well as metabolic and echocardiographic measurements.

Materials and methods: 18 obese but otherwise healthy subjects (4 men, 14 women; mean \pm SEM age 38 ± 2.6 years) were recruited. Fasting blood samples were collected and OGTT, body composition measurement as well as echocardiography ($n=12$) were performed before and after a 3 month LCD period (800–880 kcal/day; protein 25–30 E%, carbohydrates 49–55 E%, fat 20–21 E%) and after a 6 month follow up period.

Results: BMI decreased during the LCD period (43.3 ± 1.3 to 35.8 ± 1.8 kg/m², $p=0.0015$) and was maintained during the follow up period (-0.064 kg/m², $p=0.97$). Immediate post weight loss evaluation showed lower levels of blood lipids, lower fasting insulin levels, and lower basal metabolism measures compared to the weight maintenance phase, indicating a more catabolic state. NT-proBNP increased during weight loss (63.4 ± 12.4 to 110.2 ± 26.2 pg/ml, $p=0.033$) but returned to baseline values during weight maintenance (-49.0 pg/ml, $p=0.0047$). Left ventricular mass adjusted for height (LVMI) decreased during weight loss (49.4 ± 3.6 to 36.9 ± 2.6 g/m^{2.7}, $p=0.043$) but increased again slightly during weight maintenance ($+5.0$ g/m^{2.7}, $p=0.043$). All subjects had a preserved systolic function based on left ventricular ejection fraction (LVEF) and this remained stable (60.3 ± 2.2 to 59.2 ± 1.7 % during weight loss, $p=0.39$; $+0.67$ % points during weight maintenance, $p=0.92$). The E/E' index (peak early diastolic blood flow velocity over the mitral annulus [E max]/mean mitral annulus tissue velocity [E' lateral and E' septal]), which relates to the diastolic function, did not change during the study (7.1 ± 0.53 to 6.4 ± 0.59 , $p=0.25$ during weight loss; $+0.53$ during weight maintenance, $p=0.93$).

Conclusion: We show that the increase in BNP during weight loss seems to be associated with the catabolic state during LCD unrelated to the kilograms lost per se, since the levels return during weight maintenance, and unrelated to changes in heart function or structure. An explanation for these observations could be that natriuretic peptides have an important lipolytic role when energy access is decreased. It might be hypothesized that BNP increases in order to ensure access of fatty acids, the most important energy resource for the myocardium, during weight loss. More research on the relation of BNP levels to intake of fat or other sources of energy is needed. Our findings show that not only BMI but also current weight loss should be considered when evaluating BNP levels in obese.

The relation between eicosapentaenoic acid and factors of atherosclerosis and inflammation in diabetic patients

K. Nagai, A. Sato, T. Kunugi, M. Era, K. Sakai, Y. Iwamoto;
Diabetes mellitus center, Tokyo Women's Medical University, Japan.

Background and aims: Eicosapentaenoic acid (EPA) is an omega-3 fatty acid, which is obtained in the human diet by fish oil. Several reports suggested that EPA prevented atherosclerosis with multiple biological functions depending on lipid or not. Recently, the Japan EPA lipid intervention study reported that long-term treatment with EPA made 22% decreased in the coronary artery

disease (CAD) in impaired glucose patients as compared to 18% decreased in healthy people. It is not clear the mechanisms of EPA to prevent CAD in diabetic patients. The aim of this study is to investigate the relation between plasma EPA level and factors of atherosclerosis and inflammation in diabetic patients without lipid treatment.

Materials and methods: Forty-seven diabetic patients without treatment of anti-hyper lipidemic drugs such as statins and fibrates (males; 47%, age; 58 ± 17 years (mean \pm SD)) were recruited and measured fasting plasma EPA and arachidonic acid (AA) levels. We interviewed number of days eating fish per week, and history of CAD and stroke. Pulse wave velocity (PWV), ankle brachial pressure index (ABI) and intima-media thickness (IMT) were performed as factors of atherosclerosis. The left ventricular (LV) structure and function were measured by echocardiography, and the LV mass index (LVMI) was calculated using Penn's formula. To assessed factors of inflammation, WBC, CRP, h-CRP, and IL-6 were measured.

Results: Average EPA was 44.6 ± 20.8 μ g/ml, AA was 146.2 ± 33.6 μ g/ml, EPA/AA ratio was 0.31 ± 0.14 , and all parameters were normal range. Average number of intake fish was 3.4 ± 2.4 times/week, and was positively correlated with EPA and EPA/AA ($p<0.008$, $p<0.009$, respectively). EPA and EPA/AA were negatively correlated with total number of white blood cell (WBC 5962 ± 1990 / μ l), while CRP, h-CRP, and IL-6 were not correlated significantly. Average HbA1c was 8.9 ± 2.4 %, LDL-C 115 ± 27 mg/dl, HDL-C 49 ± 14 mg/dl, triglyceride 126 ± 64 mg/dl. There was not significantly correlation between EPA and lipids or HbA1c. Moreover, there was no correlation EPA and PWV, ABI, IMT, and LV structure and function.

Conclusion: It suggests EPA may play a role of inflammation system to prevent CAD, independent on lipid and glucose metabolism.

Organ-specific candidate biomarkers of inflammation found by comparative analyses of the human hepatic and adipose tissue transcriptome and secretome during LPS treatment

R.J. Vonk¹, E. Szalowska¹, M. Dijkstra¹, D. Weening¹, M. de Vries¹, H. Roelofs¹, M. Bruinenberg², A. Hoek³, M.G.L. Elferink⁴, G.M.M. Groothuis⁴;

¹Medical Biomics, UMCG, ²Department of Genetics, UMCG, ³Department of Obstetrics and Gynecology, UMCG, ⁴Division Pharmacokinetics, Toxicologie and Targeting: Department of Pharmacy, University, Groningen, Netherlands.

Background and aims: Insulin resistance (IR) is accompanied by chronic low grade systemic inflammation and deregulation of total body energy homeostasis. We induced inflammation in human adipose and human liver tissue *in vitro* in order to mimic inflammation *in vivo* with the aim to identify tissue-specific processes implicated in IR and to find biomarkers indicative for tissue-specific IR.

Methods: Human adipose and liver tissues were cultured in the absence or presence of LPS and DNA Microarray Technology was applied for their transcriptome analysis. Gene Ontology (GO), gene functional analysis, and prediction of genes encoding for secretome were performed using publicly available bioinformatics tools (DAVID, STRING, SecretomeP). The transcriptome data were validated by proteomics analysis of the inflamed adipose tissue secretome using CILAIR technology.

Results: LPS treatment significantly affected 667 and 484 genes in adipose and liver tissues respectively. The GO analysis revealed that during inflammation adipose tissue, compared to liver tissue, had more significantly up-regulated genes, GO terms, and functional clusters related to inflammation and angiogenesis. The secretome prediction led to identification of 399 and 236 genes in adipose and liver tissue respectively. The secretomes of both tissues shared 66 genes and the remaining genes were the differential candidate biomarkers indicative for inflamed adipose or liver tissue. The transcriptome data of the inflamed adipose tissue secretome showed excellent correlation with the proteomics data.

Conclusions: The higher number of altered proinflammatory genes, GO processes, and genes encoding for secretome during inflammation in adipose tissue compared to liver tissue suggests that adipose tissue is the major organ contributing to the development of systemic inflammation observed in IR. The identified tissue specific functional clusters and biomarkers might be used in a strategy for the development of tissue-targeted treatment of IR patients.

Higher plasma high-mobility group box 1 levels are associated with incident cardiovascular disease and all-cause mortality in type 1 diabetes: a 12-year follow-up study

J.W.M. Nin¹, A. Jorsal^{2,3}, I. Ferreira^{1,4}, C.G. Schalkwijk^{1,5}, M.H. Prins^{6,4}, H.-H. Parving^{7,8}, L. Tarnow², P. Rossing², C.D.A. Stehouwer^{1,5};

and Public Health Research Institute (CAHRI), Netherlands, ⁷Medical

Endocrinology, Rigshospitalet, Copenhagen, Denmark, ⁸Faculty of Health

Science, Aarhus University, Denmark.

Background and aims: High-mobility group box 1 (HMGB1) is a pro-inflammatory cytokine that may contribute to the pathogenesis of vascular complications commonly observed in diabetes. In a cross-sectional study in patients with type 1 diabetes we found serum HMGB1 levels to be positively associated with albuminuria, but not with prevalent cardiovascular disease (CVD). In the present study, we investigated whether plasma HMGB1 levels are associated with incident CVD and all-cause mortality in type 1 diabetes, and the extent to which any such associations could be explained by low-grade inflammation (LGI), endothelial and renal dysfunction, and pulse pressure (PP, a marker of arterial stiffness).

Materials and methods: We prospectively followed 165 individuals with diabetic nephropathy and 168 individuals with persistent normoalbuminuria who were free of CVD at study entry and in whom levels of HMGB1 and other biomarkers were measured at baseline. We used linear and Cox proportional hazards regression analyses adjusted for age, sex, duration of diabetes, case-control status, HbA1c, body mass index, smoking status, total cholesterol, mean arterial pressure, and antihypertensive medication.

Results: Plasma levels of Ln-HMGB1 were not associated with markers of LGI, endothelial and renal dysfunction, and PP. During the course of follow-up [median: 12.3 years (7.8–12.5)], 80 individuals died; 82 suffered a fatal (n=46) and/or nonfatal (n=53) CVD event. Incident fatal and nonfatal CVD and all-cause mortality increased with higher baseline plasma levels of Ln-HMGB1: HR=1.55 (95%CI: 0.94; 2.48) and HR=1.86 (1.18; 2.93) per unit increase in Ln-HMGB1, respectively. Further adjustments for LGI, endothelial and renal dysfunction, and PP did not attenuate these associations.

Conclusion: Plasma HMGB1 levels are positively associated with incident all-cause mortality in type 1 diabetes, independently of conventional cardiovascular risk factors and markers of several potential HMGB1-related pathophysiological mechanisms. To a lesser extent, higher plasma HMGB1 levels are also associated with incident CVD. Thus, HMGB1 may explain, in part, the increased risk of CVD and mortality in these patients. However, the positive association between plasma HMGB1 and incident CVD observed in the present study together with our earlier finding of no association between serum HMGB1 levels and prevalent CVD may suggest that serum levels and plasma levels of HMGB1 do not represent the same pool of HMGB1. Further studies are needed to clarify both the interrelationship between serum and plasma levels of HMGB1, and their associations with CVD.

Might increased alpha- and beta-defensin levels contribute to the pathogenesis of diabetic complications?

T.T. Várkonyi¹, B. Németh², F. Somogyvári², R. Laurentzi¹, A. Szegedi¹, R. Takács¹, C. Lengyel¹, P. Kempler³, Y. Mándi², T. Wittmann¹;

¹1st Department of Medicine, University of Szeged, ²Department of Medical

Microbiology and Immunobiology, University of Szeged, ³1st Department of

Medicine, Semmelweis University, Budapest, Hungary.

Background and aims: As defensins are involved in inflammatory and proatherogenic processes, their possible role in the pathogenesis of diabetic micro- and macroangiopathy is also assumed. The aim of this study was to analyse the genetic characteristics and the plasma levels of alpha- and beta-defensins in diabetic patients.

Materials and methods: 98 type 1 and 135 type 2 diabetic patients and 221 controls were tested. The plasma levels of alpha-defensin, the expression of alpha-defensin mRNA and the gene copy numbers of defensin alpha1- alpha3

(DEFA1A3) were measured. Three single nucleotide polymorphisms (SNPs) of the beta-defensin 1 were analyzed. ELISA, real-time PCR, Taq-Man based real-time PCR and Custom TaqMan[®] SNP genotyping method were applied. **Results:** The plasma levels of alpha-defensin were higher in both types of diabetes than in the control group (type 1 vs control: 29030±5650 vs 11940±2960 pg/ml, p<0.001; type 2 vs control: 29800±6010 vs 11940±2960 pg/ml, p<0.001, mean±SEM). The highest concentrations of alpha-defensin were found in diabetic patients with nephropathy (49200±1300 pg/ml vs. 23500±900 pg/ml; with vs without nephropathy; p<0.05), neuropathy (36500±4900 pg/ml vs 25700±3500 pg/ml; with vs without neuropathy; p<0.05) or with cardiovascular complications (45600±1450 pg/ml vs 24500±2500 pg/ml; with vs without cardiovascular complications, p<0.05). The higher alpha-defensin values did not correlate with the DEFA1A3 copy numbers, the mRNA expression or the HbA1c in diabetic patients. Two of the three SNPs of beta-defensin 1 (G20A and G52A) in diabetic patients did not differ from the controls, while the frequency of the GG genotype in the SNP of C-44G allele was lower in both types of diabetes than the controls (2.5% vs 9.5%, p<0.01). This difference was more pronounced in patients with neuropathy or nephropathy compared to controls (1.2% vs 9.5%, p<0.01 and 1.5% vs 9.5%, p<0.01). The CC genotype of C-44G SNP was more frequent among diabetic patients than in the controls (65% vs 50%, p<0.05).

Conclusion: Diabetic patients had increased alpha-defensin levels, the highest values were observed in patients with micro- or macrovascular complications. The presence of certain alleles of beta-defensin 1 seems to be protective against nephropathy or neuropathy in both types of diabetes. These data support a hypothesis that both alpha- and beta-defensins might have an important role in the pathogenesis of diabetic complications.

Vitamin D deficiency is associated with endothelial dysfunction, in subjects with type 2 diabetes

H.L. Gulseth^{1,2}, K. Angel^{3,2}, C. Wium^{1,2}, E.F. Eriksen^{1,2}, K.I. Birkeland^{1,2};

¹Dep of Endocrinology, Oslo University Hospital, ²Institute of Clinical

Medicine, University of Oslo, ³Dep of Cardiology, Oslo University Hospital,

Norway.

Background and aims: Cardiovascular disease is prevalent in subjects with type 2 diabetes, and both arterial stiffness and endothelial dysfunction may contribute in the pathogenesis. Moreover, epidemiological studies suggest that low levels of vitamin D are associated with both type 2 diabetes and cardiovascular disease. We therefore evaluated possible predictors of aortic stiffness and endothelial function in subjects with type 2 diabetes.

Material and methods: Endothelial function was assessed by measuring the reactive hyperaemia index (RHI) using endothelial pulse amplitude testing (Endo-PAT). Aortic stiffness was estimated as carotid-femoral pulse wave velocity (cfPWV) with applanation tonometry (SphygmoCor) and insulin sensitivity measured with the euglycaemic, hyperinsulinaemic clamp. 25-hydroxy-vitamin D (25(OH)D) was measured using the DiaSorin radioimmunoassay.

Results: Subjects (n=34, 65 % males) were of Nordic (n=24) and South-Indian (n=10) ethnicity and their mean (SD) age was 57.1 (10.2) years, BMI 31.0 (5.1) kg/m², HbA1c 7.6 (1.3)% and diabetes duration 10.3 (6.1) years, 56.7 % had microalbuminuria and all had 25(OH)D <50 nmol/L. Mean (SD) 25(OH)D was 38.4 (8.5) nmol/L, insulin sensitivity, measured as the glucose infusion rate, 734 (436) µmol/m²/min, cfPWV 10.1 (1.9) m/s and RHI 1.77 (0.43). cfPWV correlated positively with age (r=0.46, p=0.008), BMI (r=0.48, p=0.005), systolic blood pressure (0.53, p=0.002) and mean arterial pressure (r=0.43, p=0.01). In multivariate regression analysis, only age (β=0.064, p=0.02) and BMI (β=0.141, p=0.008) were predictors of cfPWV (model R=0.73). Endothelial dysfunction correlated positively with age (r=0.37, p=0.03) and 25(OH)D (r=0.54, p=0.001), and in multivariate regression analysis only 25(OH)D (β=0.019, p=0.03) predicted RHI (model R=0.49). Vitamin 25(OH)D differed significantly across tertiles of RHI (figure 1), p=0.012, with the lowest concentrations in those with the most impaired endothelial function. Insulin sensitivity, HbA1c, diabetes duration and microalbuminuria did not predict cfPWV or endothelial dysfunction.

Conclusion: In subjects with type 2 diabetes, age and BMI predicted aortic stiffness (aPWV) and only 25(OH)D predicted endothelial dysfunction (RHI). Vitamin D seems to be a potential modifier of endothelial function, but not aortic stiffness, in subjects with type 2 diabetes.

Vitamin 25(OH)D across tertiles of RHI

University Medical Center Groningen, Netherlands.

Background and aims: Plasma procalcitonin (PCT) is a known biomarker of bacterial sepsis. More recently, PCT variation at lower plasma levels has been suggested as a new biomarker for chronic low-grade inflammation which is associated with obesity and atherosclerosis. We aimed to investigate whether plasma PCT is related to cardiovascular and all-cause mortality in patients with type 2 diabetes.

Materials and methods: This study is part of the ZODIAC study, a prospective observational study amongst patients with type 2 diabetes treated in primary care in the Netherlands. A total of 1192 patients, who started to participate between 1998 and 2002 were included in the study. Blood was drawn for future research. In 2009 life status and cause of death were assessed. The relationship between PCT and mortality was investigated using Cox proportional hazard analyses. The analyses were performed with PCT categorised into quintiles and also as a continuous variable. Three models were chosen: a crude model, a model in which was adjusted for age and gender and finally a model in which we additionally adjusted for BMI, serum creatinine, smoking, diabetes duration, systolic blood pressure, cholesterol HDL ratio, history of macrovascular complications and albuminuria. PCT and serum creatinine were logarithmically transformed because of skewed distribution of the data. All analyses were performed after excluding PCT values above 0.1 ng/ml (n=8).

Results: Mean age of the study cohort was 66.7 ± 11.6 years, and 521 (43.7%) patients were male. Median [interquartile range] PCT level was 0.020 [0.014-0.022] ng/mL. Further baseline data include a median HbA1c of 53 [45-65] mmol/mol, diabetes duration of 4 [2-9] years, estimated creatinine clearance of 72 [57-91] mL/min and urinary albumin creatinine ratio of 1.92 [0.93-6.58] mg/mmol. After median follow-up of 9.8 years, 348 (29%) out of 1191 patients had died. The unadjusted Hazard Ratio (HR) for all-cause mortality was 1.88 (95% CI 1.33-2.65) for patients in the highest quintile (>0.024 ng/mL) of PCT compared to the lowest quintile. In the second and third model these HRs were 1.39 (95% CI 0.98-1.96) and 1.16 (95% CI 0.80-1.68), respectively. For PCT on a continuous scale, the unadjusted HR for logPCT was 1.74 (95% CI 1.34-2.27). In the second and third model these HRs were 1.43 (95% CI 1.09-1.88) and 1.22 (95% CI 0.91-1.63), respectively. For CV mortality, the HRs for logPCT were 1.62 (95% CI 1.08-2.43), 1.34 (95% CI 0.88-2.05) and 0.79 (95% CI 0.50-1.25) in model 1, 2 and 3, respectively. The HRs for the highest PCT quintile compared to the lowest were 1.89 (95% CI 1.12-3.19), 1.42 (95% CI 0.84-2.40) and 0.83 (95% CI 0.47-1.47) in model 1, 2 and 3, respectively.

Conclusion: Elevated plasma PCT levels, in the normal range, were associated with mortality. However, this relationship is to a large extent confounded by well-established risk factors in patients with type 2 diabetes. Based on the confidence intervals, a small independent relation between PCT and mortality cannot be fully excluded.

Osteoprotegerin and coronary artery disease in type 2 diabetic patients with microalbuminuria

H. Reinhard¹, M. Nybo², P.R. Hansen³, N. Wiinblad⁴, A. Kjaer⁵, C.L. Petersen⁴, K. Winther⁶, L.M. Rasmussen², H.-H. Parving⁷, P. Rossing¹, P.K. Jacobsen⁸;

¹Steno Diabetes Center, Gentofte, ²Department of Clinical Biochemistry and Pharmacology, University Hospital, Odense, ³Department of Cardiology, University Hospital, Gentofte, ⁴Department of Clinical Physiology and Nuclear Medicine, University Hospital, Frederiksberg, ⁵Department of Clinical Physiology, Nuclear Medicine & PET and Cluster for Molecular Imaging, Rigshospitalet, Copenhagen, ⁶Department of Clinical Biochemistry, University Hospital, Frederiksberg, ⁷Department of Medical Endocrinology, University Hospital, Copenhagen, ⁸The Heart Centre, Rigshospitalet, Copenhagen, Denmark.

Background and aims: Plasma osteoprotegerin (P-OPG) is a strong and independent predictor of cardiovascular disease (CVD) in diabetic and other populations. OPG is a bone-related glycopeptide produced by vascular smooth muscle cells and increased P-OPG may reflect arterial damage. We investigated the correlation between P-OPG and coronary artery disease (CAD) in asymptomatic type 2 diabetic patients with microalbuminuria.

Methods: P-OPG was measured in 200 asymptomatic type 2 diabetic patients without previous cardiac disease. Patients with P-NT-proBNP >45.2 ng/L and/or coronary calcium score (CCS) ≥ 400 were stratified as high risk of CAD (n=133), and all other patients as low risk patients (n=67). High risk patients were examined by myocardial perfusion imaging (MPI; n=109), and/or CT-angiography (n=20), and/or coronary angiography (CAG; n=86). Significant CAD was defined by presence of significant myocardial perfusion defects at MPI or $>70\%$ coronary artery stenosis at CAG.

Results: Significant CAD was demonstrated in 70 of the 200 patients and of these 23 patients had $>70\%$ coronary artery stenosis at CAG. P-OPG was higher in patients with significant CAD compared to patients without CAD (n=130). Increased P-OPG was an independent predictor of significant CAD (adjusted odds ratio [CI] 3.51 [1.39-8.86] and 3.54 [1.36-9.21] for second and third tertile vs. first tertile P-OPG, respectively) and remained so after adjustments for NT-proBNP and CCS. The area under the receiver-operating curve in a model for prediction of significant CAD changed from 84% to 87%, when P-OPG was added to the model. High P-OPG was also associated with presence of $>70\%$ coronary artery stenosis (adjusted odds ratio 14.20 [1.35-148.92] for third vs. first tertile P-OPG), and 91% of patients with low (first tertile) P-OPG did not have $>70\%$ coronary artery stenosis.

Conclusions: Elevated P-OPG is an independent predictor of the presence of CAD in asymptomatic type 2 diabetic patients with microalbuminuria.

Chemerin is independently associated with albuminuria in type 2 diabetic patients

C. Kim¹, S. Yu¹, J. Kang¹, O. Ryu¹, S. Lee¹, S. Ihm¹, E. Lee², M. Choi¹, H. Yoo¹;

¹Dept. of Endocrinology Hallym University Sacred Heart Hospital, Anyang,

²Yonsei University College of Medicine, Severance Hospital, Seoul, Republic of Korea.

Background and aims: Chemerin is a recently discovered metabolic regulator hormone. Moreover, chemerin has been suggested to be linked to obesity-induced insulin resistance and type 2 diabetes. Diabetic nephropathy is a serious microvascular complication of diabetes mellitus. The decrease in renal function of diabetic nephropathy is characterized by elevated urinary albumin excretion. Recently, serum chemerin levels were found to be significantly associated with renal dysfunction in type 2 diabetic patients. However, the association of plasma chemerin levels with albuminuria is unknown yet. The aim of the study was to determine whether serum chemerin levels are associated with albuminuria in type 2 diabetic patients.

Materials and methods: One hundred two patients with type 2 diabetes were enrolled. These patients were newly diagnosed with type 2 diabetes and were drug naïve. Blood pressure, body mass index (BMI), waist circumference (WC) and serum concentration of A1C, glucose, insulin, lipid profile, hsCRP, and chemerin were measured. Insulin resistance was estimated by the short insulin tolerance test. Visceral fat thickness was determined by ultrasonography. Urine albumin excretion (UAE) was assessed as albumin:creatinine ratio in early-morning urine samples. The glomerular

filtration rate (GFR) was calculated using the Cockcroft and Gault formula. Serum levels of chemerin were measured by enzyme-linked immunosorbent assay.

Results: The clinical characteristics of the control group and the diabetic group are presented in Table 1. No differences were found in levels of chemerin between female and male. Serum chemerin level was significantly correlated with BMI ($r=0.343$, $p<0.001$), WC ($r=0.36$, $p=0.001$), VFT ($r=0.390$, $p<0.001$), insulin ($r=0.452$, $p=0.000$), triglyceride ($r=0.295$, $p=0.003$), HDL-cholesterol ($r=-0.318$, $p=0.002$), hsCRP (log-transformed, $r=0.263$, $p=0.037$) and UAE (log-transformed, $r=0.275$, $p=0.007$). Moreover, after adjustment for glucose, blood pressure, multiple regression analysis showed that serum chemerin was significantly associated with urine albumin excretion ($\beta=0.256$, $p=0.011$).

Conclusion: Serum chemerin is another important independent factor associated with albuminuria in type 2 diabetic patients.

Table 1. Clinical and biochemical characteristics of type 2 diabetic patients

	Female	Male	P-value
N	39	63	
Age (years)	51.4 ± 11.3	46.4 ± 9.1	0.017

Neuronal and glial changes induced by type 1 diabetes in the rat hippocampus

J.M. Gaspar^{1,2}, F.I. Baptista², Á.F. Castilho², J. Liberal², J. Gonçalves^{3,4}, A.F. Ambrósio^{2,5}

¹CEDOC, Faculdade Ciências Médicas, Lisbon, ²Centre of Ophthalmology and Vision Sciences, Coimbra, ³Laboratory of Pharmacology and Experimental Therapeutics, Coimbra, ⁴Institute of Biomedical Research on Light and Image (IBILI), Coimbra, ⁵Centre for Neuroscience and Cell Biology, Coimbra, Portugal.

Background and aims: Long-term diabetes can result in a variety of subtle cerebral disorders with manifestations demonstrated at structural, neurochemical, electrophysiological and neurobehavioural level. Cognitive and memory impairments associated with diabetes result from modification of hippocampal structure and function, including changes in neuronal and glial cells. The aim of this work was to further evaluate and identify changes in hippocampal neuronal and glial cells induced by diabetes at different time points along the early stages of the disease (two, four and eight weeks).

Materials and methods: Diabetes was induced in male Wistar rats with a single intraperitoneal injection of streptozotocin. Neurodegeneration and apoptosis was evaluated by cresyl violet staining and detection of caspase-3. Neuronal changes were assessed by evaluating the immunoreactivity of microtubule associated protein-2 (MAP-2) and synaptophysin, as well as the protein content of Tuj-1, calbindin D28k and tau. Astrocyte reactivity was analyzed by measuring the content and immunoreactivity of glial fibrillary acidic protein (GFAP). Changes in microglial cells were evaluated with CD11b and ED1 markers.

Results: No signs of neurodegeneration or caspase-3 activation were detected in the hippocampus of diabetic animals. However, a decrease in the protein levels of all neuronal markers occurred after eight weeks of diabetes. Regarding MAP-2 immunoreactivity, there was a decrease in dentate gyrus at all time points of the study, and after eight weeks a decrease occurred in all hippocampal subregions (CA1, CA3 and dentate gyrus). Synaptophysin immunoreactivity increased in CA3 subregion at all time points. No changes were detected in astrocyte reactivity in diabetic animals. However, the number of activated microglia increased in dentate gyrus and CA3 subregion at eight weeks of diabetes.

Discussion: These observations indicate that diabetes does not induce neuronal degeneration in the hippocampus, at least during the early stages of the disease. However, neuronal changes occur, mainly after longer periods of diabetes (eight weeks), and CA3 subregion appears to be the most affected region. Moreover, astrocytes did not become reactive with diabetes, at least for the time points studied, but microglial cells became activated, suggesting the existence of a pro-inflammatory response. Altogether, these changes might affect cognitive and memory performance.

Cerebrospinal fluid Alzheimer's disease markers in adult type 1 diabetes patients: associations with microangiopathy and APOE ε4

N.S.M. Schoonenboom¹, E. van Duinkerken^{2,3}, R.G. IJzerman², M.A. Blankenstein⁴, L.W. van Golen², M. Klein³, F.J. Snoek³, P. Scheltens¹, M. Diamant²

¹Department of Neurology, ²Diabetes Centre / Department of Internal Medicine, ³Department of Medical Psychology, ⁴Department of Clinical Chemistry, VU University Medical Centre, Amsterdam, Netherlands.

Background and aims: Type 1 diabetes (T1DM), especially in the presence of peripheral microangiopathy, is associated with cognitive decrements and cerebral structural changes. Cognitive deficits are mainly found in domains concerning information processing speed and structural brain loss has been observed in grey matter. Furthermore, diabetes in general has been associated with a 2-fold higher risk of dementia in later life, including vascular dementia and Alzheimer's Disease (AD), possibly mediated by apolipoprotein E (APOE) ε4 genotype. Cerebrospinal fluid (CSF) amyloid-β1-42 (Aβ42), total tau and tau phosphorylated at threonine 181 (p-tau-181) are usually changed in dementia. Amyloid deposition is found extracellular and can impair neu-

ronal signaling, leading to cell death. Hyperphosphorylated tau tangles are found intracellular and are a marker of neuronal death. For example, in AD, A β 42 concentrations are decreased whereas tau and ptau-181 are increased. These changes are already present during the early phase of AD. Presently, it is unknown whether these biomarkers are altered in T1DM patients and whether these changes are related to the presence of microangiopathy and APOE ϵ 4.

Materials and methods: Ten patients with (mean age 48.5 years; mean HbA1c 7.5%; mean disease duration 35.6 years), 28 without peripheral microangiopathy (mean age 40.5 years; mean HbA1c 7.8%; mean disease duration 22.8 years) and 15 controls (mean age 39.9 years; mean HbA1c 5.4%), on T1DM versus control level matched for age, gender, BMI and IQ, were included in this study. They underwent a lumbar puncture at L3/L4 or L4/L5 for CSF collection and blood sampling for APOE genotyping. To enhance power we analysed T1DM patients as whole group compared to controls.

Results: Patients with peripheral microangiopathy were oldest and had most depressive symptoms, compared to the other groups. All 3 CSF biomarkers for AD were not changed in T1DM patients compared to controls, although ptau-181 tended to be increased ($P=0.1$). In T1DM patients with APOE ϵ 4 genotype, A β 42 concentrations were lower compared to those without the APOE ϵ 4 genotype ($P=0.033$), which was not observed in controls. Microangiopathy presence did not alter CSF biomarker concentrations.

Conclusion: This sample of T1DM patients with a mean age of 42 years did not show a AD-like profile of decreased CSF A β 42 and increased total tau and ptau-181 levels. However, in T1DM patients with APOE ϵ 4, a significant decrease in A β 42 concentration was observed. In these patients, amyloid deposition in increased compared to their non-APOE ϵ 4 counterparts, which may result in impaired neuronal signaling and cell death. Whether CSF biomarker concentrations change over time and what their predictive value for cognitive functions is, has to be further detailed.

Cognition in type 1 diabetes mellitus

B. Szémán¹, G. Nagy¹, A. Somogyi¹, T. Varga¹, D. Fitala¹, A. Szöllösi¹, A. Veres-Székely², R. Katonai³, M. Sasvári³, E. Kotyuk²;

¹2nd Department of Internal Medicine, Semmelweis University, ²Faculty of Education and Psychology, Eötvös Lóránd University, ³Institute of Medical Biochemistry, Semmelweis University, Budapest, Hungary.

Background and aims: Individuals with diabetes are approximately 1.5-fold more likely to experience cognitive decline than individuals without diabetes. Several neuropsychological tests are used to assess multiple cognitive domains. The Stroop Neuropsychological Screening Test and Wisconsin Card Sorting Test (WCST) are widely used in clinical practice and research to examine selective attention, cognitive flexibility, processing speed, the ability to learn concepts, and used as a tool in the evaluation of executive functions. Our aims were to investigate differences in cognitive function between patients with type 1 diabetes mellitus (T1DM) and healthy controls (C), and evaluate the association between cognitive dysfunction and glycemic control in patients.

Materials and methods: 50 T1DM and 50 C were screened for cognitive function with the computerized version of the Stroop test and the WCST. Depression was evaluated with the Hospital Anxiety and Depression Scale. Interview questionnaires surveyed the detailed anamnesis and medication. Anthropometry and metabolic parameters were measured. The computerized version of the original Stroop test recorded congruent and incongruent trials reaction time and calculated the Stroop effect reaction time (SERT). The WCST has shown total number of errors, number of perseverative errors to describe mental flexibility.

Results: The Stroop test showed that the SERT (DMSERT:112.8 \pm 74.16ms), the congruent RT (DMCRT:828.69 \pm 99.3ms) and the incongruent RT (DMICRT:941.58 \pm 127.37ms) of the T1DM group were significantly ($p<0.01$) longer than the C group SERT (CSERT:64 \pm 53.4ms), congruent RT (CCRT:661.44 \pm 85.7ms), and incongruent RT (CICRT:725.38 \pm 85.7ms). A statistically significant association was observed between the HbA1C (7.76 \pm 1.75%) levels and the score on Stroop effect ($p=0.028$). In WCST the rate of correct answers (80.25 \pm 7.55) was negative significantly ($p=0.022$) correlated with duration of T1DM. The two groups were age-adjusted (Cage: 32.18 \pm 11.75yr; T1DMage:35.62 \pm 11.65yr).

Conclusion: T1DM is associated with cognitive deficit, which can be related to many different regions of the brain. Our results indicate that T1DM show impaired executive functions and information-processing speed. Chronic

poorly controlled carbohydrate metabolism might have a role in the development of selective attention deficit. Optimal diabetes care can improve the motor speed, attention and executive function.

Poor glycaemic control is associated with cognitive dysfunction in older adults with type 2 diabetes

S.A. Milrad, E. Lopez Gonzalez, A. Garcia, A. Luongo, M.L. Ruiz, M. Khoury, M.C. Varela, DECOYDI GROUP; Argentinian Society of Diabetes, Buenos Aires, Argentina.

Background and aims: Type 2 Diabetes (DM2) is associated with a high risk of Cognitive Dysfunction (CD) and dementia. The relationship between glycemic control and cognitive function remains unclear. We analyze the association between glycemic control (A1c) and cognitive dysfunction in older adults with DM 2 without a diagnosis of dementia.

Materials and methods: Patients with DM ≥ 65 years old were studied. The study was carried out by 17 Argentinean doctors specialized in Diabetes from the states of Buenos Aires, Salta and Buenos Aires City (Argentina). The evaluation included the following items: duration of diabetes, treatment and complications of diabetes type 2, level of education, income, habits, anthropometric measures and laboratory tests. The metabolic control was measured by A1c value. Cognitive function was evaluated by the test Mini Mental State Examination (MMSE), (normal 28-30, cognitive dysfunction ≤ 27 points) and depression by the Yessavage depression scale (considered pathologic > 9 points). Statistical Analysis: Chi2, Wilcoxon Test and Multiple Logistic Regression. Software Intercooled STATA 9.0.

Results: 427 patients were studied, female 55.2%, age 71.83 \pm 5.58 years, duration of diabetes 11.78 \pm 9.17 years, glycemia 128 \pm 42.19 mg/dl, A1c 7.15 \pm 2.73 %, BMI 29.71 \pm 5.65 Kg/m2. CD was present in 225 patients (52.7%), and Depression in 79 (18.5%). Education level ≤ 7 years 178 (41.7%), monthly income ≤ 300 euros 116 (27.2%), Alcohol consumption 208 (48.7%), smoking 30 (7.0%), obesity 167 (39.1%) and living alone 63 (14.8%) of the patients. Treatment: 24 patients (5.6%) were without pharmacological treatment, 271 patients (63.5%) with anti-diabetic oral medication and 132 (30.9%) with insulin alone or combined with oral medication. History of hypoglycemia was present in 82 patients (19.2%), dyslipidemia in 370 (86.7%), Hypertension in 376 (88.1%), peripheral arterial disease in 39 (9.1%), coronary disease in 87 (20.4%), carotid disease in 56 (13.1%). The Hb A1c > 7 was associated with CD: rough OR=1.56; CI 95%=1.05-2.33; $p=0.02$. When A1c was adjusted by age, sex, income, education, obesity, physical activity, depression, hypertension, tobacco, alcohol, work, living alone and dyslipidemia, the A1c showed an adjusted OR=1.67; CI95%=1.01-2.76; $p=0.04$. Forward Stepwise Logistic regression was used to identify the predictors for CD. The protective variables were: living alone, (OR: 0.50; CI: 0.28-0.94; $p < 0.03$) and obesity (OR: 0.62; CI:0.40-0.96; $p < 0.03$). The following variables were identified as risk factors for cognitive dysfunction: A1c (OR= 0.52; CI:0.28-0.94; $p<0.02$), depression (OR= 1.80; CI: 1.03-3.15; $p<0.03$), Low income (OR = 2.37-4.03; $p < 0.002$) and less education level (OR= 3.71; CI:2.35-5.86; $p < 0.0001$).

Conclusion: Cognitive dysfunction was found to be a common occurrence in a sample of older diabetic individuals. In this population, the A1c > 7 was associated with CD. Poor glycemic control, low education level, lower income and depression were also identified as risk factors for CD. These findings need to be validated in prospective studies.

Obesity of the bone: the relationships between body mass, adiposity and bone density in children: a 7-year longitudinal study

A.J. Streeter, J. Hosking, B.S. Metcalf, M.B.A. Mostazir, A.N. Jeffery, L.D. Voss, T.J. Wilkin; Endocrinology and Metabolism, Peninsula Medical School, Plymouth, UK.

Background and aims: Osteoporosis and obesity share a common progenitor cell, and osteoporosis has been dubbed 'obesity of the bone'. Indeed, osteoporosis is a well-recognised co-morbidity of diabetes, itself largely attributable to obesity. Peak bone mass is an important determinant of osteoporosis, but there is little information on the impact of body composition and metabolic health on bone growth in children.

Materials and methods: The relationship between fatness and bone mineral density (BMD) was investigated annually in 307 healthy children from 5–12y in a prospective cohort study. Fatness was measured by serum leptin (ng/ml) and BMD (g/cm^2) by dual-energy x-ray absorptiometry (DEXA). Leptin was chosen as a measure of fatness for three reasons - it derives exclusively from adipocytes, its concentration is independent of fat-free mass, and it correlates closely with adiposity. BMI (m/kg^2) was deduced from duplicate measures of height and weight and converted to BMI sds, a standardised measure of weight excess. The association between BMD and leptin for each gender and year of growth was analysed using covariance-pattern modelling, controlling for age-related growth and fat-free mass.

Results: BMD ($0.02 \text{ g}/\text{cm}^2$ per year), BMI SDS (0.14 units/year) and serum leptin ($1.5 \text{ ng}/\text{ml}$ per year) all rose annually throughout. There was a clear positive association ($p < 0.001$) between BMD and leptin in both genders from 5y to 8y, with BMD rising on average by $0.009 \text{ g}/\text{cm}^2$ in boys and $0.006 \text{ g}/\text{cm}^2$ in girls, for every $10 \text{ ng}/\text{ml}$ increase of leptin. However between the ages of 8y and 9y the direction of association changes to a negative trend with BMD decreasing on average by $0.002 \text{ g}/\text{cm}^2$ in boys and $0.001 \text{ g}/\text{cm}^2$ in girls for every $10 \text{ ng}/\text{ml}$ increase of leptin.

Conclusions: Diabetes is associated with loss of bone, believed to result from fatty infiltration of the medulla. Although BMD and leptin as BMI sds (excess body fat) continued to rise with age, the initial positive relationship between BMD and leptin is inverted between the ages of 8y and 9y. This inversion may reflect the earliest stages of 'obesity of the bone'.

Quantitative ultrasound and vertebral fractures in patients with type 2 diabetes

T. Yamaguchi, M. Yamamoto, I. Kanazawa, M. Yamauchi, S. Yano, T. Sugimoto;

Internal Medicine 1, Shimane University, Izumo, Japan.

Background and aims: Patients with type 2 diabetes (T2DM) are known to have increased risks of femoral neck and vertebral fractures, although their bone mineral density (BMD) is normal or even slightly increased compared to non-DM controls. This observation suggests that bone fragility not reflected by BMD, possibly deterioration of bone quality, may participate in their fracture risks. Quantitative ultrasound (QUS), not like BMD, could possibly evaluate bone quality, especially microarchitecture, and therefore might be useful for assessing fracture risk in T2DM.

Materials and methods: To test this hypothesis, we measured calcaneal QUS as well as BMD at the lumbar spine, femoral neck, and 1/3 radius in 96 women (mean age, 66.6 years old) and 99 men (64.7 years old) with T2DM, and examined their associations with prevalent vertebral fractures (VFs). Calcaneal QUS was performed by CM-200, and speed of sound (SOS) values were obtained. BMD was measured by QDR4500.

Results: In T2DM patients, VFs were found in 33 and 45 subjects in women and men, respectively. When compared between subjects with and without VFs, there were no significant differences in values of SOS or BMD at any site between the groups in either gender. The distribution of SOS as a function of age showed that those with VFs were scattered widely and there were no SOS thresholds for VFs in either gender. Logistic regression analysis adjusted for age and BMI showed that either SOS or BMD was not significantly associated with the presence of VFs in either gender.

Conclusion: These results show that QUS as well as BMD are unable to discriminate T2DM patients with prevalent VFs from those without VFs. It seems necessary to seek other imaging modalities or biochemical markers evaluating bone fragility and fracture risk in T2DM.

1291

The correlation between HbA_{1c} and risk of femoral fractures in elderly patients

T.H.K. Puar, J.M. Ng, R.Y. Chen, L.W. Cho;

Endocrinology, Changi General Hospital, Singapore.

Background and aims: Elderly patients with type 2 diabetes mellitus (T2DM) are at greater risk of falls as a result of chronic hyperglycaemic complications, such as retinopathy and neuropathy, or secondary to treatment-induced hypoglycaemia. Previous studies have shown that tight glycaemic control ($\text{HbA}_{1c} < 7.0\%$) is closely related to an increased risk of falls. The

present study sought to evaluate the relationship between glycaemic control and diabetes therapy with the incidence of hip fractures in a tertiary hospital in Singapore.

Materials and methods: All patients with T2DM who were admitted in a 12 month period from Dec 2009 to Dec 2010 inclusive for a low energy hip fracture were included in the analysis. Patients on diet control or newly diagnosed with diabetes on admission were excluded from the study. Clinical details and data from the study were obtained from the hospital laboratory database and discernment of medical notes.

Results: There were a total of 129 patients (88 female, 41 male, mean age 77.1 ± 9.4) included in the study. Median HbA_{1c} was 6.6% (Inter-Quartile Range $6.0\%-7.4\%$). The patients were divided into 4 groups, Group A ($\text{HbA}_{1c} < 6.5\%$), Group B ($\text{HbA}_{1c} 6.5-7.0\%$), Group C ($\text{HbA}_{1c} 7.1-8.0\%$) and Group D ($\text{HbA}_{1c} > 8\%$). The results of the study are summarised in Graph 1. There were significantly more patients with hip fractures in Group A (45.0%) compared with Group B (20.9%), Group C (16.3%) and Group D (17.8%). The patients in Group A were also older (mean age 79.4 ± 8.4) compared to Group B (77.2 ± 9.7 , $p=0.30$), Group C (75.4 ± 8.9 , $p=0.07$), and significantly older than Group D (72.8 ± 10.6 , $p=0.004$) using independent t test. Crucially, a high proportion of these patients in Group A were also receiving sulphonylureas (SU) or insulin therapy (41 of 58, 70.7%), 22 on SU monotherapy, 18 on SU in combination with metformin or acarbose, and 1 on SU with insulin.

Conclusion: Sulphonylureas are associated with an increased risk of hypoglycaemia, particularly in the elderly. Furthermore, low HbA_{1c} values have been shown to increase the risk of falls and hypoglycaemic attacks in this population. While glycaemic targets are set at $< 7\%$, or $< 6.5\%$ for most, the American Geriatrics Society has suggested a less stringent HbA_{1c} therapeutic target of 8% for frail elderly patients. Despite this, the present study shows that nearly half of elderly patients admitted with hip fractures had very tight glycaemic control ($\text{HbA}_{1c} < 6.5\%$). Hip fractures are associated with a high mortality rate in the subsequent years. Hence, prevention of this is of paramount importance. 82.2% of patients who sustained a hip fracture in the present study were on sulphonylureas and / or insulin therapy, of which nearly half had HbA_{1c} values $< 6.5\%$ (38.7%). Although a relationship between hip fractures and the risk of hypoglycaemia in this case can only be inferred, it is clear that there is a need for less stringent glycaemic control in the elderly. Primary physicians need to tailor diabetes therapy based on the side effects profile of intended drugs and to individualised treatment targets in each patient.

Incidence of Hip Fractures in DM Patients on medications

1292

The impact of modifiable factors on hearing function in diabetic subjects

M. Dabrowski¹, G. Niedzińska², A. Nowakowski³;

¹Diabetic Outpatient Clinic, NZOZ "Beta-Med", Rzeszow, ²Department of Pediatric Otolaryngology, Phoniatry and Audiology, Medical University in Lublin, ³Department of Endocrinology, Medical University in Lublin, Poland.

Background and aims: Sense of hearing is a very important tool of social communication. Hearing impairment prevalence in diabetic subjects is roughly doubled in comparison with a general population. The aim of our

interdisciplinary study was to assess whether some modifiable factors, like HbA_{1c}, blood pressure, serum lipids and BMI have an impact on auditory organ function in the relatively young diabetic subjects.

Materials and methods: 58 patients, 31 with type 1 diabetes and 27 with type 2 diabetes, aged below 45 years, with a diabetes duration < 10 years, and without clinically overt hearing impairment or diabetic neuropathy, were included. After vital signs and blood samples for laboratory evaluations were obtained, patients were referred to the audiological lab, where a pure-tone audiometry and transiently-evoked otoacoustic emissions (TEOAE) were evaluated. Hearing threshold ≥ 25 dB in at least 1 frequency was recognized as hearing impairment. TEOAE amplitude < 6 dB was considered as an absence of otoacoustic emissions.

Results: 38 patients had a normal hearing. The hearing impairment was found in 20 subjects (34.5 %). These patients had a significantly lower HDL-cholesterol level (44.2 ± 13.4 mg/dl vs. 57.6 ± 13.1 mg/dl, $p < 0.001$) and a higher BMI (29.6 ± 6.3 kg/m² vs. 25.5 ± 6.4 kg/m², $p = 0.011$) in comparison with normal-hearing subjects (Figure). A trend towards higher triglycerides was also observed (132.4 ± 79.5 mg/dl vs. 93.6 ± 59.8 mg/dl, $p = 0.059$). No significant differences between the 2 groups regarding HbA_{1c}, blood pressure and LDL-cholesterol were found. Normal TEOAE amplitude was found in 42 subjects. Absence of otoacoustic emissions was diagnosed in 16 subjects (27.6 %). Also these patients had a lower HDL-cholesterol level (45.4 ± 16.6 mg/dl vs. 55.2 ± 13.2 mg/dl, $p = 0.018$) (Figure). No significant differences between the 2 groups regarding other variables were demonstrated. In the linear correlations analyses, a significant negative relationship between hearing threshold and HDL-cholesterol (at frequencies from 1000 Hz to 12,000 Hz), as well as positive correlation between hearing threshold and triglycerides (at frequencies from 1000 Hz to 4000 Hz), BMI (from 2000 Hz to 12,000 Hz) and systolic blood pressure (SBP) (at 2000 Hz and 3000 Hz) were found. Also significant positive correlation between TEOAE amplitude and HDL-cholesterol ($r = 0.333$, $p = 0.014$), and a negative correlation between TEOAE amplitude and triglycerides ($r = -0.277$, $p = 0.043$) were demonstrated.

Conclusion: Hearing impairment is frequent in diabetic subjects. Our study revealed that several modifiable factors like HDL-cholesterol, triglycerides, SBP and BMI may affect hearing function in this population. If these results were confirmed in further studies, a vast area of possible therapeutic interventions to preserve hearing in diabetic patients would open.

Figure. Histogram plot of HDL-cholesterol level and BMI value in patients with hearing impairment and normal hearing; and in subjects with absent and present otoacoustic emissions.

1293

Screening on a wide scale and profile of the sleep apnoea syndrome in type 2 diabetes patients

A. Iosup, H. Banciu, H. Sahla, J.-P. Courrèges;
General Hospital, Narbonne, France.

Background and aims: An effective screening of the sleep apnoea syndrome (SAS) in particular in type 2 diabetes patients (T2D) is impaired by the lack of specificity of the clinical manifestations and the fact that it is not easy to perform a polysomnography on a wide scale. Does the use of pulse oximetry ease the SAS wide scale screening?

Materials and methods: A pulse oximetry has been performed in 586 T2D overweight (BMI ≥ 27 kg/m²) patients disconnected from an emergency hospitalization or an obvious pulmonary pathology. Three criteria suggesting a possible SAS were selected: SpO₂ percentage < 90% (at least ≥ 10 %), Oxygen Desaturation Index (ODI) ≥ 10 , time spent at SpO₂ 30 or > 10 10.

Results: 404 (69%) patients show 0 or 1 criterion, 82 (14%) show 2 criteria and 100 (17%) show 3 criteria. Among those last 182 patients (31%) who show at least 2 criteria, 150 could benefit from a polysomnography. SAS diagnosis was confirmed for 116 patients (20%). 40 patients among the 64

showing 2 criteria (62,5%) and 76 patients among the 86 showing 3 criteria (88%) actually suffered from SAS. The analysis of diagnosed SAS profile concludes with an average age of 65.4 yrs, a sex ratio F/M of 1.09, a BMI of 36 kg/m², 27.5% suffer from a severe coronarite. Among the 150 patients, SAS frequency according to the BMI (kg/m²) is: BMI > 27 30 35 40 : 73% + 8 alveolar hypoventilation syndromes (diagnosis of 95% of obvious respiratory troubles). Regarding the oximetry analysis on these SAS patients, the average SpO₂ < 90% is 36.2%; the average ODI is 23, the average time spent under hypoxia (SpO₂ < 90%) is 161 mn, the average SpO₂ is 86%.

Conclusion: The pulse oximetry offers an efficient wide scale screening, realistic and easy to implement whether externally, especially effective if 3 criteria are present. Taking into account SAS frequency (20%) in overweight T2D patients, its well-known cardiac consequences (27% of severe coronary diseases in this series), the importance of hypoxia, this screening technique appears to us as enough relevant to be generalized.

1294

Effect of initiation of continuous positive airway pressure therapy on cardiovascular risk factors in patients with type 2 diabetes and obstructive sleep apnoea

P.C. Myhill¹, W.A. Davis², K. Peters², T.M.E. Davis², D. Hillman³;
¹Endocrinology, Fremantle Hospital, ²School of Medicine and Pharmacology, Fremantle Hospital, Perth, ³Department of Pulmonary Physiology, Sir Charles Gairdner Hospital, Perth, Australia.

Background and aims: Diabetes and obstructive sleep apnoea (OSA) are important co-morbid conditions. In people with diabetes, the prevalence of OSA may be as high as 58%. Continuous Positive Airway Pressure (CPAP) is a highly effective treatment for OSA but there are limited data on the effect of CPAP therapy on OSA in type 2 patients. It is possible that CPAP could improve metabolic control, blood pressure and diabetes-associated complications such as sexual dysfunction in males. We therefore conducted a before-and-after study to determine whether CPAP improves glycaemic control and other cardiovascular risk factors in type 2 patients with confirmed OSA.

Materials and methods: Between April 2009 and March 2010, 59 type 2 diabetes patients from the longitudinal observational Fremantle Diabetes Study considered at high risk for OSA after an overnight home-based sleep study using an ApneaLink had confirmation of the diagnosis by laboratory polysomnography and then consented to participation in a 3-month CPAP intervention study. A detailed medical history, physical examination and biochemical testing were undertaken immediately before, and 1 and 3 months after CPAP commenced. The males completed two sexual dysfunction questionnaires, the sexual health inventory for men and the ADAM questionnaire, on each occasion. Repeated measures statistical analysis was used to compare variables of interest at the three time points.

Results: Forty-four (75%) of the original cohort completed the study. They had a mean \pm SD age of 66.1 ± 8.8 years, 61.4% were male their median [IQR] diabetes duration was 10.1 [3.8–15.3] years, and they had an apnoea hypopnoea index (AHI) of 38 [27–58] and Epworth Sleepiness Scale (ESS) of 9 [5–12] at entry. There were no significant differences between the 44 completers and 15 non-completers in age, sex, diabetes duration, AHI or ESS ($P \geq 0.29$). Blood pressure improved significantly over 3 months of CPAP therapy from $149 \pm 23/80 \pm 12$ mmHg at entry to $140 \pm 18/73 \pm 13$ mmHg (trend $P = 0.038/0.013$). The change in systolic blood pressure (Δ SBP) was -8 (-18 to 1) mmHg, with significant improvement between 1 month and 3 months (Δ SBP -8 (-14 to -1) mmHg, $P = 0.012$). Most improvement in diastolic blood pressure also occurred between months 1 and 3 (Δ DBP -8 (-15 to -1) mmHg, $P = 0.015$). Pulse rate declined significantly within the first month (Δ pulse rate -6 (-10 to -2) beats/minute, $P = 0.001$). Glycaemic control, serum lipids and urinary albumin:creatinine ratio (ACR) did not improve over the study period but most patients had acceptable HbA_{1c} (< 7.0%), LDL-cholesterol (< 2.5 mmol/L) and ACR (< 3.0 mg/mmol) at entry. The ESS decreased significantly over the study period, specifically between entry and 1 month (Δ ESS = -4.8 (-6.5 to -3.1, $P < 0.001$)). Amongst the 27 males, the median number of symptoms of sexual dysfunction decreased significantly over the study period, from 6.5 to 5.5 ($P = 0.008$).

Conclusion: A 3-month trial of CPAP in community-based type 2 patients improved blood pressure, pulse rate, daytime sleepiness, and, in men, sexual function.

European Association for the Study of Diabetes

EASD Executive Committee

President:	U. Smith, SE (retires 2011)
Vice-President:	A.J.M. Boulton, UK (retires 2011)
Vice-President:	F. Bosch, ES (retires 2012)
Honorary Secretary:	M. Walker, UK (retires 2013)
Honorary Treasurer:	G. Spinas, CH (retires 2011)
Chairman of the Postgraduate Education Committee:	C. Tack, NL (retires 2013)
Editor-in-Chief, DIABETOLOGIA:	J. Zierath, SE (retires 2013)

EASD Council comprises of the Officers above and the following members:

Term expiring September 2011	Term expiring September 2012	Term expiring September 2013
T. Battelino, SL	J.-M. Boavida, PT	F. Beguinot, IT
D. Matthews, UK	C.-G. Östenson, SE	J. Dekker, NL
J. Philippe, CH	A. Pfeiffer, DE	F. Karpe, UK
J. Zierath, SE	N. Wareham, UK	V. Urbanavicius, LT

The Past President, E. Ferrannini, and the Secretary of the Postgraduate Education Committee, L. Czupryniak, are members of the Council ex officio.

HONORARY AUDITORS

K. Paterson, UK (retires September 2011); M. Roden, Germany (retires September 2013)

HONORARY MEMBERS

G. Alberti, UK; D. Andreani, IT; J.-P. Assal, CH; E. Cerasi, IL; O.-B. Crofford, USA; A. Czyzyk, PL; T. Deckert, DK; P. Freychet, FR; H. Keen, UK; E. Kohner, UK; P. Lefèbvre, BE; R. Luft, SE; C. Lurie, USA; Carl Erik Mogensen, DK; J. Nerup, DK; L. Orci, CH; G.M. Reaven, USA; J. Pirart, BE; S. Rahbar, USA; J. Roth, USA; E. Shafir, IL; D. Steiner, USA; R. Unger, USA; E. von Wasielowski, DE; W. Waldhäusl, AT; Paul Zimmet, AU

GOLD MEMBERS

Astra Zeneca, Mölndal, Sweden; Bayer HealthCare, Berlin, Germany; Bristol-Myers Squibb, Uxbridge, UK; Eli Lilly & Co., Suresnes, France; GlaxoSmithKline, Uxbridge, UK; Janssen Pharmaceutical NV, Beerse, Belgium; LifeScan, Inc., High Wycombe, UK; Merck & Co. Inc., New Jersey, USA; Novartis Pharma AG, Basel, Switzerland; Novo Nordisk A/S, Bagsvaerd, Denmark; Pfizer Inc. New York, USA; sanofi-aventis, Paris, France; Takeda, London, UK

SILVER MEMBERS

Abbott Diabetes Care, Berks, UK; Arkray Europe, Amstelveen, Netherlands; Boehringer Ingelheim GmbH, Ingelheim, Germany; Daiichi Sankyo Europe GmbH, Munich, Germany; Roche Diagnostics GmbH, Mannheim, Germany

ASSOCIATE MEMBERS

77 Elektronika Ltd., Budapest, Hungary; A. Menarini Diagnostics, Grassano, Italy; Amylin Europe Ltd., San Diego, USA; Becton Dickinson Europe, Pont-de-Claix, France; C8 MediSensors, Inc., San Jose, USA; Dexcom Inc. Lund, Sweden; Medtronic International, Tolochenaz, Switzerland; Owen Mumford Ltd., Oxford, UK; Ypsomed GmbH, Sulzbach, Germany; Merck Serono s.a. Geneva, Switzerland

The EASD Executive Committee is also the Executive Committee of the European Foundation for the Study of Diabetes (EFSD).

EASD/EFSD office : Rheindorfer Weg 3, 40591 Düsseldorf, Germany - www.easd.org
